APPENDIX E: LALR(1) SYNTACTIC GRAMMAR ......................................................... 8686
1 NOTATIONAL CONVENTIONS

1.1 SYNTACTIC AND LEXICAL GRAMMARS

This section describes the context-free grammars used in this specification to define the lexical and syntactic structure of an ECMAScript program.

1.1.1 Context-Free Grammars

A context-free grammar consists of a number of productions. Each production has an abstract symbol called a nonterminal as its left-hand side, and a sequence of one or more nonterminal and terminal symbols as its right-hand side. For each grammar, the terminal symbols are drawn from a specified alphabet. Starting from a sentence consisting of a single distinguished nonterminal, called the goal symbol, a given context-free grammar specifies a language, namely, the (perhaps infinite) set of possible sequences of terminal symbols that can result from repeatedly replacing any nonterminal in the sequence with a right-hand side of a production for which the nonterminal is the left-hand side.

1.1.2 The Lexical Grammar

A lexical grammar for ECMAScript is given in Chapter 3. This grammar has as its terminal symbols the characters of the Unicode character set. It defines a set of productions, starting from the goal symbol Input, that describe how sequences of Unicode characters are translated into a sequence of input elements. These input elements other than white space and comments discarded, form the terminal symbols for the syntactic grammar for ECMAScript and are called ECMAScript tokens. These tokens are the reserved words, identifiers, literals, and punctuators of the ECMAScript language. Moreover, line terminators, although not considered to be tokens, also become part of the stream of input elements and guide the process of automatic semicolon insertion. Simple white space and comments are simply discarded and do not appear in the stream of input elements for the syntactic grammar.

Productions of the lexical grammar are distinguished by having two colons “::” as separating punctuation.

1.1.3 The Numeric String Grammar

A second grammar is used for translating strings into numeric values. This grammar is similar to the part of the lexical grammar having to do with numeric literals and has as its terminal symbols the characters of the Unicode character set. This grammar appears in Chapter 5.

Productions of the numeric string grammar are distinguished by having three colons “:::” as punctuation.

1.1.4 The Syntactic Grammar

The syntactic grammar for ECMAScript is given in Chapters 7, 8, 9, and 10. This grammar has ECMAScript tokens defined by the lexical grammar as its terminal symbols. It defines a set of productions, starting from the goal symbol Program, that describe how sequences of tokens can form syntactically correct ECMAScript programs.

When a stream of Unicode characters is to be parsed as an ECMAScript program, it is first converted to a stream of input elements by repeated application of the lexical grammar; this stream of input elements.
with one extra LineTerminator appended, is then parsed by a single application of the syntax grammar. (The purpose of the extra appended LineTerminator is to ensure that automatic semicolon insertion be operative at the end of the program.) The program is syntactically in error if the tokens in the stream of input elements cannot be parsed as a single instance of the goal nonterminal program, with no tokens left over.

Productions of the syntactic grammar are distinguished by having just one colon “:” as punctuation.

The syntactic grammar as presented in Chapters 7, 8, 9, and 10 is actually not a complete account of which token sequences are accepted as correct ECMAScript programs. Certain additional token sequences are also accepted, namely, those that would be described by the grammar if only semicolons were added to the sequence in certain places (such as before end-of-line characters). Furthermore, certain token sequences that are described by the grammar are not considered acceptable if an end-of-line character appears in certain “awkward” places.

A LALR(1) version of the syntactic grammar is presented in Appendix E. This version provides an exact account of which token sequences are acceptable ECMAScript programs without needing special rules about automatically adding semicolons or forbidding end-of-line characters. However, it is much more complex than the grammar presented in Chapters 7, 8, 9, and 10.

1.1.5 Grammar Notation

Terminal symbols are shown in fixed width font in the productions of all the grammars, and throughout this specification whenever the text directly refers to such a terminal symbol. These are to appear in a program exactly as written.

Nonterminal symbols are shown in italic type. The definition of a nonterminal is introduced by the name of the nonterminal being defined followed by one or more colons. (The number of colons indicates to which grammar the production belongs.) One or more alternative right-hand sides for the nonterminal then follow on succeeding lines. For example, the syntactic definition:

```
WithStatement :  
    with ( Expression ) Statement
```

states that the nonterminal WithStatement represents the token with, followed by a left parenthesis token, followed by an Expression, followed by a right parenthesis token, followed by a Statement. The occurrences of Expression and Statement are themselves nonterminals. As another example, the syntactic definition:

```
ArgumentList :  
    AssignmentExpression  
    ArgumentList , AssignmentExpression
```

states that an ArgumentList may represent either a single AssignmentExpression or an ArgumentList, followed by a comma, followed by an AssignmentExpression. This definition of ArgumentList is recursive, that is to say, it is defined in terms of itself. The result is that an ArgumentList may contain any positive number of arguments. Such recursive definitions of nonterminals are common.

The subscripted suffix “opt”, which may appear after a terminal or nonterminal, indicates an optional symbol. The alternative containing the optional symbol actually specifies two right-hand sides, one that omits the optional element and one that includes it. This means that:

```
VariableDeclaration :  
    Identifier Initializer opt
```

is a convenient abbreviation for:

```
VariableDeclaration :  
    Identifier  
    Identifier Initializer
```

and that:
IterationStatement :
    for ( Expressionopt ; Expressionopt ; Expressionopt ) Statement

is a convenient abbreviation for:

IterationStatement :
    for ( ; Expressionopt ; Expressionopt ) Statement
    for ( Expression ; Expressionopt ; Expressionopt ) Statement

which in turn is an abbreviation for:

IterationStatement :
    for ( ; ; Expressionopt ) Statement
    for ( ; Expression ; Expressionopt ) Statement
    for ( Expression ; ; Expressionopt ) Statement

which in turn is an abbreviation for:

IterationStatement :
    for ( ; ; ) Statement
    for ( ; ; Expression ) Statement
    for ( ; Expression ; ) Statement
    for ( ; Expression ; Expression ) Statement
    for ( Expression ; ; ) Statement
    for ( Expression ; Expression ; ) Statement
    for ( Expression ; Expression ; Expression ) Statement

so the nonterminal IterationStatement actually has eight alternative right-hand sides.

If the phrase “[no LineTerminator here]” appears in the right-hand side of a production of the syntactic grammar, it indicates that the production is a restricted production: it may not be used if a LineTerminator occurs in the input stream at the indicated position. For example, the production:

ReturnStatement :
    return [no LineTerminator here] Expressionopt ;

indicates that the production may not be used if a LineTerminator occurs in the program between the return token and the Expression.

Unless the presence of a LineTerminator is forbidden by a restricted production, any number of occurrences of LineTerminator may appear between any two consecutive tokens in the stream of input elements without affecting the syntactic acceptability of the program.

When the words “one of” follow the colon(s) in a grammar definition, they signify that each of the terminal symbols on the following line or lines is an alternative definition. For example, the lexical grammar for ECMAScript contains the production:

ZeroToThree :: one of
    0       1       2       3

which is merely a convenient abbreviation for:

ZeroToThree ::
    0
    1
    2
When an alternative in a production of the lexical grammar or the numeric string grammar appears to be a multicharacter token, it represents the sequence of characters that would make up such a token.

The right-hand side of a production may specify that certain expansions are not permitted by using the phrase “but not” and then indicating the expansions to be excluded. For example, the production:

\[
\text{Identifier} :: \text{IdentifierName but not ReservedWord}
\]

means that the nonterminal Identifier may be replaced by any sequence of characters that could replace IdentifierName provided that the same sequence of characters could not replace ReservedWord.

Finally, a few nonterminal symbols are described by a descriptive phrase in roman type in cases where it would be impractical to list all the alternatives:

\[
\text{SourceCharacter: any Unicode character}
\]

### 1.2 Algorithm Conventions

We often use a numbered list to specify steps in an algorithm. When the algorithm is to produce a value as a result, we use the directive “return x” to indicate that the result of the algorithm is the value of x and that the algorithm should terminate. We use the notation Result(n) as short hand for “the result of step n”. We also use Type(x) as short hand for “the type of x”. If an algorithm is defined to “generate a runtime error”, execution of the algorithm (and any calling algorithms) is terminated and no result is returned.

These algorithms are used to clarify semantics. In practice, there may be more efficient algorithms available to implement a given feature.
2 SOURCE TEXT

2.1 UNICODE

ECMAScript source text is represented as a sequence of characters representable using the Unicode version 2.0 character encoding.

```
SourceCharacter ::= any Unicode character
```

However, it is possible to represent every ECMAScript program using only ASCII characters (which are equivalent to the first 128 Unicode characters). Non-ASCII Unicode characters may appear only within comments and string literals; in both of those contents, any Unicode character may be expressed as a Unicode escape sequence consisting of six ASCII characters, namely \u plus four hexadecimal digits, and the effect is exactly the same as if the Unicode character itself had appeared in place of the escape sequence. Within a comment, such an escape sequence is effectively ignored as part of the comment; within a string literal, the Unicode escape sequence contributes one character to the string value of the literal.

Note that ECMAScript differs from the Java programming language in the behavior of Unicode escape sequences. In a Java program, if the Unicode escape sequence \u000A, for example, appears to occur within a single-line comment, it is interpreted as a line terminator (Unicode character 000A is line feed) and therefore the next character is not part of the comment. Similarly, if the Unicode escape sequence \u000A occurs within a string literal in a Java program, it is likewise interpreted as a line terminator, which is not allowed within a string literal—one must write \n instead of \u000A to cause a line feed to be part of the string value of a string literal. In an ECMAScript program, a Unicode escape sequence occurring within a comment is never interpreted and therefore cannot contribute to termination of the comment. Similarly, a Unicode escape sequence occurring within a string literal in an ECMAScript program always contributes a character to the string value of the literal and is never interpreted as a line terminator or as a quote mark that might terminate the string literal.

```
SourceCharacter ::= any Unicode character
```

2.1 END OF SOURCE

For purposes of describing the grammar of ECMAScript, the source text is assumed to be terminated by a logical “end of source” character. We represent the end-of-source character by <EOS>.

```
EndOfSource ::= <EOS>
```
3 Lexical Conventions

The source text of a ECMAScript program is first converted into a sequence of tokens and white space. A token is a sequence of characters that comprise a lexical unit. The source text is scanned from left to right, repeatedly taking the longest possible sequence of characters as the next token.

3.1 White Space

White space characters are used to improve source text readability and to separate tokens, (indivisible lexical units) from each other but are otherwise insignificant. White space may occur between any two tokens, and may occur within strings (where they are considered significant characters forming part of the literal string value), but cannot appear within any other kind of token. White space may also occur inside a string, where it is significant.

The following characters are considered to be white space:

<table>
<thead>
<tr>
<th>Unicode Value</th>
<th>Name</th>
<th>Formal Name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Tab</td>
<td>&lt;TAB&gt;</td>
</tr>
<tr>
<td></td>
<td>Vertical Tab</td>
<td>&lt;VT&gt;</td>
</tr>
<tr>
<td></td>
<td>Form Feed</td>
<td>&lt;FF&gt;</td>
</tr>
<tr>
<td></td>
<td>Space</td>
<td>&lt;SP&gt;</td>
</tr>
</tbody>
</table>

Syntax

WhiteSpace ::

SimpleWhiteSpace WhiteSpace opt
LineTerminator WhiteSpace opt
Comment WhiteSpace opt

SimpleWhiteSpace ::

&lt;TAB&gt;
&lt;VT&gt;
&lt;SP&gt;

3.2 Line Terminators

Line terminator characters, like whitespace characters, are used to improve source text readability and to separate tokens (indivisible lexical units) from each other. Unlike whitespace characters, line terminators have some influence over the behavior of the syntactic grammar. In general, line terminators may occur between any two tokens, but there are a few places where they are forbidden by the syntactic grammar. A line terminator cannot occur within any token (not even a string). Line terminators also affect the process of automatic semicolon insertion (see section 0).
The following characters are considered to be line terminators:

<table>
<thead>
<tr>
<th>Unicode Value</th>
<th>Name</th>
<th>Formal Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>\u000A</td>
<td>Line Feed</td>
<td>&lt;LF&gt;</td>
</tr>
<tr>
<td>\u000D</td>
<td>Carriage Return</td>
<td>&lt;CR&gt;</td>
</tr>
</tbody>
</table>

Syntax

LineTerminator ::
   <LF>
   <CR>

LineEnd ::
   LineTerminator
   <EOS>

3.3 Comments

Description

Comments can be either single or multi-line. Multi-line comments cannot nest.

Because a single-line comment can contain any character except a LineTerminator character, and because of the general rule that a token is always as long as possible, a single-line comment always consists of all characters from the // marker to the end of the line. However, the LineTerminator at the end of the line is not considered to be part of the single-line comment; it is recognized separately by the lexical grammar and becomes part of the stream of input elements for the syntactic grammar. This point is very important, because it implies that the presence or absence of single-line comments does not affect the process of automatic semicolon insertion (see section 0).

Syntax

Comment ::
   MultiLineComment
   SingleLineComment

MultiLineComment ::
   /* MultiLineCommentChars_opt */

MultiLineCommentChars ::
   MultiLineNotAsteriskChar MultiLineCommentChars_opt
   * PostAsteriskCommentChars_opt

PostAsteriskCommentChars ::
   MultiLineNotForwardSlashChar MultiLineCommentChars_opt

MultiLineNotAsteriskChar::
   SourceCharacter but not asterisk * or <EOS>

MultiLineNotForwardSlashChar::
   SourceCharacter but not forward-slash / or <EOS>
3.4 Tokens

Syntax

Token ::
  ReservedWord
  Identifier
  Punctuator
  Literal
  EndOfSource

3.4.1 Reserved Words

Description
Reserved words cannot be used as identifiers.

ReservedWord ::
  Keyword
  FutureReservedWord
  NullLiteral
  BooleanLiteral

3.4.2 Keywords

The following keywords are in use in either the Borland ECMAScript implementation, the Netscape 1.1 ECMAScript implementation, the Microsoft JScript implementation or all three.

Syntax

Keyword: one of
  break  continue  delete  else
  for    function  if     in
  new    return   this   typeof
  var    void     while  with

3.4.3 Future Reserved Words

The following words are used as keywords in proposed extensions and are thus reserved to allow for the adoption for those extensions.

Syntax
3.5 IDENTIFIERS

Description

An identifier is a character sequence of unlimited length, where each character in the sequence must be a letter, a decimal digit, an underscore (_), or a dollar sign ($) character, and the first character may not be a decimal digit. ECMAScript identifiers are case sensitive: identifiers whose characters differ only in case are nevertheless considered to be distinct.

Syntax

Identifier ::

IdentifierName but not ReservedWord

IdentifierName ::

IdentifierLetter
IdentifierName IdentifierLetter
IdentifierName DecimalDigit

IdentifierLetter :: one of

a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
$_$

DecimalDigit :: one of

0 1 2 3 4 5 6 7 8 9

3.6 PUNCTUATORS

Syntax

Punctuator :: one of

= > < == <= >=
!= , ! ~ ? :
. & & | | ++ -- +- 
- * / & | ^
% << >> >>> += -= *= /= %=
<<= >>= >>>= ( ) { 
} [ ] ;
3.7 LITERALS

Syntax

```
Literal ::
    NullLiteral
    BooleanLiteral
    NumericLiteral
    StringLiteral
```

3.7.1 Null Literals

Syntax

```
NullLiteral ::
    null
```

Semantics

The value of the null literal `null` is the sole value of the `Null` type, namely `null`.

3.7.2 Boolean Literals

Syntax

```
BooleanLiteral ::
    true
    false
```

Semantics

The value of the Boolean literal `true` is a value of the Boolean type, namely `true`.
The value of the Boolean literal `false` is a value of the Boolean type, namely `false`.

3.7.3 Numeric Literals

Syntax

```
NumericLiteral ::
    IntegerLiteral
    FloatingPointLiteral

IntegerLiteral ::
    DecimalIntegerLiteral
    HexIntegerLiteral
    OctalIntegerLiteral

DecimalIntegerLiteral ::
    0
    NonZeroDigit DecimalDigits opt

DecimalDigits ::
    DecimalDigit
    DecimalDigits DecimalDigit

NonZeroDigit :: one of
```

1 2 3 4 5 6 7 8 9
HexIntegerLiteral ::
  0x HexDigit
  0X HexDigit
  HexIntegerLiteral HexDigit

HexDigit :: one of
  0 1 2 3 4 5 6 7 8 9 a b c d e f A B C D E F

OctalIntegerLiteral ::
  0 OctalDigit
  OctalLiteral OctalDigit

OctalDigit :: one of
  0 1 2 3 4 5 6 7

FloatingPointLiteral ::
  DecimalIntegerLiteral . DecimalDigits opt ExponentPart opt
  . DecimalDigits ExponentPart opt
  DecimalIntegerLiteral ExponentPart

ExponentPart ::
  ExponentIndicator SignedInteger

ExponentIndicator :: one of
e E

SignedInteger ::
  DecimalDigits
  + DecimalDigits
  – DecimalDigits

Semantics
A numeric literal stands for a value of the number type. This value is determined in two steps: first, a
mathematically accurate value (MV) is derived from the literal; second, this mathematical value (MV) is
rounded, using IEEE 754 round-to-nearest mode, to a representable value of the number type.

For any production A :: B whose with a single nonterminal on its right-hand side is a single nonterminal,
the MV of A is the MV of B.

• The MV of DecimalLiteral :: 0 is positive zero.
• The MV of DecimalLiteral :: NonZeroDigit Digits is (the MV of NonZeroDigit times 10^n) plus the
  MV of Digits, where n is the number of characters in Digits.
• The MV of DecimalDigits :: DecimalDigits DecimalDigit is (the MV of DecimalDigits times 10) plus
  the MV of DecimalDigit.
• The MV of DecimalDigit :: 0 or of HexDigit :: 0 or of OctalDigit :: 0 is positive zero.
• The MV of DecimalDigit :: 1 or of NonZeroDigit :: 1 or of HexDigit :: 1 or of OctalDigit :: 1 is 1.
• The MV of DecimalDigit :: 2 or of NonZeroDigit :: 2 or of HexDigit :: 2 or of OctalDigit :: 2 is 2.
• The MV of DecimalDigit :: 3 or of NonZeroDigit :: 3 or of HexDigit :: 3 or of OctalDigit :: 3 is 3.
• The MV of DecimalDigit :: 4 or of NonZeroDigit :: 4 or of HexDigit :: 4 or of OctalDigit :: 4 is 4.
• The MV of DecimalDigit :: 5 or of NonZeroDigit :: 5 or of HexDigit :: 5 or of OctalDigit :: 5 is 5.
• The MV of DecimalDigit :: 6 or of NonZeroDigit :: 6 or of HexDigit :: 6 or of OctalDigit :: 6 is 6.
• The MV of DecimalDigit :: 7 or of NonZeroDigit :: 7 or of HexDigit :: 7 or of OctalDigit :: 7 is 7.
• The MV of DecimalDigit :: 8 or of NonZeroDigit :: 8 or of HexDigit :: 8 or of OctalDigit :: 8 is 8.
• The MV of DecimalDigit :: 9 or of NonZeroDigit :: 9 or of HexDigit :: 9 or of OctalDigit :: 9 is 9.
• The MV of HexDigit :: a or of HexDigit :: A is 10.
• The MV of HexDigit :: b or of HexDigit :: B is 11.
• The MV of HexDigit :: c or of HexDigit :: C is 12.
• The MV of HexDigit :: d or of HexDigit :: D is 13.
• The MV of HexDigit :: e or of HexDigit :: E is 14.
• The MV of HexDigit :: f or of HexDigit :: F is 15.
• The MV of HexIntegerLiteral :: 0x HexDigit is the MV of HexDigit.
• The MV of HexIntegerLiteral :: 0X HexDigit is the MV of HexDigit.
• The MV of HexIntegerLiteral :: HexIntegerLiteral HexDigit is (the MV of HexIntegerLiteral times 16) plus the MV of HexDigit.
• The MV of OctalIntegerLiteral :: 0 OctalDigit is the MV of OctalDigit.
• The MV of OctalIntegerLiteral :: OctalIntegerLiteral OctalDigit is (the MV of OctalIntegerLiteral times 8) plus the MV of OctalDigit.
• The MV of FloatingPointLiteral :: DecimalIntegerLiteral . ExponentPart is the MV of DecimalIntegerLiteral times 10^e, where e is the MV of ExponentPart.
• The MV of FloatingPointLiteral :: DecimalIntegerLiteral . DecimalDigits ExponentPart is (the MV of DecimalIntegerLiteral plus (the MV of DecimalDigits times 10^n)), where n is the number of characters in DecimalDigits.
• The MV of FloatingPointLiteral :: DecimalDigits is the MV of DecimalDigits times 10^n, where n is the number of characters in DecimalDigits.
• The MV of FloatingPointLiteral :: DecimalDigits ExponentPart DecimalDigits is (the MV of DecimalDigits plus (the MV of DecimalDigits times 10^n)), where n is the number of characters in DecimalDigits.
• The MV of FloatingPointLiteral :: DecimalDigits ExponentPart DecimalDigits ExponentPart DecimalDigits is (the MV of DecimalDigits plus (the MV of DecimalDigits times 10^n)), where n is the number of characters in DecimalDigits.
• The MV of SignedInteger :: + DecimalDigits is the MV of DecimalDigits.
• The MV of SignedInteger :: - DecimalDigits is the negative of the MV of DecimalDigits.

Issue: this description, as it stands, does not take into account the resolution that only the first 19 significant digits or so need contribute to the calculated mathematical value. This still needs to be addressed. (It could be addressed in the grammar itself, but it would be too messy: a couple of hundred productions!)

3.7.4 String Literals
A string literal is zero or more characters enclosed in single or double quotes. Each character may be represented by an escape sequence.

Syntax

StringLiteral ::
    " DoubleStringCharacters_opt "
    \ SingleStringCharacters_opt 

DoubleStringCharacters ::
    DoubleStringCharacter DoubleStringCharacters_opt

SingleStringCharacters ::
    SingleStringCharacter SingleStringCharacters_opt
The definitions of the nonterminals HexDigit and OctalDigit are given in section 3.7.3.

Issue: Give a complete account of the interpretation of escape sequences.

The following table describes the set of character escape characters:

A string literal stands for a value of the String type. The string value (SV) of the literal is described in terms of character values (CV) contributed by the various parts of the string literal. As part of this process, some characters within the string literal are interpreted as having a mathematical value (MV), as described below or in section 3.7.3.
For any production $A \rightarrow B$ whose right-hand side is a single nonterminal, the SV of $A$ is the SV of $B$.

- The SV of `StringLiteral` :: " " is the empty character sequence.
- The SV of `StringLiteral` :: ' ' is the empty character sequence.
- The SV of `StringLiteral` :: " DoubleStringCharacters " is the SV of `DoubleStringCharacters`.
- The SV of `StringLiteral` :: ' SingleStringCharacters ' is the SV of `SingleStringCharacters`.
- The SV of `DoubleStringCharacters` :: `DoubleStringCharacter` is a sequence of one character, the CV of `DoubleStringCharacter`.
- The SV of `DoubleStringCharacters` :: `DoubleStringCharacter` DoubleStringCharacters is a sequence of the CV of `DoubleStringCharacter` followed by all the characters in the SV of `DoubleStringCharacters` in order.
- The SV of `SingleStringCharacters` :: `SingleStringCharacter` is a sequence of one character, the CV of `SingleStringCharacter`.
- The SV of `SingleStringCharacters` :: `SingleStringCharacter` SingleStringCharacters is a sequence of the CV of `SingleStringCharacter` followed by all the characters in the CV of `SingleStringCharacters` in order.
- The CV of `DoubleStringCharacter` :: SourceCharacter but not double-quote “or backslash \ or LineTerminator is the SourceCharacter character itself.
- The CV of `SingleStringCharacter` :: SourceCharacter but not double-quote “or backslash \ or LineTerminator is the SourceCharacter character itself.
- The CV of `CharacterEscapeSequence` :: \ SingleEscapeCharacter is the Unicode character whose Unicode value is determined by the SingleEscapeCharacter according to the following table:

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Unicode Value</th>
<th>Name</th>
<th>Symbolic Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>\b</td>
<td>\u0008</td>
<td>backspace</td>
<td>&lt;BS&gt;</td>
</tr>
<tr>
<td>\t</td>
<td>\u0009</td>
<td>horizontal</td>
<td>&lt;HT&gt;</td>
</tr>
<tr>
<td>\n</td>
<td>\u000A</td>
<td>line feed</td>
<td>&lt;LF&gt;</td>
</tr>
<tr>
<td>\f</td>
<td>\u000C</td>
<td>form feed</td>
<td>&lt;FF&gt;</td>
</tr>
<tr>
<td>\r</td>
<td>\u000D</td>
<td>carriage</td>
<td>&lt;CR&gt;</td>
</tr>
<tr>
<td>&quot;</td>
<td>\u0022</td>
<td>double quote</td>
<td>&quot;</td>
</tr>
<tr>
<td>'</td>
<td>\u0027</td>
<td>single quote'</td>
<td></td>
</tr>
<tr>
<td>\   \</td>
<td>\u005C</td>
<td>backslash</td>
<td>\</td>
</tr>
</tbody>
</table>
- The CV of `CharacterEscapeSequence` :: \ NonEscapeCharacter is the CV of the NonEscapeCharacter.
- The CV of `NonEscapeCharacter` :: SourceCharacter but not SingleEscapeCharacter or OctalDigit or x or u or LineTerminator is the SourceCharacter character itself.
- The CV of `HexEscapeSequence` :: \x HexDigit HexDigit is the Unicode character whose code is (16 times the MV of the first HexDigit) plus the MV of the second HexDigit.
- The CV of `OctalEscapeSequence` :: \ OctalDigit is the Unicode character whose code is the MV of the OctalDigit.
- The CV of `OctalEscapeSequence` :: \ OctalDigit OctalDigit is the Unicode character whose code is (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.
- The CV of `OctalEscapeSequence` :: \ ZeroToThree OctalDigit OctalDigit is the Unicode character whose code is (64 (that is, $8^2$) times the MV of the ZeroToThree) plus (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.
- The MV of ZeroToThree :: 0 is positive zero.
- The MV of ZeroToThree :: 1 is 1.
The MV of ZeroToThree:: 2 is 2.
The MV of ZeroToThree:: 3 is 3.
The CV of UnicodeEscapeSequence :: \u HexDigit HexDigit HexDigit HexDigit is the Unicode character whose code is (4096 (that is, $16^5$) times the MV of the first HexDigit) plus (256 (that is, $16^2$) times the MV of the second HexDigit) plus (16 times the MV of the third HexDigit) plus the MV of the fourth HexDigit.

Note that a LineTerminator character cannot appear in a string literal, even if preceded by a backslash \.
The correct way to cause a line terminator character to be part of the string value of a string literal is to use an escape sequence such as \n or \u000A.

### 3.8 Automatic Semicolon Insertion

**Description**

Certain ECMAScript statements (empty statement, variable statement, expression statement, continue statement, break statement, and return statement) must each be terminated with a semicolon. Such a semicolon may always appear explicitly in the source text. For convenience, however, such semicolons may be omitted from the source text in certain situations. We describe such situations by saying that semicolons are automatically inserted into the source code token stream in those situations:

- When, as the program is parsed from left to right, a token (called the *offending token*) is encountered that is not allowed by any production of the grammar and the parser is not currently parsing the header of a for statement, then a semicolon is automatically inserted before the offending token if one or more of the following conditions is true:
  1. The offending token is separated from the previous token by at least one LineTerminator.
  2. The offending token is EndOfSource.
  3. The offending token is }.

  However, there is an additional overriding condition: a semicolon is never inserted automatically if the semicolon would then be parsed as an empty statement.

- When, as the program is parsed from left to right, a token (called the *restricted token*) is encountered that is allowed by some production of the grammar, but the production is a restricted production and the restricted token is separated from the previous token by at least one LineTerminator, then there are two cases:
  4. If the parser is not currently parsing the header of a for statement, a semicolon is automatically inserted before the restricted token.
  5. If the parser is currently parsing the header of a for statement, it is a syntax error.

These are all the restricted productions in the grammar:

- ReturnStatement :
  
  return [no LineTerminator here] Expressionopt ;

- MemberExpression :
  
  MemberExpression [no LineTerminator here] IncrementOperator

- CallExpression :
  
  MemberExpression [no LineTerminator here] Arguments
  
  NewCallExpression [no LineTerminator here] Arguments
  
  CallExpression [no LineTerminator here] Arguments

The practical effect of these restricted productions is as follows:

1. When the token return is encountered and a LineTerminator is encountered before the next token is encountered, a semicolon is automatically inserted after the token return.
2. When the token `++` or `--` is encountered where the parser would treat it as a postfix operator, and at least one `LineTerminator` occurred between the preceding token and the `++` or `--` token, then a semicolon is automatically inserted before the `++` or `--` token.

3. When the token `{` is encountered where the parser would treat it as the first token of a parenthesized `Arguments` list, and at least one `LineTerminator` occurred between the preceding token and the `{` token, then a semicolon is automatically inserted before the `{` token.

The resulting practical advice to ECMAScript programmers is:

4. An `Expression` in a `return` statement should start on the same line as the `return` token.

5. A postfix `++` or `--` operator should appear on the same line as its operand.

6. The `{` that starts an argument list should be on the same line as the expression that indicates the function to be called.

For example, the source

```
{ 1 2 } 3<EOS>
```

is not a valid sentence in the ECMAScript grammar, even with the automatic semicolon insertion rules. In contrast, the source

```
{ 1
2 } 3<EOS>
```

is also not a valid ECMAScript sentence, but is transformed by automatic semicolon insertion into the following:

```
{ 1 ;2 ;} 3; <EOS>
```

which is a valid ECMAScript sentence.

The source

```
for (a; b
) <EOS>
```

is not a valid ECMAScript sentence and is not altered by automatic semicolon insertion because the place where a semicolon is needed is within the header of a `for` statement. Automatic semicolon insertion never occurs within the header of a `for` statement.

The source

```
return
a + b <EOS>
```

is transformed by automatic semicolon insertion into the following:

```
return;
a + b; <EOS>
```

Note that the expression `a + b` is not treated as a value to be returned by the `return` statement, because a `LineTerminator` separates it from the token `return`.

The source

```
a = b
++c <EOS>
```

is transformed by automatic semicolon insertion into the following:

```
a = b;
++c; <EOS>
```

Note that the token `++` is not treated as a postfix operator applying to the variable `b`, because a `LineTerminator` occurs between `b` and `++`.

The source

```
if (a > b)
else c = d <EOS>
```
is not a valid ECMAScript sentence and is not altered by automatic semicolon insertion before the `else`
token, even though no production of the grammar applies at that point, because an automatically inserted
semicolon would then be parsed as an empty statement.
4 Types

A value is an entity that takes on one of seven types. There are six standard types and one internal type called Reference. Values of type Reference are only used as intermediate results of expression evaluation and cannot be stored to properties of objects.

4.1 The Undefined Type

The Undefined type has exactly one value, called undefined. Any variable that has not been assigned a value is of type undefined.

4.2 The Null Type

The Null type has exactly one value, called null.

4.3 The Boolean Type

The Boolean type represents a logical entity and consists of exactly two unique values. One is called true and the other is called false.

4.4 The Number Type

The Number type has exactly \(2^{64} - 2^{53} + 3\) values, representing the double-precision 64-bit format IEEE 754 values as specified in the IEEE Standard for Binary Floating-Point Arithmetic, except that the \(2^{53} - 2\) distinct NaN values of the IEEE Standard are represented in ECMAScript as single special NaN value.

There are two other special values, called Positive Infinity and Negative Infinity. The other \(2^{64} - 2^{53} - 2\) values are called the finite numbers. Half of these are positive numbers and half are negative numbers; for every finite positive number there is a corresponding negative number having the same magnitude.

Note that there is both a positive zero and a negative zero.

The \(2^{64} - 2^{53} - 2\) finite nonzero values are of two kinds:

1. \(2^{64} - 2^{53} - 2\) finite nonzero values are of two kinds:
   - \(s \cdot m \cdot 2^e\), where \(s\) is +1 or −1, \(m\) is a positive integer less than 2^{53} but not less than 2^{52}, and \(e\) is an integer ranging from between −1074 to 971, inclusive.
   - \(s \cdot m \cdot 2^e\), where \(s\) is +1 or −1, \(m\) is a positive integer less than 2^{52}, and \(e\) is −1074.

Note that all the positive and negative integers whose magnitude is no greater than 2^{53} are representable in the Number type (indeed, the integer 0 has two representations, +0 and -0).

We say that a finite number has an odd significand if it is nonzero and the integer \(m\) used to express it (in one of the two forms shown above) is odd. Otherwise we say that it has an even significand.
In this specification, the phrase “the number value for \( x \)” where \( x \) represents an exact nonzero real mathematical quantity (which might even be an irrational number such as \( \pi \)) means a number value chosen in the following manner. Consider the set of all finite values of the Number type, with two additional values added to it that are not representable in the Number type, namely \( 2^{1024} \) (which is \( +1 \times 2^{53} \times 2^{971} \)) and \( -2^{1024} \) (which is \( -1 \times 2^{53} \times 2^{971} \)). Choose the member of this set that is closest in value to \( x \). If two values of the set are equally close, then the one with an even significand is chosen; for this purpose, the two extra values \( 2^{1024} \) and \( -2^{1024} \) are considered to have even significands. Finally, if \( 2^{1024} \) was chosen, replace it with positive infinity; if \( -2^{1024} \) was chosen, replace it with negative infinity; any other chosen value is used unchanged. The result is the number value for \( x \). (This procedure corresponds exactly to the behavior of the IEEE 754 “round to nearest” mode.)

Some ECMAScript operators deal only with integers in the range \(-2^{31} \) through \( 2^{31}-1 \), inclusive, or in the range 0 through \( 2^{32}-1 \), inclusive. These operators accept any value of the Number type but first convert each such value to one of \( 2^{32} \) integer values. See the descriptions of the ToInt32 and ToUint32 operators in sections 5.5 and ToUint32: (unsigned 32 bit integer)/ToUint32: (unsigned 32 bit integer) respectively.

## 4.5. The Object Type

An Object is an unordered collection of properties. Each property consists of a name, a value and a set of attributes.

### 4.5.1 Property Attributes

A property can have zero or more attributes from the following set:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ReadOnly</td>
<td>The property is a read-only property. Attempts to write to the property will be ignored.</td>
</tr>
<tr>
<td>ErrorOnWrite</td>
<td>This attribute has precedence over the ReadOnly attribute. Attempts to write to the property will result in a runtime error and the property will not be changed.</td>
</tr>
<tr>
<td>DontEnum</td>
<td>The property is not included in the for-in enumeration. See the description of the for-in statement in section The for..in Statement The for..in Statement.</td>
</tr>
<tr>
<td>DontDelete</td>
<td>Attempts to delete the property will be ignored. See the description of the delete operator in section The delete Operator The delete Operator.</td>
</tr>
<tr>
<td>Internal</td>
<td>Internal properties have no name and are not directly accessible via the property accessor operators. How these properties are accessed is implementation specific. How and when some of these properties are used is specified by the language specification.</td>
</tr>
</tbody>
</table>

### 4.5.2 Property Access

Internal properties and methods are not exposed in the language. For the purposes of this document, we give them names enclosed in double square brackets\([[]]\). When an algorithm uses an internal property of an object and the object does not implement the indicated internal property, a runtime error is generated.

There are two types of access for exposed properties: get and put, corresponding to retrieval and assignment.

Native ECMAScript objects have an internal property called \([[Prototype]]\). The value of this property is either null or an object and is used for implementing inheritance. Properties of the [[Prototype]] object are exposed as properties of the child object for the purposes of get access, but not for put access.

The following table summarizes the internal properties related to property access:

<table>
<thead>
<tr>
<th>Property</th>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Get]]</td>
<td>(PropertyName)</td>
<td>Returns the value of the property.</td>
</tr>
</tbody>
</table>
## 4.5.3 HasProperty

When the `[[HasProperty]]` method of `O` is called with property name `P`, the following steps are taken:

1. If `O` has a property with name `P`, return `true`.
2. If the `[[Prototype]]` of `O` is `null`, return `false`.
3. Call the `[[HasProperty]]` method of `[[Prototype]]` with property name `P`.
4. Return Result(3).

## 4.5.4 Get

When the `[[Get]]` method of `O` is called with property name `P`, the following steps are taken:

1. If `O` doesn’t have a property with name `P`, go to step 4.
2. Get the value of the property.
3. Return Result(2).
4. If the `[[Prototype]]` of `O` is `null`, return `undefined`.
5. Call the `[[Get]]` method of `[[Prototype]]` with property name `P`.
6. Return Result(5).

## 4.5.5 Put

To aid in defining the `[[Put]]` method, the `[[CanPut]]` method is first defined. As `[[CanPut]]` method is only used here (by the `[[Put]]` method with explicit access mode), it is not included in the table in 4.5.2.

When the `[[CanPut]]` method of `O` is called with property `P`, the following steps are taken:

1. If `O` doesn’t have a property with name `P`, go to step 4.
2. If the property has the ErrorOnWrite attribute, generate a runtime error.
3. If the property has the ReadOnly attribute, return false.
4. If the `[[Prototype]]` of `O` is `null`, return true.
5. Call the `[[CanPut]]` method of `[[Prototype]]` of `O` with property Name `P`.
6. Return Result(5).

When the `[[Put]]` method of `O` is called with property `P` and value `V`, the following steps are taken:

1. Call the `[[CanPut]]` method of `O` with name `P`.
2. If Result(1) is false, return.
3. If `O` doesn’t have a property with name `P`, go to step 6.
4. Set the value of the property to `V`.
5. Return.
6. Create a property with name `P`, set its value to `V` and give it empty attributes.
7. Return.

---

<table>
<thead>
<tr>
<th>Method</th>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[[Put]]</code> invention</td>
<td>(PropertyName, Value)</td>
<td>Sets the property to value.</td>
</tr>
<tr>
<td><code>[[Prototype]]</code> invention</td>
<td>None</td>
<td>Returns the parent object.</td>
</tr>
<tr>
<td><code>[[HasProperty]]</code> invention</td>
<td>(PropertyName)</td>
<td>Returns a boolean value indicating whether the object already has a member with the given name.</td>
</tr>
<tr>
<td><code>[[Construct]]</code> invention</td>
<td>Optional user provided parameters</td>
<td>(Constructor) Constructs an object. Invoked via the <code>new</code> operator.</td>
</tr>
<tr>
<td><code>[[Call]]</code> invention</td>
<td>Optional user provided parameters</td>
<td>(Function) Executes the object.</td>
</tr>
</tbody>
</table>
4.6 The String Type

The String type consists of the set of all finite sequences of zero or more Unicode characters.

Note: The concatenation operator (+), relational operators (<, >, <=, >=) and equality operators (==, !=) apply to this type.

4.7 The Internal Reference Type

The Internal Reference Type is not a language data type. Is it only defined here for the purposes of aiding this specification.

A Reference is a reference to an object’s property. A Reference consists of two parts, the base object and the property name.

In defining the semantics of ECMAScript, the following methods are defined for internal operations:

- GetBase(). Returns the base object component.
- GetPropertyName(). Returns the propertyName component.
- GetValue(). Returns the value of the indicated property.
- PutValue(). Sets the indicated property to the indicated value.

Values of type Reference are only used as intermediate results of expression evaluation and cannot be stored to properties of objects.

4.7.1 GetBase

1. If Type(V) is a Reference, return the base object component of V.
2. Generate a runtime error.

4.7.2 GetPropertyName

1. If Type(V) is a Reference, return the propertyName component of V.
2. Generate a runtime error.

4.7.3 GetValue

1. If Type(V) is not a Reference, return V.
2. Call GetBase(V).
3. If Result(2) is null, generate a runtime error.
4. Call the [[Get]] method of Result(2), passing GetPropertyName(V) for the property name.
5. Return Result(4).

4.7.4 PutValue

For values V and W, PutValue(V, W) performs:
1. If type (V) is not a Reference, generate a runtime error.
2. Call GetBase(V).
3. If Result(2) is null, go to step 6.
4. Call the [[Put]] method of Result(2), passing GetPropertyName(V) for the property name and W for the value.
5. Return.
6. Call the [[Put]] method for the global object, passing GetPropertyName(V) for the property name and W for the value.
7. Return.
5 Type Conversion

The ECMAScript runtime system performs automatic type conversion as needed. To clarify the semantics of certain constructs it is useful to define a set of conversion operators. These operators are not a part of the language; they are defined here to aid the specification of the semantics of the language. The conversion operators are polymorphic; that is, they can accept a value of any standard type, but not of type Reference.

5.1 ToPrimitive

The operator ToPrimitive takes a Value argument and an optional PreferredType argument. The operator ToPrimitive attempts to convert its value argument to a non-Object type. If an object is capable of converting to more than one primitive type, it may use the optional hint PreferredType to favor that type. Conversion occurs according to the following table:

<table>
<thead>
<tr>
<th>Input Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>Return the input argument (no conversion)</td>
</tr>
<tr>
<td>Null</td>
<td>Return the input argument (no conversion)</td>
</tr>
<tr>
<td>Boolean</td>
<td>Return the input argument (no conversion)</td>
</tr>
<tr>
<td>Number</td>
<td>Return the input argument (no conversion)</td>
</tr>
<tr>
<td>String</td>
<td>Return the input argument (no conversion)</td>
</tr>
<tr>
<td>Object</td>
<td>Return the default value of the Object. The default value of an object is retrieved by calling the internal [[DefaultValue]] method of the object passing an optional hint preferredType. The behavior of the [[DefaultValue]] method is defined by this specification for all native ECMAScript objects. If the return value is of type Object or Reference, a runtime error is generated.</td>
</tr>
</tbody>
</table>

5.2 ToBoolean

The operator ToBoolean attempts to convert its argument to a value of type Boolean according to the following table:

<table>
<thead>
<tr>
<th>Input Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>false</td>
</tr>
<tr>
<td>Null</td>
<td>false</td>
</tr>
<tr>
<td>Boolean</td>
<td>Return the input argument (no conversion)</td>
</tr>
</tbody>
</table>
| Number     | 0 ⇔ false  
            | NaN ⇔ false  
            | ≠ 0 and ≠ NaN ⇔ true |
String

= "" \(\Downarrow\) false (where "" denotes an empty string)
\neq "" \(\Downarrow\) true

Object

true

5.3 ToNumber

The operator ToNumber attempts to convert its argument to a value of type Number according to the following table:

<table>
<thead>
<tr>
<th>Input Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>NaN</td>
</tr>
<tr>
<td>Null</td>
<td>NaN</td>
</tr>
</tbody>
</table>
| Boolean    | true \(\Downarrow\) 1
false \(\Downarrow\) 0 |
| Number     | Return the input argument (no conversion) |
| String     | See grammar and discussion below. |
| Object     | Apply the following steps: \[\]
1. Call ToPrimitive(input argument, hint Number).
2. Call ToNumber(Result(1)).
3. Return Result(2). |

5.3.1 ToNumber Applied to the String Type

ToNumber applied to strings applies the following grammar to the input string. If the grammar cannot interpret the string then the result of ToNumber is NaN.

\[
\text{StringNumericLiteral ::= StrWhiteSpace_opt StrNumericLiteral StrWhiteSpace_opt}
\]

\[
\text{StrWhiteSpace ::= StrWhiteSpaceChar StrWhiteSpace_opt}
\]

\[
\text{StrWhiteSpaceChar ::= <TAB> SP FF VT CR LF}
\]

\[
\text{StrNumericLiteral ::= StrIntegerLiteral StrFloatingPointLiteral}
\]

\[
\text{StrIntegerLiteral ::= Sign_opt Digits_opt HexIntegerLiteral}
\]
HexIntegerLiteral :::
  0x HexDigit
  0X HexDigit

HexDigit ::: one of
  0 1 2 3 4 5 6 7 8 9 a b c d e f A B C D E F

StrFloatingPointLiteral :::
  Sign opt Digits . Digits opt ExponentPart opt
  Sign opt Digits ExponentPart opt
  Sign opt Digits ExponentPart

ExponentPart :::
  ExponentIndicator SignedInteger

ExponentIndicator ::: one of
  e E

SignedInteger :::
  Sign opt Digits

Sign ::: one of
  + -

5.4 ToInteger

The operator ToInteger attempts to convert its argument to an integral numeric value. This operator functions as follows:
1. Call ToNumber on the input argument.
2. If Result(1) is NaN, return 0 (positive zero).
3. If Result(1) is ±Infinity, return Result(1).
4. Compute sign(Result(1)) * floor(abs(Result(1))).
5. Return Result(4).

5.5 ToInt32: (signed 32 bit integer)

The operator ToInt32 converts its argument to one of $2^{32}$ integer values in the range $-2^{31}$ through $2^{31}-1$, inclusive. This operator functions as follows:
1. Call ToNumber on the input argument.
2. If Result(1) is NaN, Positive Infinity, or Negative Infinity, return 0 (positive zero).
3. Compute sign(Result(1)) * floor(abs(Result(1))).
4. If Result(3) is positive zero or negative zero, return 0 (positive zero).
5. Compute Result(3) modulo $2^{32}$; that is, a finite value $k$ of Number type with positive sign and less than $2^{32}$ in magnitude such the mathematical difference of Result(3) and $k$ is mathematically exactly divisible by $2^{32}$ when Result(3) is negative, compute the value of the expression $2^{32}-((1-Result(3)) \% 2^{32}) - 1$; otherwise compute Result(3) \% $2^{32}$.
6. If Result(5) is greater than or equal to $2^{31}$, return Result(5)-$2^{32}$; otherwise return Result(5).

Discussion:
Note that the ToInt32 operation is idempotent: if applied to a result that it produced, the second application leaves that value unchanged.
Note also that ToInt32(ToUint32(x)) is equal to ToInt32(x) for all values of x.
(It is to preserve this latter property that Positive Infinity and Negative Infinity are mapped to zero.)

5.6 ToUint32: (Unsigned 32 Bit Integer)
1. The operator ToUint32 converts its argument to one of 2^{32} integer values in the range 0 through 2^{32}-1, inclusive. This operator functions as follows: Call ToNumber on the input argument.
2. If Result(1) is NaN, Positive Infinity, or Negative Infinity, return 0 (positive zero).
3. Compute sign(Result(1)) * floor(abs(Result(1))).
4. If Result(3) is positive zero or negative zero, return 0 (positive zero).
5. Compute Result(3) modulo 2^{32}; that is, a finite value k of Number type with positive sign and less than 2^{32} in magnitude such the mathematical difference of Result(3) and k is mathematically exactly divisible by 2^{32}; if Result(3) is negative, compute the value of the expression 2^{32} - ((1-Result(3)) % 2^{32}) - 1; otherwise compute Result(3) % 2^{32}.
6. Return Result(5).

Discussion:
Note: Step 6 is the only difference between ToUint32 and ToInt32.
Note that the ToUint32 operation is idempotent: if applied to a result that it produced, the second application leaves that value unchanged.
Note also that ToUint32(ToInt32(x)) is equal to ToUint32(x) for all values of x.
(It is to preserve this latter property that Positive Infinity and Negative Infinity are mapped to zero.)

5.7 ToString
The operator ToString attempts to convert its argument to a value of type String according to the following table:

<table>
<thead>
<tr>
<th>Input Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>&quot;undefined&quot;</td>
</tr>
<tr>
<td>Null</td>
<td>&quot;null&quot;</td>
</tr>
<tr>
<td>Boolean</td>
<td>true \‡ &quot;true&quot;</td>
</tr>
<tr>
<td></td>
<td>false \‡ &quot;false&quot;</td>
</tr>
<tr>
<td>Number</td>
<td>See discussion below.</td>
</tr>
<tr>
<td>String</td>
<td>Return the input argument (no conversion)</td>
</tr>
<tr>
<td>Object</td>
<td>Apply the following steps:</td>
</tr>
<tr>
<td></td>
<td>1. Call ToPrimitive(input argument, hint String).</td>
</tr>
<tr>
<td></td>
<td>2. Call ToString(Result(1)).</td>
</tr>
<tr>
<td></td>
<td>3. Return Result(2).</td>
</tr>
</tbody>
</table>

5.7.1 ToString Applied to the Number Type

The operator ToString converts a number to string format as follows:

- If the argument is NaN, the result is the string "NaN".
- If the argument is positive zero or negative zero, the result is "0".
Otherwise, the result is a string that represents the sign and magnitude (absolute value) of the argument. If the sign is negative, the first character of the result is ‘-’; if the sign is positive, no sign character appears in the result. As for the magnitude $m$:

- If $m$ is infinity, it is represented by the characters "Infinity"; thus, positive infinity produces the result "Infinity" and negative infinity produces the result "-Infinity".
- If $m$ is zero, it is represented by the character '0'; thus, negative zero produces the result "-0" and positive zero produces the result "0".
- If $m$ is an integer less than $10^{216}$, then it is represented as that integer value in decimal form with no leading zeroes and no decimal point.
- If $m$ is greater than or equal to $10^{-63}$ but less than $10^{216}$, and is not an exact integer value, then it is represented as the integer part (floor) of $m$, in decimal form with no leading zeroes, followed by a decimal point ‘.’, followed by one or more decimal digits (see below) representing the fractional part of $m$.
- If $m$ is less than $10^{-63}$ or not less than $10^{216}$, then it is represented in so-called "computerized scientific notation." Let $n$ be the unique integer such that $10^n \leq m < 10^{n+1}$; then let $a$ be the mathematically exact quotient of $m$ and $10^n$ so that $1 \leq a < 10$. The magnitude is then represented as the integer part (floor) of $a$, as a single decimal digit, followed by a decimal point ‘.’, followed by one or more decimal digits (see below) representing the fractional part of $a$, followed by the letter ‘E’, followed by a representation of $n$ as a decimal integer (first a minus sign ‘-’ if $n$ is negative or nothing of $n$ is not negative, followed by the decimal representation of the magnitude of $n$ with no leading zeros).

How many digits must be printed for the fractional part of $m$ or $a$? There must be at least one digit; beyond that, there must be as many, but only as many, more digits as are needed to uniquely distinguish the argument value from all other representable numeric values. That is, suppose that $x$ is the exact mathematical value represented by the decimal representation produced by this method for a finite nonzero argument; then $d$ must be the value of number type nearest to $x$; or if two values of the Number type are equally close to $x$, then $d$ must be one of them and the least significant bit of $d$ must be 0. A consequence of this specification is that ToString never produces trailing zero digits for a fractional part.

Implementors of ECMAScript may find useful the paper and code written by David M. Gay for binary-to-decimal conversion of floating-point numbers [Gay 1990].

### 5.8 ToObject

The operator ToObject attempts to convert its argument to a value of type Object according to the following table:

<table>
<thead>
<tr>
<th>Input Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>generate a runtime error</td>
</tr>
<tr>
<td>Null</td>
<td>generate a runtime error</td>
</tr>
<tr>
<td>Boolean</td>
<td>Create a new Boolean object whose default value is the value of the boolean. See the Native ECMAScript Objects section for a description of the Boolean object.</td>
</tr>
<tr>
<td>Number</td>
<td>Create a new Number object whose default value is the value of the number. See the Native ECMAScript Objects section for a description of the Number object.</td>
</tr>
<tr>
<td>String</td>
<td>Create a new String object whose default value is the value of the string. See the Native ECMAScript Objects section for a description of the String object.</td>
</tr>
<tr>
<td>Object</td>
<td>Return the input argument (no conversion)</td>
</tr>
</tbody>
</table>
6 EXECUTION CONTEXTS

When control is transferred to ECMAScript executable code, we say that control is entering an execution context. Active execution contexts logically form a stack. The top execution context on this logical stack is the running execution context.

6.1 DEFINITIONS

6.1.1 Function Objects

There are four types of function objects:

- **Declared functions** are defined in source text by a `FunctionDeclaration`.
- **Anonymous functions** are created dynamically by using the built-in `Function` Object as a constructor which we refer to as instantiating `Function`.
- **Host functions** are created at the request of the host with source text supplied by the host. The mechanism for their creation is implementation dependent. Host functions may have any subset of the following attributes { ImplicitThis, ImplicitParents }. These attributes are described below.
- **Internal functions** are built-in objects of the language, such as `parseInt` and `Math.exp`. These functions do not contain executable code defined by the ECMAScript grammar, so are excluded from this discussion of execution contexts.

6.1.2 Types of Executable Code

There are five types of executable ECMAScript source text:

- **Global code** is source text that is outside all function declarations. More precisely, the global code of a particular ECMAScript `Program` consists of all `SourceElements` in the `Program` production which come from the `Statement` definition.
- **Eval code** is the source text supplied to the built-in `eval` function. More precisely, if the parameter to the built-in `eval` function is a string, it is treated as an ECMAScript `Program`. The eval code for a particular invocation of `eval` is the global code portion of the string parameter.
- **Function code** is source text that is inside a function declaration. More precisely, the function code of a particular ECMAScript `FunctionDeclaration` consists of the `Block` in the definition of `FunctionDeclaration`.
- **Anonymous code** is the source text supplied when instantiating `Function`. More precisely, the last parameter provided in an instantiation of `Function` is converted to a string and treated as the `StatementList` of the `Block` of a `FunctionDeclaration`. If more than one parameter is provided in an instantiation of `Function`, all parameters except the last one are converted to strings and concatenated together, separated by commas. The resulting string is interpreted as the `FormalParameterList` of a `FunctionDeclaration` for the `StatementList` defined by the last parameter.
- **Host code** is the source text supplied by the host when creating a host function. The source text is treated as the `StatementList` of the `Block` of a `FunctionDeclaration`. Depending on the implementation, the host may also supply a `FormalParameterList`. 
6.1.3 Variable Instantiation

Every execution context has associated with it a variable object. Variables declared in the source text are added as properties of the variable object. For global and eval code, functions defined in the source text are added as properties of the variable object. Function declarations in other types of code are not allowed by the grammar. For function, anonymous and host code, parameters are added as properties of the variable object. Which object is used as the variable object and what attributes are used for the properties depends on the type of code, but the remainder of the behavior is generic:

- For each FunctionDeclaration in the code, in source text order, instantiate a declared function from the FunctionDeclaration and create a property of the variable object whose name is the Identifier in the FunctionDeclaration, whose value is the declared function and whose attributes are determined by the type of code. If the variable object already has a property with this name, replace its value and attributes.
- For each formal parameter, as defined in the FormalParameterList, create a property of the variable object whose name is the Identifier and whose attributes are determined by the type of code. The values of the parameters are supplied by the caller. If the caller supplies fewer parameter values than there are formal parameters, the extra formal parameters have value undefined. If two or more formal parameters share the same name, hence the same property, the corresponding property is given the value that was supplied for the last parameter with this name. If the value of this last parameter was not supplied by the caller, the value of the corresponding property is undefined.
- For each VariableDeclaration in the code, create a property of the variable object whose name is the Identifier in VariableDeclaration, whose value is undefined and whose attributes are determined by the type of code. If there is already a property of the variable object with the name of a declared variable, the value of the property and its attributes are not changed. Semantically, this step must follow the creation of the FunctionDeclaration and FormalParameterList properties. In particular, if a declared variable has the same name as a declared function or formal parameter, the variable declaration does not disturb the existing property.

6.1.4 Scope Chain and Identifier Resolution

Every execution context has associated with it its own a scope chain. This is logically a list of objects that are searched when binding an Identifier. When control enters an execution context, the scope chain is created and is populated with an initial set of objects, depending on the type of code. When control leaves the execution context, the scope chain is destroyed.

During execution, the scope chain of the execution context is affected only by WithStatement. When execution enters a with block, the object specified in the with statement is added to the front of the scope chain. When execution leaves a with block, whether normally or via a break or continue statement, the object is removed from the scope chain. The object being removed will always be the first object in the scope chain.

During execution, the syntactic production PrimaryExpression : Identifier is evaluated using the following algorithm:

1. Get the next object in the scope chain. If there isn't one, go to step 5.
2. Call the [[HasProperty]] method of Result(l), passing the Identifier as the property.
3. If Result(2) is true, return a value of type Reference whose base object is Result(l), property name is the identifier.
4. Go to step 1.
5. Return a value of type Reference whose base object is null and whose property name is Identifier.

The result of binding an identifier is always a value of type Reference with its member name component equal to the identifier string.
6.1.5 Global Object

There is a unique global object which is created before control enters any execution context. Initially the
global object has the following properties:

- Built-in objects such as Math, String, Date, parseInt, etc. These have attributes { DontEnum }.
- Additional host defined properties. This may include a property whose value is the global object itself,
  for example window in HTML.

As control enters execution contexts, and as ECMAScript code is executed, additional properties may be
added to the global object and the initial properties may be changed.

6.1.6 Activation Object

When control enters an execution context for function code, anonymous code or host code, an object called
the activation object is created and associated with the execution context. The activation object is initialized
with a single property with name arguments and property attributes { DontDelete }. The initial value
of this property is the arguments object described below. The activation object is then used as the variable
object for the purposes of variable instantiation.

The activation object is purely a specification mechanism. It is impossible for an ECMAScript program to
access the activation object. It can access members of the activation object, but not the activation object
itself. When the call operation is applied to a Reference value whose base object is an activation object,
null is used as the this value of the call.

6.1.7 LabelStacks

The definitions of the control flow statements use two logical stacks, the break label stack and the continue
label stack. These are to facilitate the semantic definition of these statements and are not intended to imply a
particular implementation. Each execution context has its own label stacks, which are created and initialized
to empty when control enters the execution context. When control leaves the execution context, the label
stacks are destroyed.

6.1.8 This

There is a this value associated with every active execution context. The this value depends on the
caller and the type of code being executed and is determined when control enters the execution context. The
this value associated with an execution context is immutable.

6.1.9 Arguments Object

When control enters an execution context for function, anonymous or host code, an arguments object is
created and initialized as follows:

- A property is created with name callee and property attributes { DontEnum }. The initial value of
  this property is the function object being executed. This allows anonymous functions to be recursive.
- A property is created with name length and property attributes { DontEnum }. The initial value of
  this property is the number of actual parameter values supplied by the caller.
- For each non-negative integer, iarg, less than the value of the length property, a property is created
  with name ToString(iarg) and property attributes { DontEnum }. The initial value of this property is
  the value of the corresponding actual parameter supplied by the caller. The first actual parameter value
  corresponds to iarg = 0, the second to iarg = 1 and so on. In the case when iarg is less than the number
  of formal parameters for the function object, this property shares its value with the corresponding
  property of the activation object. This means that changing this property changes the corresponding
  property of the activation object and vice versa. The value sharing mechanism depends on the
  implementation.

Issue: Should the arguments object have a caller property?
6.2 ENTERING AN EXECUTION CONTEXT

When control enters an execution context, the scope chain is created and initialized, variable instantiation is performed, the break label and continue label stacks are created and initialized to empty, and the this value is determined.

The initialization of the scope chain, variable instantiation, and the determination of the this value depend on the type of code being entered.

6.2.1 Global Code

- The scope chain is created and initialized to contain the global object and no others.
- Variable instantiation is performed using the global object as the variable object and using empty property attributes.
- The this value is the global object.

6.2.2 EvalCode

When control enters an execution context for eval code, the previous active execution context, referred to as the calling context, is used to determine the scope chain, the variable object, and the this value. If there is no calling context, then initializing the scope chain, variable instantiation, and determination of the this value are performed just as for global code.

- The scope chain is initialized to contain the same objects, in the same order, as the calling context's scope chain. This includes objects added to the calling context's scope chain by WithStatement.
- Variable instantiation is performed using the calling context's variable object and using empty property attributes.
- The this value is the same as the this value of the calling context.

6.2.3 Function and Anonymous Code

- The scope chain is initialized to contain the activation object followed by the global object.
- Variable instantiation is performed using the activation object as the variable object and using property attributes { , DontDelete }.
- The caller provides the this value. If the this value provided by the caller is not an object (including the case where it is null), then the this value is the global object.

6.2.4 Host Code

- The scope chain is initialized to contain the activation object as its first element.
- If the host function has the ImplicitThis attribute, the this value is placed in the scope chain after the activation object.
- If the host function has the ImplicitParents attribute, a list of objects determined solely by the this value, is inserted in the scope chain after the activation object and this object. Note that this list is determined at runtime by the this value. It is not determined by any form of lexical scoping.
- The global object is placed in the scope chain after all other objects.
- Variable instantiation is performed using the activation object as the variable object and using attributes { DontEnum, DontDelete}
- The this value is determined just as for function and anonymous code.
7 EXPRESSIONS

7.1 PRIMARY EXPRESSIONS

Syntax

PrimaryExpression :
  this
  Identifier
  Literal
  ( Expression )

7.1.1 The this Keyword

The this keyword evaluates to the this value of the execution context.

7.1.2 Identifier Reference

An Identifier is evaluated using the scoping rules stated in section Scope Chain and Identifier Resolution. The result of an Identifier is always a value of type Reference.

7.1.3 Literal Reference

A Literal is evaluated as described in section Literals.

7.1.4 The Grouping Operator

The production PrimaryExpression : ( Expression ) is evaluated as follows:
1. Evaluate Expression. This may be of type Reference.
2. Return Result(1).

7.2 POSTFIX EXPRESSIONS

Syntax

MemberExpression :
  PrimaryExpression
  MemberExpression [ Expression ]
  MemberExpression . Identifier
  MemberExpression [ no LineTerminator here ] IncrementOperator
  new MemberExpression [ no LineTerminator here ] Arguments

IncrementOperator :
  ++
  --
The postfix increment operators and property accessor operators [ ] and . appear in both the MemberExpression and CallExpression productions. Generally we will refer to the productions involving MemberExpression with the understanding that the same remarks apply to CallExpression. Similarly, the CallExpression production includes three definitions involving the Arguments non-terminal. We will refer to the definition involving CallExpression.

7.2.1 Property Accessors

Properties are accessed by name, using either the dot notation MemberExpression . Identifier or the bracket notation MemberExpression [ Expression ].

The dot notation is transformed using the following syntactic conversion:

MemberExpression . Identifier

is exactly equivalent to:

MemberExpression [ <identifier-string> ]

where <identifier-string> is a string literal containing the same sequence of characters as the identifier.

The production MemberExpression : MemberExpression [ Expression ] is evaluated as follows:

1. Evaluate MemberExpression.
2. Call GetValue(Result(1)).
3. Evaluate Expression.
4. Call GetValue(Result(3)).
5. Call ToObject(Result(2)).
6. Call ToString(Result(4)).
7. Return a value of type Reference whose base object is Result(5), member name is Result(6) and access mode is explicit.
7.2.2 Postfix Increment and Decrement Operators

The production $\text{MemberExpression} : \text{MemberExpression IncrementOperator}$ is evaluated as follows:
1. Evaluate MemberExpression.
2. Call GetValue(Result(1)).
3. Call ToNumber(Result(2)).
4. For $++$, Result(4) is Result(3) increased by one. For $--$, Result(4) is Result(3) decreased by one. In either case, if Result(3) is NaN or $-\infty$, Result(4) is the same as Result(3).
5. Call PutValue(Result(1), Result(4)).

7.2.3 The $\text{new}$ Operator

The production $\text{NewExpression} : \text{new MemberExpression}$ is evaluated as follows:
1. Evaluate MemberExpression.
2. Call GetValue(Result(1)).
3. If Type(Result(2)) is not Object, generate a runtime error.
4. If Result(2) does not implement the internal $\text{[[Construct]]}$ method, generate a runtime error.
5. Call the $\text{[[Construct]]}$ method on Result(2), providing no arguments (that is, an empty list of arguments).
6. If Type(Result(5)) is not Object, generate a runtime error.
7. Return Result(5).

The production $\text{newCallExpression} : \text{new MemberExpression Arguments}$ is evaluated as follows:
1. Evaluate MemberExpression.
2. Call GetValue(Result(1)).
3. For each AssignmentExpression in ArgumentList, in left to right order, evaluate AssignmentExpression and call GetValue on the result. Keep all of these values in an internal list.
4. If Type(Result(2)) is not Object, generate a runtime error.
5. If Result(2) does not implement the internal $\text{[[Construct]]}$ method, generate a runtime error.
6. Call the $\text{[[Construct]]}$ method on Result(2), providing the list generated in step 3 as the parameters.
7. If Type(Result(6)) is not Object, generate a runtime error.
8. Return Result(6).

7.2.4 Function Calls

The production $\text{CallExpression} : \text{CallExpression Arguments}$ is evaluated as follows:
1. Evaluate CallExpression.
2. For each AssignmentExpression in ArgumentList, in left to right order, evaluate AssignmentExpression and call GetValue on the result. Keep all of these values in an internal list.
3. Call GetValue(Result(1)).
4. If Type(Result(3)) is not Object, generate a runtime error.
5. If Result(3) does not implement the internal $\text{[[Call]]}$ method, generate a runtime error.
6. If Type(Result(1)) is Reference, Result(6) is GetBase(Result(1)). Otherwise, Result(6) is null.
7. If Result(6) is an activation object, Result(7) is null. Otherwise, Result(7) is the same as Result(6).
8. Call the $\text{[[Call]]}$ method on Result(3), providing Result(7) as the this value and providing the list generated in step 2 as the parameters.
9. Return Result(8).

Note: Result(8) will never be of type Reference for native ECMAScript objects. Whether an external object can return a value of type Reference is implementation dependent.
7.3 Unary Operators

Syntax

UnaryExpression :
    PostfixExpression

    delete UnaryExpression
    void UnaryExpression
    typeof UnaryExpression
    IncrementOperator UnaryExpression
    + UnaryExpression
    - UnaryExpression
    ~ UnaryExpression
    ! UnaryExpression

7.3.1 The delete Operator

The production UnaryExpression : delete UnaryExpression is evaluated as follows:
1. Evaluate UnaryExpression.
2. Call GetBase(Result(1)).
3. Call GetPropertyName(Result(1)).
4. If Type(Result(2)) is not Object, return true.
5. If Result(2) does not implement the internal [[Delete]] method, go to step 8.
6. Call the [[Delete]] method on Result(2), providing Result(3) as the property name to delete.
7. Return Result(6).
8. Call the [[HasProperty]] method on Result(2), providing Result(3) as the property name to check for.
9. If Result(8) is true, return false.
10. Return true.

7.3.2 The void Operator

The production UnaryExpression : void UnaryExpression is evaluated as follows:
1. Evaluate UnaryExpression.
2. Call GetValue(Result(1)).
3. Return undefined.

7.3.3 The typeof Operator

The production UnaryExpression : typeof UnaryExpression is evaluated as follows:
1. Evaluate UnaryExpression.
2. If Type(Result(1)) is Reference and GetBase(Result(1)) is null, return "undefined".
3. Call GetValue(Result(1)).
4. Return a string determined by Type(Result(3)) according to the following table:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Type</td>
</tr>
<tr>
<td>2.</td>
<td>Undefined</td>
</tr>
<tr>
<td>3.</td>
<td>Null</td>
</tr>
<tr>
<td>4.</td>
<td>Boolean</td>
</tr>
<tr>
<td>5.</td>
<td>Number</td>
</tr>
<tr>
<td>6.</td>
<td>String</td>
</tr>
<tr>
<td>7.</td>
<td>Object (native and doesn’t implement)</td>
</tr>
</tbody>
</table>
7.3.4 Prefix Increment and Decrement Operators

The production `UnaryExpression : IncrementOperator UnaryExpression` is evaluated as follows:
1. Evaluate UnaryExpression.
2. Call GetValue(Result(1)).
3. Call ToNumber(Result(2)).
4. For `++`, `Result(4)` is `Result(3)` increased by one. For `--`, `Result(4)` is `Result(3)` decreased by one. In either case, if `Result(3)` is NaN or \(-\infty\), `Result(4)` is the same as `Result(3)`.
5. Call PutValue(Result(1), Result(4)).

7.3.5 Unary + and − Operators

The production `UnaryExpression : + UnaryExpression` is evaluated as follows:
1. Evaluate UnaryExpression.
2. Call GetValue(Result(1)).
3. Call ToNumber(Result(2)).
4. Return Result(3).

The production `UnaryExpression : - UnaryExpression` is evaluated as follows:
1. Evaluate UnaryExpression.
2. Call GetValue(Result(1)).
3. Call ToNumber(Result(2)).
4. If Result(3) is NaN, return NaN.
5. Negate Result(3).
6. Return Result(5).

7.3.6 The Bitwise NOT Operator ( ~ )

The production `UnaryExpression : ~ UnaryExpression` is evaluated as follows:
1. Evaluate UnaryExpression.
2. Call GetValue(Result(1)).
3. Call ToInt32(Result(2)).
4. Apply bitwise complement to Result(3). The result is a signed 32-bit integer.
5. Return Result(4).

7.3.7 Logical NOT Operator ( ! )

The production `UnaryExpression : ! UnaryExpression` is evaluated as follows:
1. Evaluate UnaryExpression.
2. Call GetValue(Result(1)).
3. Call ToBoolean(Result(2)).
4. If Result(3) is true, return false.
5. Return true.
7.4 Multiplicative Operators

Syntax

\[
\text{MultiplicativeExpression : }
\text{UnaryExpression}\]
\[
\text{MultiplicativeExpression } \ast \text{ UnaryExpression}
\]
\[
\text{MultiplicativeExpression } / \text{ UnaryExpression}
\]
\[
\text{MultiplicativeExpression } \% \text{ UnaryExpression}
\]

Semantics

The production \text{MultiplicativeExpression : MultiplicativeExpression } \ast \text{ UnaryExpression}, where \ast stands for one of the operators in the above definitions, is evaluated as follows:

1. Evaluate MultiplicativeExpression.
2. Call GetValue(Result(1)).
3. Evaluate UnaryExpression.
4. Call GetValue(Result(3)).
5. Call ToNumber(Result(2)).
6. Call ToNumber(Result(4)).
7. Apply the specified operation (\ast, /, or \%) to Result(5) and Result(6). See the discussions below (7.4.1, 7.4.2, 7.4.3).
8. Return Result(7).

7.4.1 Applying the \ast Operator

The \ast operator performs multiplication, producing the product of its operands. Multiplication is commutative. Multiplication is not always associative in ECMAScript, because of finite precision. The result of a floating-point multiplication is governed by the rules of IEEE 754 double-precision arithmetic:

- If either operand is NaN, the result is NaN.
- The sign of the result is positive if both operands have the same sign, negative if the operands have different signs.
- Multiplication of an infinity by a zero results in NaN.
- Multiplication of an infinity by an infinity results in an infinity. The sign is determined by the rule already stated above.
- Multiplication of an infinity by a finite non-zero value results in a signed infinity. The sign is determined by the rule already stated above.
- In the remaining cases, where neither an infinity or NaN is involved, the product is computed and rounded to the nearest representable value using IEEE 754 round-to-nearest mode. If the magnitude is too large to represent, the result is then an infinity of appropriate sign. If the magnitude is too small to represent, the result is then a zero of appropriate sign. The ECMAScript language requires support of gradual underflow as defined by IEEE 754.

7.4.2 Applying the / Operator

The / operator performs division, producing the quotient of its operands. The left operand is the dividend and the right operand is the divisor. ECMAScript does not perform integer division. The operands and result of all division operations are double-precision floating-point numbers. The result of division is determined by the specification of IEEE 754 arithmetic:

- If either operand is NaN, the result is NaN.
- The sign of the result is positive if both operands have the same sign, negative if the operands have different signs.
• Division of an infinity by an infinity results in NaN.

• Division of an infinity by a zero results in an infinity. The sign is determined by the rule already stated above.

• Division of an infinity by a non-zero finite value results in a signed infinity. The sign is determined by the rule already stated above.

• Division of a finite value by an infinity results in zero.

• Division of a zero by a zero results in NaN; division of zero by any other finite value results in zero.

• Division of a non-zero finite value by a zero results in a signed infinity. The sign is determined by the rule already stated above.

• In the remaining cases, where neither an infinity, nor a zero, nor NaN is involved, the quotient is computed and rounded to the nearest representable value using IEEE 754 round-to-nearest mode. If the magnitude is too large to represent, we say the operation overflows; the result is then an infinity of appropriate sign. If the magnitude is too small to represent, we say the operation underflows and the result is zero. The ECMAScript language requires support of gradual underflow as defined by IEEE 754.

7.4.1 Applying the % Operator

The binary % operator is said to yield the remainder of its operands from an implied division; the left operand is the dividend and the right operand is the divisor. In C and C++, the remainder operator accepts only integral operands, but in ECMAScript, it also accepts floating-point operands.

The result of a floating-point remainder operation as computed by the % operator is not the same as the "remainder" operation defined by IEEE 754. The IEEE 754 "remainder" operation computes the remainder from a rounding division, not a truncating division, and so its behavior is not analogous to that of the usual integer remainder operator. Instead the ECMAScript language defines % on floating-point operations to behave in a manner analogous to that of the Java integer remainder operator; this may be compared with the C library function fmod.

The result of a ECMAScript floating-point remainder operation is determined by the rules of IEEE arithmetic:

• If either operand is NaN, the result is NaN.

• The sign of the result equals the sign of the dividend.

• If the dividend is an infinity, or the divisor is a zero, or both, the result is NaN.

• If the dividend is finite and the divisor is an infinity, the result equals the dividend.

• If the dividend is a zero and the divisor is finite, the result is the same as the dividend zero.

• In the remaining cases, where neither an infinity, nor a zero, nor NaN is involved, the floating-point remainder r from a dividend n and a divisor d is defined by the mathematical relation r = n - (d * q) where q is an integer that is negative only if n/d is negative and positive only if n/d is positive, and whose magnitude is as large as possible without exceeding the magnitude of the true mathematical quotient of n and d.

7.5 Additive Operators

Syntax

AdditiveExpression : 
    MultiplicativeExpression
    AdditiveExpression + MultiplicativeExpression
    AdditiveExpression - MultiplicativeExpression
7.5.1 The Addition Operator ( + )

The addition operator either performs string concatenation or numeric addition.

The production $AdditiveExpression : AdditiveExpression + MultiplicativeExpression$ is evaluated as follows:
1. Evaluate AdditiveExpression.
2. Call GetValue(Result(1)).
3. Evaluate MultiplicativeExpression.
4. Call GetValue(Result(3)).
5. Call ToPrimitive(Result(2), hint Number).
6. Call ToPrimitive(Result(4), hint Number).
7. If Type(Result(5)) is String or Type(Result(6)) is String, go to step 13. (Note that this step differs from step 7 in the algorithm for the relational operators in using or instead of and.)
8. Call ToNumber(Result(5)).
9. Call ToNumber(Result(6)).
10. If Result(8) or Result(9) is NaN, return NaN.
11. Apply the addition operation to Result(8) and Result(9). See the discussion below.
12. Return Result(11).
13. Call ToString(Result(5)).
14. Call ToString(Result(6)).
15. Concatenate Result(13) followed by Result(14).

7.5.1 The Subtraction Operator ( − )

The production $AdditiveExpression : AdditiveExpression - MultiplicativeExpression$ is evaluated as follows:
1. Evaluate AdditiveExpression.
2. Call GetValue(Result(1)).
3. Evaluate MultiplicativeExpression.
4. Call GetValue(Result(3)).
5. Call ToNumber(Result(2)).
6. Call ToNumber(Result(4)).
7. Apply the subtraction operation to Result(5) and Result(6). See the discussion below (7.5.3).
8. Return Result(7).

7.5.3 Applying the Additive Operators (+, −)

The + operator performs addition when applied to two operands of numeric type, producing the sum of the operands. The − operator performs subtraction, producing the difference of two numeric operands. Addition is a commutative operation, but not always associative.

The result of an addition is determined using the rules of IEEE 754 double-precision arithmetic:
- If either operand is NaN, the result is NaN.
- The sum of two infinities of opposite sign is NaN.
- The sum of two infinities of the same sign is the infinity of that sign.
- The sum of an infinity and a finite value is equal to the infinite operand.
- The sum of two negative zeros is negative zero. The sum of two positive zeros, or of two zeros of opposite sign, is positive zero.
- The sum of a zero and a nonzero finite value is equal to the nonzero operand.
- The sum of two nonzero finite values of the same magnitude and opposite sign is positive zero.
In the remaining cases, where neither an infinity, nor a zero, nor NaN is involved, and the operands have the same sign or have different magnitudes, the sum is computed and rounded to the nearest representable value using IEEE 754 round-to-nearest mode. If the magnitude is too large to represent, the operation overflows and the result is then an infinity of appropriate sign. If the magnitude is too small to represent, the operation underflows and the result is zero. The ECMAScript language requires support of gradual underflow as defined by IEEE 754.

The − operator performs subtraction when applied to two operands of numeric type producing the difference of its operands; the left operand is the minuend and the right operand is the subtrahend. Given numeric operands a and b, it is always the case that a − b produces the same result as a + (−b).

### 7.6 Bitwise Shift Operators

#### Syntax

\[
\text{ShiftExpression} : \\
\text{AdditiveExpression} \\
\text{ShiftExpression} << \text{AdditiveExpression} \\
\text{ShiftExpression} >> \text{AdditiveExpression} \\
\text{ShiftExpression} >>> \text{AdditiveExpression}
\]

#### Discussion

The result of evaluating \( \text{ShiftExpression} \) is always truncated to 32 bits. If the result of evaluating \( \text{ShiftExpression} \) produces a fractional component, the fractional component is discarded. The result of evaluating \( \text{AdditiveExpression} \) is always truncated to five bits.

#### 7.6.1 The Left Shift Operator ( \( << \) )

Performs a bitwise left shift operation on the left argument by the amount specified by the right argument. The production \( \text{ShiftExpression} \) : \( \text{ShiftExpression} << \text{AdditiveExpression} \) is evaluated as follows:

1. Evaluate \( \text{ShiftExpression} \).
2. Call GetValue(Result(1)).
3. Evaluate \( \text{AdditiveExpression} \).
4. Call GetValue(Result(3)).
5. Call ToInt32(Result(2)).
6. Call ToInt32(Result(4)).
7. Mask out all but the least significant 5 bits of Result(6), that is, compute Result(6) & 0x1F.
8. Left shift Result(5) by Result(7) bits. The result is a signed 32 bit integer.
9. Return Result(8).

#### 7.6.2 The Signed Right Shift Operator ( \( >> \) )

Performs a sign-filling bitwise right shift operation on the left argument by the amount specified by the right argument. The production \( \text{ShiftExpression} \) : \( \text{ShiftExpression} >> \text{AdditiveExpression} \) is evaluated as follows:

1. Evaluate \( \text{ShiftExpression} \).
2. Call GetValue(Result(1)).
3. Evaluate \( \text{AdditiveExpression} \).
4. Call GetValue(Result(3)).
5. Call ToInt32(Result(2)).
6. Call ToInt32(Result(4)).
7. Mask out all but the least significant 5 bits of Result(6), that is, compute Result(6) & 0x1F.
8. Perform sign-extending right shift of Result(5) by Result(7) bits. The most significant bit is propagated. The result is a signed 32 bit integer.
7.6.3 The Unsigned Right Shift Operator ( 

Performs a zero-filling bitwise right shift operation on the left argument by the amount specified by the right argument.

The production \textit{ShiftExpression} : \textit{ShiftExpression} \texttt{>>>} \textit{AdditiveExpression} is evaluated as follows:

1. Evaluate \textit{ShiftExpression}.
2. Call \texttt{GetValue(}Result(1))\texttt{).}
3. Evaluate \textit{AdditiveExpression}.
4. Call \texttt{GetValue(}Result(3))\texttt{).}
5. Call \texttt{ToUint32(}Result(2))\texttt{).}
6. Call \texttt{ToInt32(}Result(4))\texttt{).}
7. Mask out all but the least significant 5 bits of Result(6), that is, compute Result(6) & 0x1F.
8. Perform zero-filling right shift of Result(5) by Result(7) bits. Vacated bits are filled with zero. The result is an unsigned 32 bit integer.
9. Return Result(8).

7.7 RELATIONAL OPERATORS

Syntax

\textit{RelationalExpression} :
\textit{ShiftExpression} \texttt{@} \textit{ShiftExpression}
\textit{RelationalExpression} \texttt{<} \textit{ShiftExpression}
\textit{RelationalExpression} \texttt{>} \textit{ShiftExpression}
\textit{RelationalExpression} \texttt{<=} \textit{ShiftExpression}
\textit{RelationalExpression} \texttt{>=} \textit{ShiftExpression}

Semantics

In the discussion below, the following special operators will be used:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric@</td>
<td>Where @ represents one of the relational operators. The operands are of type Number. This is the standard IEEE operator with the provision that if either operand is NaN, the result is false.</td>
</tr>
<tr>
<td>Character@</td>
<td>Where @ represents one of the relational operators. The operands are of type String. The operands are compared character by character lexicographically in the unicode character set. If the operands are of different length and all corresponding characters up to the length of the shorter operand are the same, the longer string is considered to be greater.</td>
</tr>
</tbody>
</table>

The production \textit{RelationalExpression} : \textit{RelationalExpression} \texttt{@} \textit{ShiftExpression}, where @ represents one of the relational operators, is evaluated as follows:

1. Evaluate \textit{RelationalExpression}.
2. Call \texttt{GetValue(}Result(1))\texttt{).}
3. Evaluate \textit{ShiftExpression}.
4. Call \texttt{GetValue(}Result(3))\texttt{).}
5. Call \texttt{ToPrimitive(}Result(2), hint Number)\texttt{).}
6. Call \texttt{ToPrimitive(}Result(4), hint Number)\texttt{).}
7. If Type(}Result(5)) is String and Type(}Result(6)) is String, go to step 1243. (Note that this step differs from step 7 in the algorithm for the addition operator + in using and instead of or.)
8. Call \texttt{ToNumber(}Result(5))\texttt{).}
9. Call ToNumber(Result(6)).
10. Apply Numeric@ to Result(8) and Result(9).
11. Return Result(10).
12. Call ToString(Result(5)).
12. Call ToString(Result(6)).
12. Apply Character@ to Result(5) and Result(6).
13. Return Result(12).

7.8 Equality Operators

Syntax

EqualityExpression :
  RelationalExpression
  EqualityExpression == RelationalExpression
  EqualityExpression != RelationalExpression

The production EqualityExpression : EqualityExpression == RelationalExpression is evaluated as follows:
1. Evaluate EqualityExpression.
2. Call GetValue(Result(1)).
3. Evaluate RelationalExpression.
4. Call GetValue(Result(3)).
5. If Type(Result(2)) is different from Type(Result(4)), go to step 12.
6. If Type(Result(2)) is Undefined, return true.
7. If Type(Result(2)) is Null, return true.
8. If Type(Result(2)) is Number, apply Numeric== to Result(2) and Result(4) and return the result.
9. If Type(Result(2)) is String, apply Character== to Result(2) and Result(4) and return the result.
10. If Type(Result(2)) is Boolean, return true when Result(2) and Result(4) are both true or both false.
    Otherwise, return false.
11. Return true if Result(2) and Result(4) refer to the same object. Otherwise, return false.
12. If Result(2) is null and Result(4) is undefined, return true.
13. If Result(2) is undefined and Result(4) is null, return true.
14. If Type(Result(2)) is Number and Type(Result(4)) is String, return the result of the comparison
    ToString(Result(2)) == Result(4).
15. If Type(Result(2)) is String and Type(Result(4)) is Number, return the result of the comparison
    Result(2) == ToString(Result(4)).
16. Return false.

The production EqualityExpression : EqualityExpression != RelationalExpression is evaluated as follows:
1. Evaluate the production EqualityExpression == RelationalExpression.
2. If Result(1) is true, return false.
3. Return true.

Discussion

String comparison can be forced by: "a + b == "a + b."
Numeric comparison can be forced by: a - 0 == b - 0.
Boolean comparison can be forced by: !a == !b.
The equality operators maintain the following invariants:
1. A != B is equivalent to !(A == B).
2. A == B is equivalent to B == A, except in the order of evaluation of A and B.
3. if A == B and B == C, => A == C, assuming no side effects.
As no conversions are applied to the operands, equality is always transitive.

### 7.9 Binary Bitwise Operators

**Syntax**

\[
\text{BitwiseANDExpression} : \\
\quad \text{EqualityExpression} \\
\quad \text{BitwiseANDExpression} \& \text{EqualityExpression}
\]

\[
\text{BitwiseXORExpression} : \\
\quad \text{BitwiseANDExpression} \\
\quad \text{BitwiseXORExpression} \^ \text{BitwiseANDExpression}
\]

\[
\text{BitwiseORExpression} : \\
\quad \text{BitwiseXORExpression} \\
\quad \text{BitwiseORExpression} \mid \text{BitwiseXORExpression}
\]

**Semantics**

The production \( A : A @ B \), where @ is one of the bitwise operators in the productions above, is evaluated as follows:

1. Evaluate \( A \).
2. Call GetValue(Result(1)).
3. Evaluate \( B \).
4. Call GetValue(Result(3)).
5. Call ToInt32(Result(2)).
6. Call ToInt32(Result(4)).
7. Apply the bitwise operator @ to Result(5) and Result(6). The result is a signed 32 bit integer.
8. Return Result(7).

### 7.10 Binary Logical Operators

**Syntax**

\[
\text{LogicalANDExpression} : \\
\quad \text{BitwiseORExpression} \\
\quad \text{LogicalANDExpression} \&\& \text{BitwiseORExpression}
\]

\[
\text{LogicalORExpression} : \\
\quad \text{LogicalANDExpression} \\
\quad \text{LogicalORExpression} \mid\mid \text{LogicalANDExpression}
\]

**Semantics**

The production \( \text{LogicalANDExpression} : \text{LogicalANDExpression} \&\& \text{BitwiseORExpression} \) is evaluated as follows:

1. Evaluate \( \text{LogicalANDExpression} \).
2. Call GetValue(Result(1)).
3. Call ToBoolean(Result(2)).
4. If Result(3) is false, return Result(2).
5. Evaluate \( \text{BitwiseORExpression} \).
6. Call GetValue(Result(5)).
7. Return Result(6).
The production \textit{LogicalORExpression} : \textit{LogicalORExpression} \texttt{||} \textit{LogicalANDExpression} is evaluated as follows:
1. Evaluate \textit{LogicalORExpression}.
2. Call \texttt{GetValue(Result(1))}.
3. Call \texttt{ToBoolean(Result(2))}.
4. If Result(3) is true, return Result(2).  
5. Evaluate \textit{LogicalANDExpression}.
6. Call \texttt{GetValue(Result(5))}.
7. Return Result(6).

\textbf{7.11 Conditional Operator ( ? : )}

\textbf{Syntax}

\texttt{ConditionalExpression} :
\textit{LogicalORExpression} \textit{LogicalORExpression} ? \textit{AssignmentExpression} : \textit{AssignmentExpression}

\textbf{Semantics}

The production \textit{ConditionalExpression} : \textit{LogicalORExpression} ? \textit{AssignmentExpression} : \textit{AssignmentExpression} is evaluated as follows:
1. Evaluate \textit{LogicalORExpression}.
2. Call \texttt{GetValue(Result(1))}.
3. Call \texttt{ToBoolean(Result(2))}.
4. If Result(3) is false, go to step 8.
5. Evaluate the first \textit{AssignmentExpression}.
6. Call \texttt{GetValue(Result(5))}.
7. Return Result(6).
8. Evaluate the second \textit{AssignmentExpression}.
9. Call \texttt{GetValue(Result(8))}.
10. Return Result(9).

Issue: Add an explanation of how the grammar differs slightly from that of C and Java here.

\textbf{7.12 Assignment Operators}

\textbf{Syntax}

\texttt{AssignmentExpression} :
\textit{ConditionalExpression}
\textit{PostfixUnaryExpression AssignmentOperator AssignmentExpression}

\textit{AssignmentOperator} :: one of
\begin{itemize}
\item \texttt{=} \ texttt{*= /= %=} \texttt{+= -= <<= >>= >>>=} \texttt{&=} \texttt{^=} \texttt{|=}
\end{itemize}

\textbf{7.12.1 Simple Assignment ( = )}

The production \textit{AssignmentExpression} : \textit{PostfixUnaryExpression} = \textit{AssignmentExpression} is evaluated as follows:
1. Evaluate \textit{PostfixUnaryExpression}.
2. Evaluate \textit{AssignmentExpression}.
3. Call \texttt{GetValue(Result(2))}.
4. Call \texttt{PutValue(Result(1), Result(3))}.
5. Return Result(3).
7.12.2 Compound Assignment ( \( \mathsf{op=} \) )

The production \( \text{AssignmentExpression} : \text{PostfixUnaryExpression} \mathsf{op} = \text{AssignmentExpression} \), where \( \mathsf{op} \) represents one of operators indicated above, is evaluated as follows:
1. Evaluate \( \text{PostfixUnaryExpression} \).
2. Call GetValue(Result(1)).
3. Evaluate AssignmentExpression.
4. Call GetValue(Result(2)).
5. Apply operator \( \mathsf{op} \) to Result(3) and Result(4).
6. Call PutValue(Result(1), Result(5)).
7. Return Result(5).

7.13 Comma Operator ( , )

Syntax

\[
\text{Expression} : \\
\text{AssignmentExpression} \\
\text{Expression} , \text{AssignmentExpression}
\]

Semantics

The production \( \text{Expression} : \text{Expression} , \text{AssignmentExpression} \) is evaluated as follows:
1. Evaluate Expression.
2. Call GetValue(Result(1)).
3. Evaluate AssignmentExpression.
4. Call GetValue(Result(3)).
5. Return Result(4).
8 STATEMENTS

Syntax

Statement :
  Block
  VariableStatement
  EmptyStatement
  ExpressionStatement
  IfStatement
  IterationStatement
  ContinueStatement
  BreakStatement
  ReturnStatement
  WithStatement

Block :
  { StatementListopt }

StatementList :
  Statement
  StatementList Statement

Semantics

The production StatementList : StatementList Statement is evaluated as follows:
1. Evaluate StatementList.
2. Evaluate Statement.

8.1 VARIABLE STATEMENT

Syntax

VariableStatement :
  var VariableDeclarationList ;

VariableDeclarationList :
  VariableDeclaration
  VariableDeclarationList , VariableDeclaration

VariableDeclaration :
  Identifier Initializeropt

Initializer :
  = AssignmentExpression

Description
If the variable statement occurs inside a FunctionDeclaration, the variables are defined with function-local scope in that function. Otherwise, they are defined with global scope, that is, they are created as members of the global object as described in section Error! Reference source not found. Variables are created when the execution scope is entered. A Block does not define a new execution scope. Only Program and FunctionDeclaration produce a new scope. Eval code and anonymous code also define a new execution scope, but these are not an explicit part of the grammar of ECMAScript. Variables are initialized to the undefined value when created. A variable with an Initializer is assigned the value of its AssignmentExpression when the VariableStatement is executed.

Semantics
The production VariableStatement : var VariableDeclarationList ; is evaluated as follows:
1. Evaluate VariableDeclarationList.
2. Return.

The production VariableDeclarationList : VariableDeclarationList , VariableDeclaration is evaluated as follows:
1. Evaluate VariableDeclarationList.
2. Evaluate VariableDeclaration.
3. Return.

The production VariableDeclaration : Identifier = AssignmentExpression is evaluated as follows:
1. Evaluate Identifier.
2. Evaluate AssignmentExpression.
3. Call GetValue(Result(2)).
4. Call PutValue(Result(1), Result(3)).
5. Return.

8.2 Empty Statement

Syntax

EmptyStatement :

; 

Semantics
The production EmptyStatement : ; is evaluated by taking no action.

8.3 Expression Statement

Syntax

ExpressionStatement :

Expression ; 

Semantics
The production ExpressionStatement : Expression ; is evaluated as follows:
1. Evaluate Expression.
2. Call GetValue(Result(1)).

8.4 The if Statement

Syntax

IfStatement :

if ( Expression ) Statement else Statement

if ( Expression ) Statement
Semantics
The production IfStatement : if ( Expression ) Statement, else Statement, is evaluated as follows:
1. Evaluate Expression.
2. Call GetValue(Result(1)).
3. Call ToBoolean(Result(2)).
4. If Result(3) is false, go to step 7.
5. Evaluate Statement1.
6. Return.
8. Return.

The production IfStatement : if ( Expression ) Statement is evaluated as follows:
1. Evaluate Expression.
2. Call GetValue(Result(1)).
3. Call ToBoolean(Result(2)).
4. If Result(3) is false, return.
5. Evaluate Statement.
6. Return.

8.5 ITERATION STATEMENTS

Syntax

```
IterationStatement :
    while ( Expression ) Statement
    for ( Expression_opt ; Expression_opt ; Expression_opt ) Statement
    for ( var VariableDeclarationList ; Expression_opt ; Expression_opt ) Statement
    for ( Expression in Expression ) Statement
    for ( var_opt Identifier Initializer_opt in Expression ) Statement
```

Description
These statements all define a “continue label” and a “break label” for use by an enclosed continue or break statement. For the purposes of this specification, a label is a step number in an algorithm. Continue labels are held in a continue label stack and break labels are held in a break label stack. These stacks are local to the current execution scope. To execute a continue or break statement, execution control is transferred to the label specified by the top value of the corresponding label stack. If an implementation of ECMAScript has distinct compile and execute phases, the label stacks need only be maintained during compilation as the label that a continue or break statement jumps to is not dependent on any runtime state.

The WithStatement affects both stacks for the purposes of clean up: to remove its object from the scope chain.

In algorithms, we use “PushBreak(n)” as short hand for “Push Step(n) on the break label stack”. Similarly we use “PushContinue(n)”, “PopBreak(n)” and “PopContinue(n)” as short hand for the obvious phrases. We use “JumpBreak” as short hand for “Transfer execution control to the position indicated by the top label of the break label stack” and similarly for “JumpContinue”.

8.5.1 The while Statement

The production IterationStatement : while ( Expression ) Statement is evaluated as follows:
1. PushContinue(3).
2. PushBreak(9).
3. Evaluate Expression.
4. Call GetValue(Result(3)).
5. Call ToBoolean(Result(4)).
6. If Result(5) is false, go to 9.
7. Evaluate Statement.
8. Go to step 3.
9. PopBreak(9).
10. PopContinue(3).
11. Return.

8.5.2 The \texttt{for} Statement

The production IterationStatement : \texttt{for ( Expression\_1 ; Expression\_2 ; Expression\_3 ) Statement} is evaluated as follows:
1. PushContinue(10).
2. PushBreak(13).
3. Evaluate Expression1.
4. Call GetValue(Result(3)).
5. Evaluate Expression2.
6. Call GetValue(Result(5)).
7. Call ToBoolean(Result(6)).
8. If Result(7) is false, go to step 13.
10. Evaluate Expression3.
11. Call GetValue(Result(10)).
12. Go to step 5.
13. PopBreak(13).
14. PopContinue(10).
15. Return.

If \texttt{Expression\_1} is omitted from the source text, steps 3 and 4 are omitted from execution. If \texttt{Expression\_2} is omitted from the source text, step 5 is omitted from execution and the result of step 5 is \texttt{true}. If \texttt{Expression\_3} is omitted from the source text, steps 10 and 11 are omitted from execution.

\textbf{Issue:} define the var version.

8.5.3 The \texttt{for..in} Statement

The production IterationStatement : \texttt{for (Expression\_1 in Expression\_2 ) Statement} is evaluated as follows:
1. PushContinue(6).
2. PushBreak(11).
3. Evaluate Expression2.
4. CallGetValue(Result(3)).
5. Call ToObject(Result(4)).
6. Get the name of the next property of Result(5) which doesn’t have the DontEnum attribute. If there is no such property, go to step 11.
7. Evaluate Expression1.
8. Call PutValue(Result(7), Result(6)).
11. PopBreak(11).
12. PopContinue(6).
13. Return.
The mechanics of enumerating the properties (step 6) is implementation dependent. The order of enumeration is defined by the object. Properties of the object being enumerated may be deleted during enumeration. If a property that has not yet been visited during enumeration is deleted, then it will not be visited. If new properties are added to the object being enumerated during enumeration, the newly added properties are not guaranteed to be visited in the active enumeration.

**Issue:** define the var version.

**Issue:** Need to talk about enumerating properties of the prototype, and so on, recursively. Are shadowed properties of the prototype(s) enumerated? (I hope not!)

### 8.6 The `continue` Statement

**Syntax**

```
ContinueStatement :
  continue ;
```

An ECMAScript program is considered syntactically incorrect and may not be executed at all if it contains a `continue` statement that is not within at least one `while` or `for` statement. The `continue` statement can only be used when the continue label stack contains at least one label. This is only the case inside a `while`, `for`, or `for..in` loop. The `continue` statement is evaluated as:

1. JumpContinue.

See section **Iteration Statements** for a description of the continue label stack and the JumpContinue directive.

### 8.7 The `break` Statement

**Syntax**

```
BreakStatement :
  break ;
```

An ECMAScript program is considered syntactically incorrect and may not be executed at all if it contains a `break` statement that is not within at least one `while` or `for` statement. The `break` statement can only be used when the break label stack contains at least one label. This is only the case inside a `while`, `for`, or `for..in` loop. The `break` statement is evaluated as:

1. JumpBreak

See section **Iteration Statements** for a description of the break label stack and the JumpBreak directive.

### 8.8 The `return` Statement

**Syntax**

```
ReturnStatement :
  return [no LineTerminator here] Expression_opt ;
```

The `return` statement can only be used inside the `Block` of a `FunctionDeclaration`. It causes a function to cease execution and return a value to the caller. If `Expression` is omitted, the return value is the `undefined` value. Otherwise, the return value is the value of `Expression`.

### 8.9 The `with` Statement

**Syntax**

```
WithStatement :
  with ( Expression ) Statement
```
Description
The WithStatement affects the break label stack and continue label stack for clean up purposes only.

Semantics
The production WithStatement : with ( Expression ) Statement is evaluated as follows:
1. If the continue label stack is not empty, PushContinue(12).
2. If the break label stack is not empty, PushBreak(16).
3. Evaluate Expression.
4. Call GetValue(Result(3)).
5. Call ToObject(Result(4)).
6. Add Result(5) to the front of the scope chain.
7. Evaluate Statement.
8. Remove Result(5) from the front of the scope chain.
9. If the break label stack is not empty, PopBreak(16).
10. If the continue label stack is not empty, PopContinue(12).
11. Return.
12. Remove Result(5) from the front of the scope chain.
13. If the break label stack is not empty, PopBreak(16).
14. PopContinue(12).
15. JumpContinue.
16. Remove Result(5) from the front of the scope chain.
17. PopBreak(16).
18. If the continue label stack is not empty, PopContinue(12).

Discussion
Most of the complexity of this algorithm is to handle jumps out of the WithStatement. Any jumps out of the WithStatement must be trapped to remove the object from the scope chain.
9 FUNCTION DEFINITION

Syntax

\[ \text{FunctionDeclaration} : \]
\[ \text{function} \ \text{Identifier} \ (\text{FormalParameterList} \text{opt}) \ \text{Block} \]

\[ \text{FormalParameterList} : \]
\[ \text{Identifier} \]
\[ \text{FormalParameterList} \ , \ \text{Identifier} \]

Semantics

Defines a property of the global object whose name is the \text{Identifier} and whose value is a function object with the given parameter list and statements. If the function definition is supplied text to the \texttt{eval} function and the calling context has an activation object then the declared function is added to the activation object.
10 Program

Syntax

Program :
    SourceElements EndOfSource

SourceElements :
    SourceElement
    SourceElements SourceElement

SourceElement :
    Statement
    FunctionDefinition
11 NATIVE ECMASCRIP T OBJECTS

There are certain built-in objects available whenever an ECMAScript program begin execution. One, the
global object, is in the scope chain of the executing program. Others are accessible as permanent properties
of the global object.
Some objects are constructors: they are functions intended for use with the \texttt{new} operator. For each built-in
constructor, this specification describes the arguments required by that constructor function, properties of
the constructor object, properties of the prototype object of that constructor, and properties of specific
object instances returned by a \texttt{new} expression that invokes that constructor.

11.1 THE GLOBAL OBJECT
The global object does not have a [[Construct]] property; it is not possible to use the global object as a
constructor with the \texttt{new} operator.

11.1.1 Value Properties of the Global Object

11.1.2 Function Properties of the Global Object

11.1.2.1 \texttt{eval(x)}

11.1.2.2 \texttt{parseInt(string, radix)}

11.1.2.3 \texttt{parseFloat(string)}

11.1.2.4 \texttt{escape(string)}

11.1.2.5 \texttt{unescape(string)}

11.2 OBJECT OBJECTS

11.2.1 The Object Constructor

11.2.1.1 \texttt{new Object(value)}

11.2.1.2 \texttt{new Object()}

11.2.2 Properties of the Object Constructor
The value of the internal [[Prototype]] property of the Object constructor is the Function prototype object.
Besides the internal [[Call]] and [[Constructor]] properties, the Object constructor has the following
property:
11.2.2.1 Object.prototype

The value of `Object.prototype` is the built-in Object prototype object.

11.2.3 Properties of the Object Prototype Object

11.2.4 Properties of Object Instances

  Constructor
  [[Get]]
  [[Put]]
  [[CanPut]]
  [[Prototype]]
  [[HasProperty]]
  [[Construct]]

11.3 FUNCTION OBJECTS

11.3.1 The Function Constructor

11.3.2 Properties of the Function Constructor

11.3.3 Properties of the Function Prototype Object

11.3.4 Properties of Function Instances

11.4 ARRAY OBJECTS

11.4.1 The Array Constructor

11.4.1.1 `new Array(item0, item1, item2, . . .)`

11.4.1.2 `new Array(len)`

11.4.1.3 `new Array()`

11.4.2 Properties of the Array Constructor

  The value of the internal `[[Prototype]]` property of the Array constructor is the Function prototype object. Besides the internal `[[Call]]` and `[[Constructor]]` properties, the Array constructor has the following property:

11.4.2.1 Array.prototype

  The value of `Array.prototype` is the built-in Array prototype object.

11.4.3 Properties of the Array Prototype Object

  The value of `Array.prototype` is the built-in Array prototype object. As a result, the Array prototype object inherits the internal `[[Get]]`, `[[CanPut]]`, and `[[HasProperty]]` methods from the Object prototype object.

  The Array prototype object has its own internal `[[Put]]` method that keeps the `length` property of an array instance up to date.
In following descriptions of functions that are properties of the Array prototype object, the phrase “this Array object” refers to the object that is the `this` value for the invocation of the function; it is an error if this does not refer to an object for which the Array prototype object is not either directly or indirectly a prototype.

11.4.3.1 join

11.4.3.2 reverse

11.4.3.3 sort

11.4.4 Properties of Array Instances

String instances inherit properties from the String prototype object and also have the following property.

11.4.4.1 length

11.5 STRING OBJECTS

11.5.1 The String Constructor

11.5.2 Properties of the String Constructor

The value of the internal `[[Prototype]]` property of the Object constructor is the Function prototype object. Besides the internal `[[Call]]` and `[[Constructor]]` properties, the String constructor has the following property:

11.5.2.1 String.prototype

The value of `String.prototype` is the built-in String prototype object.

11.5.3 Properties of the String Prototype Object

In following descriptions of functions that are properties of the String prototype object, the phrase “this String object” refers to the object that is the `this` value for the invocation of the function; it is an error if this does not refer to an object for which the String prototype object is not either directly or indirectly a prototype.

11.5.3.1 toString()

The String value represented by this String object is returned.
11.5.3.2 valueOf()
11.5.3.3 charAt
11.5.3.4 indexOf
11.5.3.5 lastIndexOf
11.5.3.6 split
11.5.3.7 substring
11.5.3.8 toLowerCase
11.5.3.9 toUpperCase

11.5.4 Properties of String Instances
String instances inherit properties from the String prototype object and also have the following property.
11.5.4.1 length
The number of characters in the String value represented by this String object.
Once a String object is created, this property is unchanging.

11.6 BOOLEAN OBJECTS

11.6.1 The Boolean Constructor
11.6.1.1 new Boolean(value)
11.6.1.2 new Boolean()

11.6.2 Properties of the Boolean Constructor
The value of the internal [[Prototype]] property of the Boolean constructor is the Function prototype object.
Besides the internal [[Call]] and [[Constructor]] properties, the Number constructor has the following property:

11.6.2.1 Boolean.prototype
The value of Boolean.prototype is the built-in Boolean prototype object.

11.6.3 Properties of the Boolean Prototype Object
In following descriptions of functions that are properties of the Boolean prototype object, the phrase “this Boolean object” refers to the object that is the this value for the invocation of the function; it is an error if this does not refer to an object for which the Boolean prototype object is not either directly or indirectly a prototype.

11.6.3.1 toString()
If this Boolean object represents true, then the string “true” is returned. Otherwise, this Boolean object must represent false, and the string “false” is returned.
11.6.3.2 `valueOf()`

11.6.4 Properties of Boolean Instances
Boolean instances have no special properties beyond those inherited from the Boolean prototype object.

11.7 **NUMBER OBJECTS**

11.7.1 The Number Constructor

11.7.1.1 `new Number(value)`

11.7.1.2 `new Number()`

11.7.2 Properties of the Number Constructor
The value of the internal `[[Prototype]]` property of the Number constructor is the Function prototype object. Besides the internal `[[Call]]` and `[[Constructor]]` properties, the Number constructor has the following property:

11.7.2.1 `Number.prototype`
The value of `Number.prototype` is the built-in Number prototype object.

11.7.2.2 `Number.NaN`
The value of `Number.NaN` is NaN.

11.7.3 Properties of the Number Prototype Object
In following descriptions of functions that are properties of the Number prototype object, the phrase “this Number object” refers to the object that is the `this` value for the invocation of the function; it is an error if this does not refer to an object for which the Number prototype object is not either directly or indirectly a prototype.

11.7.3.1 `toString()`

11.7.3.2 `valueOf()`

11.7.4 Properties of Number Instances
Number instances have no special properties beyond those inherited from the Number prototype object.

11.8 **THE MATH OBJECT**
The Math object is merely a single object that has some named properties, some of which are functions. The Math object does not have a `[[Construct]]` property; it is not possible to use the Math object as a constructor with the `new` operator.

Recall that, in this specification, the phrase “the number value for x” means “the value of number type, not NaN but possibly infinite, that is closer than any other value of number type to the mathematical value x, but if x lies exactly halfway between two such values then the number value whose least significant bit is 0 is chosen”.

5787
11.8.1 Value Properties of the Math Object

11.8.1.1 E
The number value for $e$, the base of the natural logarithms, which is approximately $2.7182818284590452354$.

11.8.1.2 LN10
The number value for the natural logarithm of 10, which is approximately $2.302585092994046$.

11.8.1.3 LN2
The number value for the natural logarithm of 2, which is approximately $0.6931471805599453$.

11.8.1.4 LOG2E
The number value for the base-2 logarithm of $e$, the base of the natural logarithms; this value is approximately $1.4426950408889634$. (Note that the value of $\text{Math.LOG2E}$ is approximately the reciprocal of the value of $\text{Math.LN2}$.)

11.8.1.5 LOG10E
The number value for the base-2 logarithm of $e$, the base of the natural logarithms; this value is approximately $0.4342944819032518$. (Note that the value of $\text{Math.LOG2E}$ is approximately the reciprocal of the value of $\text{Math.LN2}$.)

11.8.1.6 PI
The number value for $\pi$, the ratio of the circumference of a circle to its diameter, which is approximately $3.14159265358979323846$.

11.8.1.7 SQRT1_2
The number value for the square root of 1/2, which is approximately $0.7071067811865476$. (Note that the value of $\text{Math.SQRT1_2}$ is approximately the reciprocal of the value of $\text{Math.SQRT2}$.)

11.8.1.8 SQRT2
The number value for the square root of 2, which is approximately $1.4142135623730951$.

11.8.2 Function Properties of the Math Object
Every function listed in this section applies the ToNumber operator to each of its arguments (in left-to-right order if there is more than one) and then performs a computation on the resulting number value(s).

The behavior of the functions acos, asin, atan, atan2, cos, exp, log, pow, sin, and sqrt is not precisely specified here. They are intended to compute approximations to the results of familiar mathematical functions, but some latitude is allowed in the choice of approximation algorithms. The general intent is that an implementor should be able to use the same mathematical library for ECMAScript on a given hardware platform that is available to C programmers on that platform. Nevertheless, this specification recommends (though it does not require) the approximation algorithms for IEEE 754 arithmetic contained in $\text{fdlibm}$, the freely distributable mathematical library [XXXREF]. This specification also requires specific results for certain argument values that represent boundary cases of interest.

11.8.2.1 abs(x)
Returns the absolute value of its argument; in general, the result has the same magnitude as the argument but has positive sign.

- If the argument is $\text{NaN}$, the result is $\text{NaN}$.
- If the argument is \(-0\), the result is \(+0\).
- If the argument is \(-\text{Infinity}\), the result is \(+\text{Infinity}\).

11.8.2.2 acos(x)

Returns an implementation-dependent approximation to the arc cosine of the argument. The result is expressed in radians and ranges from \(+0\) to \(+\pi\).
- If the argument is \text{NaN}, the result is \text{NaN}.
- If the argument is greater than \(1\), the result is \text{NaN}.
- If the argument is less than \(-1\), the result is \text{NaN}.
- If the argument is exactly \(1\), the result is \(+0\).

11.8.2.3 asin(x)

Returns an implementation-dependent approximation to the arc sine of the argument. The result is expressed in radians and ranges from \(-\pi/2\) to \(+\pi/2\).
- If the argument is \text{NaN}, the result is \text{NaN}.
- If the argument is greater than \(1\), the result is \text{NaN}.
- If the argument is less than \(-1\), the result is \text{NaN}.
- If the argument is \(+0\), the result is \(+0\).
- If the argument is \(-0\), the result is \(-0\).

11.8.2.4 atan(x)

Returns an implementation-dependent approximation to the arc tangent of the argument. The result is expressed in radians and ranges from \(-\pi/2\) to \(+\pi/2\).
- If the argument is \text{NaN}, the result is \text{NaN}.
- If the argument is \(+0\), the result is \(+0\).
- If the argument is \(-0\), the result is \(-0\).
- If the argument is \(+\text{Infinity}\), the result is an implementation-dependent approximation to the number value for \(+\pi/2\).
- If the argument is \(-\text{Infinity}\), the result is an implementation-dependent approximation to the number value for \(-\pi/2\).

11.8.2.5 atan2(y, x)

Returns an implementation-dependent approximation to the arc tangent of the quotient \(y/x\) of the arguments \(y\) and \(x\), where the signs of the arguments are used to determine the quadrant of the result. Note that it is intentional and traditional for the two-argument arc tangent function that the argument named \(y\) be first and the argument named \(x\) be second. The result is expressed in radians and ranges from \(-\pi\) to \(+\pi\).
- If either argument is \text{NaN}, the result is \text{NaN}.
- If \(y>0\) and \(x\) is \(+0\), the result is an implementation-dependent approximation to the number value for \(+\pi/2\).
- If \(y>0\) and \(x\) is \(-0\), the result is an implementation-dependent approximation to the number value for \(+\pi/2\).
- If \(y\) is \(+0\) and \(x>0\), the result is \(+0\).
- If \(y\) is \(+0\) and \(x\) is \(+0\), the result is \(+0\).
- If \(y\) is \(+0\) and \(x\) is \(-0\), the result is an implementation-dependent approximation to the number value for \(\pi\).
- If \(y\) is \(+0\) and \(x<0\), the result is an implementation-dependent approximation to the number value for \(\pi\).
- If \(y\) is \(-0\) and \(x>0\), the result is \(-0\).
- If \(y\) is \(-0\) and \(x\) is \(+0\), the result is \(-0\).

5987
• If \( y = -0 \) and \( x = -0 \), the result is an implementation-dependent approximation to the number value for \(-\pi\).
• If \( y = -0 \) and \( x < 0 \), the result is an implementation-dependent approximation to the number value for \(-\pi/2\).
• If \( y < 0 \) and \( x = +0 \), the result is an implementation-dependent approximation to the number value for \(-\pi/2\).
• If \( y < 0 \) and \( x = -0 \), the result is an implementation-dependent approximation to the number value for \(-\pi/2\).
• If \( y > 0 \) and \( x \) is \(+\infty\), the result is \(+0\).
• If \( y > 0 \) and \( x \) is \(-\infty\), the result is \(-\infty\).
• If \( y > 0 \) and \( y \) is finite and \( x \) is \(+\infty\), the result is \(+0\).
• If \( y > 0 \) and \( y \) is finite and \( x \) is \(-\infty\), the result is \(-\infty\).

11.8.2.6 ceil(x)

Returns the smallest (closest to negative infinity) number value that is not less than the argument and is equal to a mathematical integer. If the argument is already an integer, the result is the argument itself.
• If the argument is \( NaN \), the result is \( NaN \).
• If the argument is \(+0\), the result is \(+0\).
• If the argument is \(-0\), the result is \(-0\).
• If the argument is \(+\infty\), the result is \(+\infty\).
• If the argument is \(-\infty\), the result is \(-\infty\).
• If the argument is less than \( 0 \) but greater than \(-1 \), the result is \(-0\).

The value of \( Math.ceil(x) \) is the same as the value of \(-Math.floor(-x)\).

11.8.2.7 cos(x)

Returns an implementation-dependent approximation to the cosine of the argument. The argument is expressed in radians.
• If the argument is \( NaN \), the result is \( NaN \).
• If the argument is \(+0\), the result is \( 1 \).
• If the argument is \(-0\), the result is \( -1 \).
• If the argument is \(+\infty\), the result is \( NaN \).
• If the argument is \(-\infty\), the result is \( NaN \).
11.8.2.8 exp(x)

Returns an implementation-dependent approximation to the exponential function of the argument (\(e\) raised to the power of the argument, where \(e\) is the base of the natural logarithms).

- If the argument is \(\text{NaN}\), the result is \(\text{NaN}\).
- If the argument is +0, the result is 1.
- If the argument is -0, the result is 1.
- If the argument is +\(\text{Infinity}\), the result is +\(\text{Infinity}\).
- If the argument is -\(\text{Infinity}\), the result is +0.

11.8.2.9 floor(x)

Returns the smallest (closest to negative infinity) number value that is not less than the argument and is equal to a mathematical integer. If the argument is already an integer, the result is the argument itself.

- If the argument is \(\text{NaN}\), the result is \(\text{NaN}\).
- If the argument is +0, the result is +0.
- If the argument is -0, the result is -0.
- If the argument is +\(\text{Infinity}\), the result is +\(\text{Infinity}\).
- If the argument is -\(\text{Infinity}\), the result is -\(\text{Infinity}\).
- If the argument is greater than 0 but less than 1, the result is +0.

11.8.2.10 log(x)

Returns an implementation-dependent approximation to natural logarithm of the argument.

- If the argument is \(\text{NaN}\), the result is \(\text{NaN}\).
- If the argument is less than 0, the result is \(\text{NaN}\).
- If the argument is +0 or -0, the result is -\(\text{Infinity}\).
- If the argument is 1, the result is +0.
- If the argument is +\(\text{Infinity}\), the result is +\(\text{Infinity}\).

11.8.2.11 max(x, y)

Returns the larger of the two arguments.

- If either argument is \(\text{NaN}\), the result is \(\text{NaN}\).
- If \(x > y\), the result is \(x\).
- If \(y > x\), the result is \(y\).
- If \(x\) is +0 and \(y\) is +0, the result is +0.
- If \(x\) is +0 and \(y\) is -0, the result is +0.
- If \(x\) is -0 and \(y\) is +0, the result is +0.
- If \(x\) is -0 and \(y\) is -0, the result is -0.

11.8.2.12 min(x, y)

Returns the smaller of the two arguments.

- If either argument is \(\text{NaN}\), the result is \(\text{NaN}\).
- If \(x < y\), the result is \(x\).
- If \(y < x\), the result is \(y\).
- If \(x\) is +0 and \(y\) is +0, the result is +0.
- If \(x\) is +0 and \(y\) is -0, the result is +0.
- If \(x\) is -0 and \(y\) is +0, the result is -0.
- If \(x\) is -0 and \(y\) is -0, the result is -0.

11.8.2.13 pow(x, y)

Returns an implementation-dependent approximation to the result of raising \(x\) to the power \(y\).
• If \(y\) is \(\text{NaN}\), the result is \(\text{NaN}\).
• If \(y\) is +0, the result is 1, even if \(x\) is \(\text{NaN}\).
• If \(y\) is −0, the result is 1, even if \(x\) is \(\text{NaN}\).
• If \(x\) is \(\text{NaN}\) and \(y\) is nonzero, the result is \(\text{NaN}\).
• If \(\text{abs}(x)>1\) and \(y\) is \(+\text{Infinity}\), the result is \(+\text{Infinity}\).
• If \(\text{abs}(x)>1\) and \(y\) is \(-\text{Infinity}\), the result is +0.
• If \(\text{abs}(x)==1\) and \(y\) is \(+\text{Infinity}\), the result is \(\text{NaN}\).
• If \(\text{abs}(x)==1\) and \(y\) is \(-\text{Infinity}\), the result is \(\text{NaN}\).
• If \(x\) is \(-\text{Infinity}\) and \(y>0\) and \(y\) is an odd integer, the result is \(-\text{Infinity}\).
• If \(x\) is \(-\text{Infinity}\) and \(y>0\) and \(y\) is not an odd integer, the result is +\(\text{Infinity}\).
• If \(x\) is \(-\text{Infinity}\) and \(y<0\) and \(y\) is an odd integer, the result is \(-0\).
• If \(x\) is \(-\text{Infinity}\) and \(y<0\) and \(y\) is not an odd integer, the result is +\(0\).
• If \(x\) is +0 and \(y<0\), the result is +\(\text{Infinity}\).
• If \(x\) is −0 and \(y>0\) and \(y\) is an odd integer, the result is −0.
• If \(x\) is −0 and \(y>0\) and \(y\) is not an odd integer, the result is +0.
• If \(x\) is −0 and \(y<0\) and \(y\) is an odd integer, the result is −\(\text{Infinity}\).
• If \(x\) is −0 and \(y<0\) and \(y\) is not an odd integer, the result is +\(\text{Infinity}\).

11.8.2.14 random()

Returns a number value with positive sign, greater than or equal to 0 but less than 1, chosen randomly or pseudorandomly with approximately uniform distribution over that range, using an implementation-dependent algorithm or strategy. This function takes no arguments.

11.8.2.15 round(x)

Returns the number value that is closest to the argument and is equal to a mathematical integer. If two integer number values are equally close to the argument, then the result is the number value that is closer to positive infinity. If the argument is already an integer, the result is the argument itself.
• If the argument is \(\text{NaN}\), the result is \(\text{NaN}\).
• If the argument is +0, the result is +0.
• If the argument is −0, the result is −0.
• If the argument is +\(\text{Infinity}\), the result is +\(\text{Infinity}\).
• If the argument is −\(\text{Infinity}\), the result is −\(\text{Infinity}\).
• If the argument is greater than 0 but less than 0.5, the result is +0.
• If the argument is less than 0 but greater than or equal to −0.5, the result is −0.

The value of \(\text{Math.round}(x)\) is the same as the value of \(\text{Math.floor}(x+0.5)\). Note that \(\text{Math.round}(3.5)\) returns 4, but \(\text{Math.round}(-3.5)\) returns −3.

11.8.2.16 sin(x)

Returns an implementation-dependent approximation to the sine of the argument. The argument is expressed in radians.
• If the argument is \(\text{NaN}\), the result is \(\text{NaN}\).
• If the argument is +0, the result is +0.
• If the argument is −0, the result is −0.
• If the argument is \( +\text{Infinity} \) or \( -\text{Infinity} \), the result is \( \text{NaN} \).

**11.8.2.17 sqrt(x)**

Returns an implementation-dependent approximation to the square root of the argument.

- If the argument is \( \text{NaN} \), the result is \( \text{NaN} \).
- If the argument less than \( 0 \), the result is \( \text{NaN} \).
- If the argument is \( +0 \), the result is \( +0 \).
- If the argument is \( -0 \), the result is \( -0 \).
- If the argument is \( +\text{Infinity} \), the result is \( +\text{Infinity} \).

**11.8.2.18 tan(x)**

Returns an implementation-dependent approximation to the tangent of the argument. The argument is expressed in radians.

- If the argument is \( \text{NaN} \), the result is \( \text{NaN} \).
- If the argument is \( +0 \), the result is \( +0 \).
- If the argument is \( -0 \), the result is \( -0 \).
- If the argument is \( +\text{Infinity} \) or \( -\text{Infinity} \), the result is \( \text{NaN} \).
12 Errors

This specification specifies the last possible moment an error occurs. A given implementation may generate errors sooner (e.g. at compile-time). Doing so may cause differences in behavior among implementations. Notably, if runtime errors become catchable in future versions, a given error would not be catchable if an implementation generates the error at compile-time rather than runtime.

An ECMAScript compiler should detect errors at compile time in all code presented to it, even code that detailed analysis might prove to be “dead” (never executed). A programmer should not rely on the trick of placing code within an `if (false)` statement, for example, to try to suppress compile-time error detection.

Issue: If a compiler can prove that a construct cannot execute without error under any circumstances, then it may issue a compile-time error even though the construct might not be executed at all?
13 REFERENCES

APPENDIX A: OPEN ISSUES

A.1 Break and continue label stacks

The break and continue label stacks and their associated machinery complicate the description of control flow in ECMAScript. Moreover, the current description does not give a clear account of how JumpContinue discards the implicit control stacks that support the execution of the pseudocode procedures in this document.

I would like to propose the rewriting of the behavior of statements into the style used in the Java Language Specification, wherein one speaks of a statement as completing “normally” or “abruptly (for a reason)”. The advantage of this descriptive strategy is that then there are no nonlocal transfers within the pseudocode and all descriptions of control flow behavior are local.

As examples, here are accounts of the break, continue, if, and while statements in this style, which should illustrate all the relevant concepts:

The production BreakStatement: break ; is evaluated as follows:
1. Return “abrupt completion because of break”.

The production ContinueStatement: continue ; is evaluated as follows:
1. Return “abrupt completion because of continue”.

The production IfStatement: if ( Expression ) Statement, else Statement, is evaluated as follows:
1. Evaluate Expression.
2. Call GetValue(Result(1)).
3. Call ToBoolean(Result(2)).
4. If Result(3) is false, go to step 7.
5. Evaluate Statement1.
6. Return Result(5).
8. Return Result(7).

The production IterationStatement: while ( Expression ) Statement is evaluated as follows:
1. Evaluate Expression.
2. Call GetValue(Result(1)).
3. Call ToBoolean(Result(2)).
4. If Result(3) is false, go to step 10.
5. Evaluate Statement.
6. If Result(5) is “abrupt completion because of break”, go to step 10.
7. If Result(5) is “abrupt completion because of continue”, go to step 1.
8. If Result(5) is “abrupt completion because of return of value V”, return Result(5).
9. Go to step 3.
10. Return “normal completion”.

Note that the only change to the description of if is to return the results of substatement evaluation. On the other hand, the description of while has to take the various kinds of abrupt completion into account. A break causes the while statement to complete normally; a continue is treated as if the substatement
had completed normally; and a return causes the **while** statement to terminate immediately and to propagate the return action.

**THIS WAS AGREED TO ON FEBRUARY 28 BUT STILL NEEDS TO BE DONE.**

### A.2 Eval Function

Define object scoping within Eval block.

### A.3 Host-Supplied Members of Scope Chains vs. Implicit This

### A.4 Escape Sequences in String Literals

It was agreed at a previous meeting that any character could be preceded by a backslash in a string literal. Question: was it intended to allow `<CR>` or `<LF>` in a string literal if preceded by a backslash? I assumed not and wrote the grammar accordingly, but would like to have this point discussed.

### A.5 Break, Continue, Return in Wrong Place

What is the behavior of an ECMAScript program if it executes a break or continue not textually contained within a loop, or a return not textually within a function body? Are such errors guaranteed to be caught at compile time, or may they be detected at run time? (JavaScript document says it must be a compile-time error, Jscript document is less clear.)

### A.6 Math Functions

Are the math functions intended to be completely, guaranteed portable, or are they intended to be "whatever the host machine C library provides"? Should the boundary cases (infinities, zero, NaNs) be tied down in the manner now customary for IEEE arithmetic (I believe Java and C9X agree on these boundary cases)?

### A.2 ToString Applied to a Number Type

Should the following additional constraint be added to ToString applied to a number type?

The decimal string produced must be as close in its mathematical value to the mathematical value of the original number as any other decimal string with the same number of digits; and if two decimal strings of the same minimal length would be equally close in value to the original number, then the decimal string whose last digit is even should be chosen.

### A.3 ++ and -- Operators

The increment operators need to be described more carefully in terms of IEEE 754 addition and subtraction operations.

### A.4 Infinity and NaN Literals

I (Guy Steele) recommend that literals `NaN` and `Infinity` be added to the language, and that `Infinity` be recognized when ToNumber is applied to a string (right now it produces NaN!). For backward compatibility, the construction `Number.NaN` would have to continue to work.
APPENDIX B: PROPOSED EXTENSIONS

B.1 The Class Statement¹

Syntax

\[
\text{ClassDeclaration :} \\
\text{class Identifier FormalParameters opt ExtendsClause opt \{ ClassBody \}}
\]

\[
\text{FormalParameters :} \\
( \text{FormalParameterList opt})
\]

\[
\text{FormalParameterList :} \\
\text{Identifier} \\
\text{FormalParameterList , Identifier}
\]

\[
\text{ExtendsClause :} \\
\text{extends Identifier ActualArguments opt}
\]

\[
\text{ActualArguments :} \\
( \text{ExpressionList opt})
\]

\[
\text{ClassBody :} \\
\text{Constructor opt Methods opt}
\]

\[
\text{Constructor :} \\
\text{StatementList}
\]

\[
\text{Methods :} \\
\text{FunctionDefinition} \\
\text{Methods FunctionDefinition}
\]

Semantics

Similar to a function except:

- The class name space is global but distinct from the global function name space.
- The functions (methods) defined within a class definition are in a name space private to the class.
- The inclusion of methods automatically creates one property in the constructed object for each method defined.
- Classes may not be called directly but rather can only be used via the **new** operator.
B.2 The Try and Throw Statements

B.2.1 The try Statement

A try statement executes a block. If a value is thrown and the try statement has one or more catch clauses that can catch it, then control will be transferred to the first such catch clause. If the try statement has a finally clause, then the finally block of code is executed no matter whether the try block completes normally or abruptly and regardless of whether a catch clause is first given control.

\[
\text{TryStatement :}
\]
\[
\begin{align*}
\text{try & Block Catches} \\
\text{try & Block Catchesopt FinallyClause}
\end{align*}
\]

Catches:

CatchClause

CatchClause

Catches CatchClause

CatchClause:

\[
\text{catch ( FormalParameter ) Block}
\]

FinallyClause:

\[
\text{finally Block}
\]

B.2.2 The Throw Statment

A throw statement causes an exception to be thrown. The result is an immediate transfer of control that may exit multiple statements and method invocations until a try statement is found that catches the thrown value. If no such try statement is found, then a runtime error is generated.

\[
\text{ThrowStatement :}
\]
\[
\text{throw Expression}
\]

B.3 The Date Type

The Date Type is used to represent date and time. It is a Julian value on which certain operations such as date arithmetic are defined. Arithmetic operators, relational operators and equality operators apply to this type.

Note 1: Of the three current ECMAScript implementations, only the Borland implementation currently supports date operators. This feature is really just a convenience that can be implemented with Date Object methods. However, the same argument can be made for the String type.

Note 2: Of the three current ECMAScript implementations, only the Borland implementation currently implements dates as Julian dates and thus dates before (January 1970). Without this representation, dates are very limited in their usage (i.e. you cannot otherwise represent arbitrary dates, for example from existing databases)

B.3.1 ToDate

The operator ToDate attempts to convert its argument to a value of subtype Date Object according to the following table:

<table>
<thead>
<tr>
<th>Input Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>Blank date value.</td>
</tr>
<tr>
<td>Null</td>
<td>Blank date value.</td>
</tr>
<tr>
<td>-------</td>
<td>-------------------</td>
</tr>
<tr>
<td>Boolean</td>
<td>Blank date value.</td>
</tr>
<tr>
<td>Number</td>
<td>Blank date value.</td>
</tr>
<tr>
<td>String</td>
<td>See discussion below.</td>
</tr>
<tr>
<td>Date</td>
<td>Return the input argument (no conversion)</td>
</tr>
<tr>
<td>Object</td>
<td>Apply the following steps:</td>
</tr>
<tr>
<td></td>
<td>1. Call ToPrimitive(input argument, hint Date).</td>
</tr>
<tr>
<td></td>
<td>2. Call ToDate(Result(1)).</td>
</tr>
<tr>
<td></td>
<td>Return Result(2).</td>
</tr>
</tbody>
</table>

### B.3.2 ToDate Applied to the String Type

**Issue:** define this.

### B.4 Implicit This

In function code where the function definition specifies the `implicit` keyword, the `this` object is placed in the scope chain immediately before the global object.

### B.5 The switch Statement

**Syntax**

```
SwitchStatement :  
  switch ( Expression ) CaseBlock

CaseBlock :  
  { CaseClauses_opt }
  { CaseClauses_opt DefaultClause CaseClauses_opt }

CaseClauses :  
  CaseClause
  CaseClauses CaseClause

CaseClause :  
  case Expression : StatementList_opt

DefaultClause :  
  default : StatementList_opt
```

**Semantics**

The `SwitchStatement` adds a label to the break label stack, which is described in section Iteration Statements. It also adds a label to the continue label stack for clean up purposes only.

The production `SwitchStatement : switch ( Expression ) CaseBlock` is evaluated as follows:

1. If the continue label stack is not empty, PushContinue(9).
2. PushBreak(6).
3. Evaluate Expression.
4. Call GetValue(Result(3)).
5. Evaluate CaseBlock, passing it Result(4) as a parameter.
6. PopBreak(6).
7. If the continue label stack is not empty, PopContinue(9).
8. Return.
10. PopContinue(9).
11. JumpContinue.

The production \textit{CaseBlock} : \{ \textit{CaseClauses}, \textit{DefaultClause} \textit{CaseClauses}_2 \} is given an input parameter, \textit{input}, and is evaluated as follows:

1. For the next CaseClause in \textit{CaseClauses}_1, in source text order, evaluate CaseClause. If there is no such CaseClause, go to step 6.
2. If input is not equal to Result(1) (as defined by the != operator), go to step 1.
3. Execute the StatementList of this CaseClause.
4. Execute the StatementList of each subsequent CaseClause in \textit{CaseClauses}_1.
5. Go to step 11.
6. For the next CaseClause in \textit{CaseClauses}_2, in source text order, evaluate CaseClause. If there is no such CaseClause, go to step 11.
7. If input is not equal to Result(6) (as defined by the != operator), go to step 6.
8. Execute the StatementList of this CaseClause.
9. Execute the StatementList of each subsequent CaseClause in \textit{CaseClauses}_2.
10. Return.
11. Execute the StatementList of DefaultClause.
12. Execute the StatementList of each CaseClause in \textit{CaseClauses}_2.
13. Return.

If \textit{CaseClauses}_1 is omitted, steps 1 through 5 are omitted from execution. If \textit{DefaultClause} is omitted (in which case \textit{CaseClauses}_2 is also omitted), steps 11 and 12 are omitted from execution. If \textit{CaseClauses}_2 is omitted, steps 6 through 10 and 12 are omitted from execution.

Typically there will be a \texttt{break} statement in one or more \textit{StatementList}, which will transfer execution back to the break label for the \textit{SwitchStatement}.

The production \textit{CaseClause} : \textit{case} \textit{Expression} : \textit{StatementList\_opt} is evaluated as follows:

1. Evaluate \textit{Expression}.
2. Call GetValue(Result(1)).
3. Return Result(2).

Note that evaluating \textit{CaseClause} does not execute the associated \textit{StatementList}. It simply evaluates the \textit{Expression} and returns the value, which the \textit{CaseBlock} algorithm uses to determine which \textit{StatementList} to start executing.

\section*{B.6 Conversion Functions}

The conversion functions, \texttt{ToBoolean}, \texttt{ToNumber}, \texttt{ToInteger}, \texttt{ToInt32}, \texttt{ToUint32}, \texttt{ToString} and \texttt{ToObject} are global functions that operate as described in this document.

\section*{B.7 Assignment-Only Operator ( \(\ := \) )}

The assignment-only operator operates identically to the assignment operator \(( = )\) except that if the given lvalue doesn’t already exist, prior to the statements execution, a runtime error is generated.

\section*{B.8 Sealing of an Object}

A facility to prevent an object from being further expanded may be invoked at any time after an object has been constructed. This is semantically the dynamic equivalent to the static Java final class modifier. This facility may be implemented as a method of the object, a global function, or, if the \texttt{class} statement is adopted, as a class modifier to \texttt{class}. Once an object has been sealed or finalized, any attempt to add a new property to the object results in a runtime error.
B.9 THE ARGUMENTS KEYWORD

The `arguments` keyword refers to the arguments object. Within global code, `arguments` returns `null`. Within eval code, `arguments` returns the same value as in the calling context.

**Discussion:**
This interpretation of the "arguments" within a function body differs from existing practice but has two important advantages over the current mechanism:

1. It can be much more efficiently implemented, especially in the case of recursive functions.
2. It eliminates some complex and confusing semantic issues that arise as a result of the arguments to an activation frame being accessible from a function object.

It solves scope resolution issues related to using arguments within a with block on an object that has an arguments member, such as Math.

APPENDIX D: RESOLUTION HISTORY

D.1 January 15, 1997

D.1.1 White Space
Updated the White Space section to include form feed and vertical tab as white space.

D.1.2 Keywords
Updated the Keywords section to exclude those keywords related to proposed extensions. Also updated this section to include the delete keyword which was missing.

D.1.3 Future Reserved Words
Update the Future Reserved Words to only include keywords related to proposed extensions. We decided to remove words that had been only included as future reserved for Java compatibility purposes.

D.1.4 Octal And Hex Escape Sequence Issue
Decided to support octal and hex notation. Since only two hex digits are used with hex notation, many unicode characters cannot be represented this way. Furthermore, we were not sure if the high 128 characters match up with unicode. (Removed open issue at bottom of section String Literals)

The argument against was that these notations are redundant since any character can be represented using the unicode escape sequence. The arguments for were that hex and octal notation are convenient and simple and also that there is a language tradition to be upheld.

D.1.5 ToPrimitive
Removed the erroneous note stating that errors are never generated as a result of calling ToPrimitive in the ToPrimitive section.

D.1.6 Hex in ToNumber
We decided to allow hex in ToNumber but not octal. Looking at it from the user input source point of view, we decided that it was reasonable to use hex but not octal since it might be common to include leading zeros in a user input field. Furthermore we did not believe that the ability to use octal in data entry was desirable. (Removed open issue at the bottom of 5.3.1 ToNumber Applied to the String Type)

D.1.7 Attributes of Declared Functions and Built-in Objects
We decided that built-in objects will have attributes { DontEnum } and that variables declared in global code will have empty attributes. (Updated the 6.1.1 Global Object section)
D.1.8 The Grouping Operator

We decided that the grouping operator would return the result of GetValue() so that the result is never of type reference. (Updated the The Grouping Operator section and removed the open issue at the bottom of this section)

D.1.9 Prefix Increment and Decrement Operators

We decided to not to perform GetValue to the return value and thus leave the algorithm as is. (removed the open issue at the bottom of Prefix Increment and Decrement Operators)

D.1.10 Unary Plus

We decided to leave the algorithm for unary plus alone and continue to call GetValue() and ToNumber() after evaluating the unary expression which guarantees a numeric result as opposed to only evaluating the unary expression which would not guarantee a numeric result. (Updated the Unary + and - Operators section)

D.1.11 Multiplicative Operators

Updated step nine in the Multiplicative Operators section to refer to three new sections 7.41, 7.42 and 7.43 which define the behavior of *, / and %.

D.1.12 Additive Operators

Updated step 11 in 7.5.1 and step 10 in 7.5.2 to refer to a new section 7.5.3 which define the behavior of + and -.

D.1.13 Left Shift Operator

We decided to leave the algorithm for left shift as is, which converts the left operand using ToInt32 rather than ToUint32. Although an unsigned conversion might be arguably preferred, we decided to continue to convert to signed, as we can always add a new operator (<<<) to accomplish an unsigned shift. (Removed the open issue at the bottom of The Left Shift Operator (<<) section)

D.1.14 Binary Bitwise Operators

We decided to leave the algorithm for the binary bitwise operators as is, which uses signed conversion on the GetValue of its operands. (Removed the open issue at the bottom of Binary Bitwise Operators)

D.1.15 Conditional Operator (? : )

We decided to leave the algorithm for the conditional operator as is, which performs a GetValue on the result before returning. Current implementations do not do this. (Removed the open issue at the bottom of Conditional Operator (? : ) section)

D.1.16 Simple Assignment

We decided to leave the algorithm for simple assignment as is. (Removed the open issue at the bottom of Simple Assignment ( = ) section)

D.1.17 The for..in Statement

We decided to impose no restrictions on Expression1. (Removed the first open issue at the bottom of The for..in Statement section)
D.1.18 The return Statement

We decided to not generate an error if one return statement in a function returns a value and another return in the same function does not return a value. (Removed the first open issue at the bottom of the return Statement) The second issue at the bottom of this section has been moved to The CV of CharacterEscapeSequence :: \ NonEscapeCharacter is the CV of the NonEscapeCharacter.

- The CV of NonEscapeCharacter :: SourceCharacter but not SingleEscapeCharacter or OctalDigit or x or u or LineTerminator is the SourceCharacter character itself.
- The CV of HexEscapeSequence :: \x HexDigit HexDigit is the Unicode character whose code is (16 times the MV of the first HexDigit) plus the MV of the second HexDigit.
- The CV of OctalEscapeSequence :: \ OctalDigit is the Unicode character whose code is the MV of the OctalDigit.
- The CV of OctalEscapeSequence :: \ OctalDigit OctalDigit is the Unicode character whose code is (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.
- The CV of OctalEscapeSequence :: \ ZeroToThree OctalDigit OctalDigit is the Unicode character whose code is (64 (that is, 8^2) times the MV of the ZeroToThree) plus (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.
- The MV of ZeroToThree :: 0 is positive zero.
- The MV of ZeroToThree :: 1 is 1.
- The MV of ZeroToThree :: 2 is 2.
- The MV of ZeroToThree :: 3 is 3.
- The CV of UnicodeEscapeSequence :: \ u HexDigit HexDigit HexDigit HexDigit is the Unicode character whose code is (4096 (that is, 16^3) times the MV of the first HexDigit) plus (256 (that is, 16^2) times the MV of the second HexDigit) plus (16 times the MV of the third HexDigit) plus the MV of the fourth HexDigit.

Note that a LineTerminator character cannot appear in a string literal, even if preceded by a backslash \.

The correct way to cause a line terminator character to be part of the string value of a string literal is to use an escape sequence such as \n or \u000A.

Automatic Semicolon Insertion (Automatic Semicolon Insertion)

D.1.19 New Proposed Extensions

Sections B.10 Preprocessor and B.11 The do..while Statement and B.12 Binary Object were added.

D.2 January 24, 1997

D.2.1 End Of Source

Updated SourceCharacter ::

any Unicode character

End Of SourceSourceCharacter ::

any Unicode character

End Of Source section to describe the end of source token as logical rather than physical \u0000 since strings may contain embedded \u0000 characters.

D.2.2 Future Reserved Words

Updated Future Reserved Words section to include the word do and removed the footnotes indicating the origin of the proposed keywords.
D.2.3 White Space

Updated White Space section. Updated the lexical production for SimpleWhiteSpace to include \<VT> and \<FF> (already mentioned in the white table above).

D.2.4 Comments

Added new issue to 3.2 regarding nested comments.

D.2.5 Identifiers

Updated section 3.3.2 to correctly state what is an allowable first character in an identifier.

D.2.6 Numeric Literals

Updated section 3.3.4.3 Numeric Literals to disallow leading zeros in floating point literals.

D.2.7 String Literals

Updated the table describing the set of character escape characters in section String Literals, to include a new column indicating the unicode value. Also added a new issue to the end of this section.

D.2.8 Automatic Semicolon Insertion

Added two new issues to the end of The CV of CharacterEscapeSequence :: \ NonEscapeCharacter is the CV of the NonEscapeCharacter.

- The CV of NonEscapeCharacter :: SourceCharacter but not SingleEscapeCharacter or OctalDigit or x or u or LineTerminator is the SourceCharacter character itself.
- The CV of HexEscapeSequence :: \x HexDigit HexDigit is the Unicode character whose code is (16 times the MV of the first HexDigit) plus the MV of the second HexDigit.
- The CV of OctalEscapeSequence :: \ OctalDigit is the Unicode character whose code is the MV of the OctalDigit.
- The CV of OctalEscapeSequence :: \ OctalDigit OctalDigit is the Unicode character whose code is (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.
- The CV of OctalEscapeSequence :: \ ZeroToThree OctalDigit OctalDigit is the Unicode character whose code is (64 (that is, 8^3) times the MV of the ZeroToThree OctalDigit) plus (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.
- The MV of ZeroToThree :: 0 is positive zero.
- The MV of ZeroToThree :: 1 is 1.
- The MV of ZeroToThree :: 2 is 2.
- The MV of ZeroToThree :: 3 is 3.
- The CV of UnicodeEscapeSequence :: \u HexDigit HexDigit HexDigit HexDigit is the Unicode character whose code is (4096 (that is, 16^4) times the MV of the first HexDigit) plus (256 (that is, 16^2) times the MV of the second HexDigit) plus (16 times the MV of the third HexDigit) plus the MV of the fourth HexDigit.

Note that a LineTerminator character cannot appear in a string literal, even if preceded by a backslash .\.

The correct way to cause a line terminator character to be part of the string value of a string literal is to use an escape sequence such as \n or \u000A.

Automatic Semicolon Insertion Automatic-Semicolon-Insertion.
D.2.9 Property Attributes

Renamed \textit{Permanent} to \textit{DontDelete} in the property attributes table in the \textit{Property Attributes} section.

D.2.10 ToPrimitive

Reworded section \textit{ToPrimitive} to better describe the optional hint \textit{PreferredType}.

D.2.11 ToNumber

Updated section \textit{ToNumber}. Added Hint Number in call to ToPrimitive. Also added new issue to the end of this section.

D.2.12 White Space

Updated section \textit{ToNumber Applied to the String Type} Updated the lexical production for SimpleWhiteSpace to include \textlangle VT\textrangle and \textlangle FF\textrangle.

D.2.13 ToNumber Applied to the String Type

Updated section 5.3.1, ToNumber Applied to the String Type. Reworked lexical productions to be similar to those used in section, \textit{Numeric Literals}.

\textit{Numeric Literals}. The difference between string numeric literals and numeric literals is that string numeric literals do not allow octal notation and do allow leading zeros.

D.2.14 ToString

Updated section \textit{ToString}. Added Hint String in call to ToPrimitive.

D.2.15 Postfix Increment and Decrement Operators

Updated section \textit{Postfix Increment and Decrement Operators}. Updated the algorithm to return Result(3) (the result of converting ToNumber), rather than (Result(2).

D.2.16 The \texttt{typeof} operator

Added a new issue at the end of section \texttt{typeof Operator}.

D.2.17 Prefix Increment and Decrement Operators

Removed extraneous calls to ToPrimitive from the algorithm in section \texttt{Prefix Increment and Decrement Operators}.

D.2.18 Multiplicative Operators

Remove step 7 in the algorithm in section 7.4 (either operand NaN) and added a new rule to 7.4.1 and 7.4.2 to reiterate what was in the old step.

D.2.19 The Subtraction Operator

Removed extraneous calls to ToPrimitive from the algorithm in section 7.5.2.

D.2.20 The Subtraction Operator

Remove the old step 9 in the algorithm in section 7.5.2 (either operand NaN) and added a new rule to section 7.5.3 to reiterate what was in the old step.
D.2.21 Applying the Additive Operators (+, −)
Update the last rule in section 7.5.3 to clearly state that operands mentioned in the final sentence must be numeric.

D.2.22 Equality Operators
Moved the Semantic discussion at the beginning of 7.8 to the discussion section at the end of 7.8.

D.2.23 ToPrimitive Usage
Added issue at the end of sections 7.5.1 and 7.7.

D.2.24 Binary Logical Operators
Added issue at the end of 7.10.

D.3 January 31, 1997

D.3.1 MultiLineComment
Updated the lexical production MultiLineComment in section LineEnd ::
   LineTerminator
   <EOS>
CommentsLineEnd ::
   LineTerminator
   <EOS>
Comments, to allow empty multi-line comments. Also removed the issue at the end of this section regarding nested multi-line comments. The MultiLineComment production continues to disallow multi-line comments.

D.3.2 String Literals
Removed open issue at the end of section String Literals String Literals which stated that the maximum string constant supported must be at least 32000 characters long.

D.3.3 Automatic Semicolon Insertion
Updated section The CV of CharacterEscapeSequence :: \ NonEscapeCharacter is the CV of the NonEscapeCharacter:
   • The CV of NonEscapeCharacter :: SourceCharacter but not SingleEscapeCharacter or OctalDigit or \x or \u or LineTerminator is the SourceCharacter character itself.
   • The CV of HexEscapeSequence :: \x HexDigit HexDigit is the Unicode character whose code is (16 times the MV of the first HexDigit) plus the MV of the second HexDigit.
   • The CV of OctalEscapeSequence :: \ OctalDigit is the Unicode character whose code is the MV of the OctalDigit.
   • The CV of OctalEscapeSequence :: \ OctalDigit OctalDigit is the Unicode character whose code is (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.
   • The CV of OctalEscapeSequence :: \ ZeroToThree OctalDigit OctalDigit is the Unicode character whose code is (64 (that is, 2^6) times the MV of the ZeroToThree) plus (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.
• The MV of ZeroToThree :: 0 is positive zero.
• The MV of ZeroToThree :: 1 is 1.
• The MV of ZeroToThree :: 2 is 2.
• The MV of ZeroToThree :: 3 is 3.

The CV of UnicodeEscapeSequence :: \u HexDigit HexDigit HexDigit HexDigit is the Unicode character whose code is (4096 (that is, $16^5$) times the MV of the first HexDigit) plus (256 (that is, $16^2$) times the MV of the second HexDigit) plus (16 times the MV of the third HexDigit) plus the MV of the fourth HexDigit.

Note that a LineTerminator character cannot appear in a string literal, even if preceded by a backslash \\.
The correct way to cause a line terminator character to be part of the string value of a string literal is to use an escape sequence such as \n or \u000A.

Automatic Semicolon Insertion, to include rules governing parsing the for statement and dealing with postfix ++ and postfix -- tokens.

D.3.4 The Number Type

Updated the description in section The Number Type.

D.3.5 Put with Explicit Access Mode

Update section 4.5.2.3, Put with Explicit Access Mode to include looking in the prototype object for access violations.

D.3.6 Put with Implicit Access Mode

Update section 4.5.2.4, Put with Implicit Access Mode to include looking in the prototype object for access violations.

D.3.7 The String type

Updated the description in section 4.6, The String Type.

D.3.8 ToNumber

Updated section 5.3, ToNumber to return a NaN for an input type of Null.

D.3.9 ToNumber Applied to the String Type

Updated the lexical production for SimpleWhiteSpace in section 5.3.1 to include <CR> and <LF>. Also updated the lexical productions StrFloatingPointLiteral and StrIntegerLiteral to allow signs.

D.3.10 ToInt32

Updated description in section 5.5, ToInt32: (signed 32 bit integer) to tentatively use Guy’s Conversion modulo $2^{32}$ algorithm.

D.3.11 ToUint32

Updated description in section ToUint32: (unsigned 32 bit integer) ToUint32: (unsigned 32 bit integer) to tentatively use Guy’s Conversion modulo $2^{32}$ algorithm.

D.3.12 Execution Contexts (Variables)

Section 6 (Variables) replaced by new section (Execution Contexts).
D.3.13 Function Calls
Swapped steps 2 and 3 in section 7.2.4, Function Calls.

D.3.14 The typeof Operator
Updated the table in section typeof Operator to specify the result when the input type is an external object. Removed related open issue at the end of this section.

D.3.15 Applying the % Operator
Removed step 7 in the algorithm in section 7.4.(either operand NaN) and added a new rule to 7.4.3 to reiterate what was in the old step.

D.3.16 The Addition Operator (+)
Added the hint Number in the calls to ToPrimitive in section 7.5.1, The Addition Operator (+). Removed related open issue at the end of this section.

D.3.17 Relational Operators
Added the hint Number in the calls to ToPrimitive in section 7.7, Relational Operators. Removed related open issue at the end of this section.

D.3.18 Conditional Operator (?:)
Updated the syntactic production, ConditionalExpression, in section Conditional Operator (?:)

D.3.19 Compound Assignment (op=)
Swapped steps 2 and 3 in section 7.12.2, Compound Assignment (op=)

D.4 FEBRUARY 21, 1997

D.4.1 Unicode Escape Sequences
Rewrote section Unicode to reflect the restriction that non-ASCII Unicode characters may appear only within comments and string literals. Moved the description of Unicode escape sequences to String Literals.

D.4.2 Future Reserved Words
Added import and super to table in Future Reserved Words.

D.4.3 Automatic Semicolon Insertion
Rewrote the rules for semicolon insertion in section The CV of CharacterEscapeSequence :: \ NonEscapeCharacter is the CV of the NonEscapeCharacter.
- The CV of NonEscapeCharacter :: SourceCharacter but not SingleEscapeCharacter or OctalDigit or x or u or LineTerminator is the SourceCharacter character itself.
- The CV of HexEscapeSequence :: \x HexDigit HexDigit is the Unicode character whose code is (16 times the MV of the first HexDigit) plus the MV of the second HexDigit.
- The CV of OctalEscapeSequence :: \ OctalDigit is the Unicode character whose code is the MV of the OctalDigit.
The CV of OctalEscapeSequence :: \ OctalDigit OctalDigit is the Unicode character whose code is (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.

The CV of OctalEscapeSequence :: \ ZeroToThree OctalDigit OctalDigit is the Unicode character whose code is (64 (that is, $8^2$) times the MV of the ZeroToThree) plus (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.

The MV of ZeroToThree :: 0 is positive zero.
The MV of ZeroToThree :: 1 is 1.
The MV of ZeroToThree :: 2 is 2.
The MV of ZeroToThree :: 3 is 3.

The CV of UnicodeEscapeSequence :: \u HexDigit HexDigit HexDigit HexDigit is the Unicode character whose code is (4096 (that is, $16^3$) times the MV of the first HexDigit) plus (256 (that is, $16^2$)) times the MV of the second HexDigit) plus (16 times the MV of the third HexDigit) plus the MV of the fourth HexDigit.

Note that a LineTerminator character cannot appear in a string literal, even if preceded by a backslash \.

The correct way to cause a line terminator character to be part of the string value of a string literal is to use an escape sequence such as \n or \u000A.

Automatic Semicolon Insertion

To incorporate the rule that a semicolon is not inserted if it would be treated as an empty statement. Also, broke out the empty statement as a separate kind of statement for expository purposes in section Empty Statement.

D.4.4 The Number Type

Corrected formatting of formulae in section The Number Type.

D.4.5 NotImplicit and NotExplicit Property Attributes Deleted

The NotImplicit and NotExplicit property attributes were deleted from the table in section Property Attributes. Many changes throughout the rest of chapter 4 to reflect this deletion. Also, the [[TestPutExplicit]] helper method was renamed [[CanPut]].

D.4.6 ToInt32 and ToUint32

Corrected formatting of formulae in section ToInt32: (signed 32 bit integer) and section ToUint32: (unsigned 32 bit integer). Also, change the discarding of the fractional part to truncate toward zero rather than using a simple floor operation.

Correct an error in the descriptions by adding a new step 4 to each one, which makes sure that if the input is negative zero, the output is positive zero.

D.4.7 Grouping Operator

Delete step 2 from section The Grouping Operator. Parentheses no longer force dereferencing.

D.4.8 Shift Expressions

Correct the grammar for ShiftExpression by adding AdditiveExpression as an alternative in section Bitwise Shift Operators.

D.4.9 Conversion Rules for Relational Operators

Updated description in section Relational Operators so that lexicographic string ordering is used only if both operands become strings when converted to primitive type; if one is a string and one is a number, then numeric ordering is used. Thus relational operators differ from the + operator, which, if one operand is a string and one is a number, performs string concatenation rather than addition.
D.4.10 && and || Semantics

Updated description in section Binary Logical Operators so that && and || have PERL-like semantics; that is, the result of 1 || 2 is 1, not true, and the result of 0 || “Hello” is “Hello”.

D.4.11 Conditional Operator

Updated section Conditional Operator (?::) to reflect the change that the second and third subexpressions should each be AssignmentExpression.

D.4.12 Assignment Operators

Updated section Assignment Operators to reflect the change that the left-hand side of an assignment should be a PostfixExpression. Also change two occurrences in subsections of SetVal to PutValue.

D.4.13 Syntax of Class Statement

Updated section B.1 The Class Statement to allow the parentheses in a class declaration to be optional.

D.4.14 Syntax of Try Statement

Updated section B.2.1 The try Statement to require the body of a catch or finally clause to be a Block.

D.5 February 27, 1997

D.5.1 Grammar Notation

Big rewrite of section Syntactic and Lexical Grammars to make the description of grammar notation more detailed and rigorous. Is this okay? (Much of the text was borrowed, in form at least, from the Java Language Specification.) The notation is still a bit inconsistent throughout the document (example: “except” versus “but not”), and should be made consistent within itself and with section Syntactic and Lexical Grammars.

Also decided to call out the grammar in Chapter 5 as a separate grammar and use triple colons on its productions.

Restructured some of the grammar in Chapter 3 to make it a bit more readable. Is this okay?

D.5.2 End of Medium Character Is No Longer WhiteSpace

Deleted character u0019 (End of Medium) from the table in section White Space, and deleted <EOM> as an alternative for SimpleWhiteSpace in that same section. Also deleted <EOM> as an alternative for StrWhiteSpaceChar in section ToNumber Applied to the String Type. These changes reflect the decision that neither \u0019 (End of Medium, mistakenly also referred to in previous drafts of this document as ^Z) nor \u001A (Substitute, which really is ^Z) shall be considered whitespace in an ECMAScript program. It is expected that host environments will filter any ^Z character that might occur at the end of the host environment’s representation of an ECMAScript program.

D.5.3 Meaning of Null Literal

Added to section Null Literals a discussion of the meaning of a null literal.

D.5.4 Meaning of Boolean Literals

Added to section Semantics
The value of the null literal `nulltrue` is the sole value of the Nnull type, namely `null`.

Boolean Literals Semantics

The value of the null literal `true` is the sole value of the null type, namely `null`.

Boolean Literals a discussion of the meaning of a boolean literal.

D.5.5 Meaning of Numeric Literals

Added to section

Numeric Literals

Numeric Literals a discussion of the meaning of a numeric literal. It does not yet address the restriction to 19 significant digits. Is this the style of description we want?

D.5.6 Automatic Semicolon Insertion

Updated description of automatic semicolon insertion in section `The CV of CharacterEscapeSequence :: \ NonEscapeCharacter` is the CV of the NonEscapeCharacter.

- The CV of NonEscapeCharacter :: SourceCharacter but not SingleEscapeCharacter or OctalDigit or `x` or `u` or LineTerminator is the SourceCharacter character itself.
- The CV of HexEscapeSequence :: \x HexDigit HexDigit is the Unicode character whose code is (16 times the MV of the first HexDigit) plus the MV of the second HexDigit.
- The CV of OctalEscapeSequence :: \ OctalDigit is the Unicode character whose code is the MV of the OctalDigit.
- The CV of OctalEscapeSequence :: \ OctalDigit OctalDigit is the Unicode character whose code is (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.
- The CV of OctalEscapeSequence :: \ ZeroToThree OctalDigit OctalDigit is the Unicode character whose code is (64 (that is, 8^2) times the MV of the ZeroToThree) plus (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.
- The MV of ZeroToThree :: 0 is positive zero.
- The MV of ZeroToThree :: 1 is 1.
- The MV of ZeroToThree :: 2 is 2.
- The MV of ZeroToThree :: 3 is 3.
- The CV of UnicodeEscapeSequence :: \u HexDigit HexDigit HexDigit HexDigit is the Unicode character whose code is (4096 (that is, 16^3) times the MV of the first HexDigit) plus (256 (that is, 16^2) times the MV of the second HexDigit) plus (16 times the MV of the third HexDigit) plus the MV of the fourth HexDigit.

Note that a LineTerminator character cannot appear in a string literal, even if preceded by a backslash \. The correct way to cause a line terminator character to be part of the string value of a string literal is to use an escape sequence such as `\n` or `\u000A`.

Automatic Semicolon Insertion. Systematically replaced the word “injected” with “inserted”. Invented a new theory of “restricted productions” to explain in a general way why the parser inserts semicolons in places where there would otherwise be a valid parse without a semicolon. Added more examples and advice. Also modified productions in sections Postfix Expressions to indicate the restrictions explicitly.

D.5.7 The Number Type

Updated section `The Number Type` to provide explanations of those large numbers as sums and differences of powers of two.
D.5.8 ToString on Numbers

Updated section on `ToString Applied to the Number Type` have a draft specification of how this conversion ought to be done. This needs to be reviewed. This version requires that, when the number has a nonzero fractional part, the output must be correctly rounded and produce no more digits than necessary for the fractional part. Added a bibliographic reference to the paper and code of David M. Gay on this subject.

D.5.9 New Operator

Updated description in section `The new Operator` to describe the case where no argument list is provided. This needs to be reviewed.

D.5.10 Delete Operator

Updated description in section `The delete Operator` to reflect decision that this operator shall return a boolean value; the value `true` indicates that, after the operation, the object is guaranteed not to have the specified property.

D.5.11 == Semantics

Updated section on `Equality Operators` so that (a) `null` and `undefined` are considered equal, and (b) when a number meets a string, the number is converted to a string and then string equality is used.

D.5.12 && and || Semantics

Updated description in section `Binary Logical Operators` to delete step 7 for each operator (the result of this step was no longer used).

D.5.13 Separate Productions for Continue, Break, Return

To make certain kinds of cross-reference in the document simpler, I broke out the continue, break, and return statements into separate grammatical productions, eliminating the production for `ControlFlowStatement` (which was something of a misnomer anyway, and other statements also result in (structured) control flow).

D.5.14 Dead Code Is Not Protected from Compile-Time Analysis

 Added text to chapter 12 (Errors).

D.6 MARCH 6, 1997

D.6.1 Reformatted the Entire Document

I order to make future revisions easier and to take better advantage of the desktop-publishing capabilities of Word, the entire document was reformatted using some newly defined Word styles. Heading numbering was turned on to facilitate automatic numbering of headings in the main text (sections of the appendices are still numbered manually, using new styles Appendix Heading 1, Appendix Heading 2, and Appendix Heading 3). A new style Algorithm is used for algorithmic steps; in some cases, the last step should be styled with AlgorithmLast to provide extra vertical space after the last step.

Added a style called MathSpecialCase (generates bullet lists for now).

The title page now uses styles Title and Subtitle, which were modified to use appropriate fonts and paragraph spacing.

Extraneous tab characters and multiple spaces were deleted from all headings.
The paragraph spacing of Normal, the various headings, Algorithm, AlgorithmLast, SyntaxRule, and SyntaxDefinition were adjusted so that the correct vertical space is inserted automatically. All blank paragraphs in the document were deleted.

The index and all index entries were deleted. Sorry, but they were somehow interfering with other formatting, and the index entries were terribly incomplete anyway. If we have time to do a good index, entries can be added semi-systematically.

The document was divided into three of what Word calls “sections” so that the pages of the Table of Contents could be numbered with the customary roman numerals, with the main text starting on page 1.

All the revisions listed in this item were accepted and the change bars reset before the following items were entered, so that all the changes of this item would not clutter the manuscript.

D.6.2 Designed a Section Outline for Chapter 11

Filled in nearly all necessary section headings for Chapter 1 for describing Object, Function, Array, String, Boolean, Number, and Math and all their properties and methods. Added a fair amount of boilerplate text.

D.6.3 Defined Math Functions

Added complete definitions for all properties in the Math object, following the example of C9X for the treatment of IEEE 754 special cases.

D.7 March 10, 1997

D.7.1 Added Definition of “The Number Value for x”

In section 4.4, the phrase “the number value for x” is now defined. It encapsulates the entire IEEE 754 process for converting any nonzero mathematical value to a representable value by using round-to-nearest mode. This phrase is of great use in Chapter 11 and elsewhere.

Also corrected two typos in this section: −1073 replaced by −1074, and 2^53 replaced by 2^52.

D.7.2 atan and atan2 May Use Implementation-Dependent Values for π, etc.

It was decided at the phone meeting that when Math.atan, for example, is supposed to return π/2, it need not return exactly one-half the initial value of Math.pi but may produce an approximation. The motivation is to allow implementors the use of whatever C math library is present on the hardware platform at hand, whether or not it conforms to the high quality standards of, for example, the C9X proposal.

D.7.3 Improved Discussion of Input Stream for Syntactic Grammar

Text added to section 1.1 to better explain the handling of whitespace, comments, and line terminators, and the fact that line terminators become part of the input stream for the syntactic grammar. Also corrected a type in section 1.1.5 where the phrase “[no LineTerminator here]” had been inadvertently omitted.

D.7.4 Improved Treatment of LineTerminator in Lexical Grammar

Eliminated the mythical <EOS> character. As a result, LineEnd is not needed either. The trick is not to include LineEnd (or LineTerminator) as part of the grammar of a single-line comment. This works out better, because a single-line comment still runs to the end of the line (as dictated by the longest-token-possible rule), but it doesn’t swallow the LineTerminator, so it doesn’t affect automatic semicolon insertion. (That the previous production did swallow the LineTerminator was thus a bug.)

The section on whitespace has been divided into two sections, one on WhiteSpace (formerly called SimpleWhiteSpace) and one on Line Terminators.
THIS CHANGE REQUIRES REVIEW.

D.7.5 Clarify Behavior of Unicode Escape Sequences

In Chapter 2, clarify that a Unicode escape sequence such as \u000D does not produce a carriage return that could end a single-line comment, for example.

D.7.6 Add Careful Description of the String Value of a String Literal

In imitation of the text already present describing the value of a numeric literal, text was added to section 3.7.4 to describe carefully the exact sequence of characters represented by a string literal. In the process, missing productions for DoubleStringCharacters and SingleStringCharacters were added, and the redundant definitions of HexDigit and OctalDigit were removed. Also dealt with an open issue by emphasizing that a LineTerminator may not appear within a string literal.

D.7.7 Description of Identifiers Reworded

Improvements to the wording in section 3.5. Also repaired a typo (capital I replaced by lowercase i).

D.7.8 Table of Punctuators Corrected

Underscore replaced by + operator in table in section 3.6.

D.7.9 Improved Descriptions of ToInt32 and ToUint32

Step 5 of the algorithms in sections 5.5 and 5.6 have been clarified to use a mathematical description rather than fragments of code.

D.7.10 Changes to ToString Applied to the Number Type

See section 5.7.1. Negative zero now produces "0", not "-0". Integers less than 10^{20} shall print without decimal points. Values less than 1 but not less than 10^{-6} will not require scientific notation.

D.7.11 Revised Syntax for NewExpression and MemberExpression

Made the changes to section 7.2 as suggested by Shon, eliminating NewCallExpression and providing a pleasing symmetry in which the number of new operators can exceed or fall short of the number of argument lists.

D.7.12 Clarify Multiplicative and Additive Operators

In section 7.4.1, describe the multiplication of infinity by infinity.
In section 7.4.1, describe the division of infinity by zero.
In section 7.4.1, better describe the remainder of a zero by a finite number.
In section 7.5, better describe the sum of two zeros and the sum of finite numbers of same magnitude and opposite sign.

D.7.13 Addition Operator No Longer Gives Hint Number

When the addition operator + calls ToPrimitive, it no longer gives hint Number. Note that all built-in objects respond to ToPrimitive without a hint as if hint Number were given, so this change affects only external objects.

D.7.14 Correct Description of Relational Operators

Miscellaneous small corrections.
D.7.15 Assignment Operator LHS Must Be PostfixExpression

Change four occurrences of UnaryExpression to PostfixExpression in section 7.12.

D.7.16 Changes to For-in Loops

Without var, the expression before in must be a PostfixExpression (as for an assignment).
With var, an optional Initializer is permitted after the Identifier.
A For-In loop enumerates not only properties of the given object itself, but also properties of its prototype, and so on, recursively.
ISSUE: Are shadowed properties of the prototype enumerated?

D.7.17 Break and Continue Must Occur within While or For Loop

Added text to sections 8.6 and 8.7 to require break and continue to appear within loop statements.
APPENDIX E: LALR(1) SYNTACTIC GRAMMAR

Issue: To be supplied?
