ECMAScript Internationalization API Specification

1 Scope

This Standard defines the application programming interface for ECMAScript objects that support programs that need to adapt to the linguistic and cultural conventions used by different human languages and countries.

2 Conformance

A conforming implementation of the ECMAScript Internationalization API must conform to the ECMAScript Language Specification, 5.1 edition or successor, and must provide and support all the objects, properties, functions, and program semantics described in this specification.

A conforming implementation of the ECMAScript Internationalization API is permitted to provide additional objects, properties, and functions beyond those described in this specification. In particular, a conforming implementation of the ECMAScript Internationalization API is permitted to provide properties not described in this specification, and values for those properties, for objects that are described in this specification. A conforming implementation is not permitted to add optional arguments to the functions defined in this specification.

3 Normative References

The following referenced documents are required for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ECMA-262, ECMAScript Language Specification, 5.1 edition or successor

ISO/IEC 10646:2003: Information Technology — Universal Multiple-Octet Coded Character Set (UCS) plus Amendment 1:2005, plus additional amendments and corrigenda, or successor

ISO 4217:2008, Codes for the representation of currencies and funds, or successor

The Unicode Standard, Version 4.1.0, or successor

Unicode Technical Standard 35, Unicode Locale Data Markup Language, version 2.0.1 or successor

IETF BCP 47:
- RFC 5646, Tags for Identifying Languages, or successor
- RFC 4647, Matching of Language Tags, or successor

IETF RFC 6067, BCP 47 Extension U, or successor

Throughout this document, the phrase “ES5, x”, where x is a sequence of numbers separated by periods, may be used as shorthand for “ECMAScript Language Specification, 5.1 edition, subclause x”.

4 Overview

This section contains a non-normative overview of the ECMAScript Internationalization API.

4.1 Internationalization, Localization, and Globalization

Internationalization of software means designing it such that it supports or can be easily adapted to support the needs of users speaking different languages and having different cultural expectations, and enables
worldwide communication between them. Localization then is the actual adaptation to a specific language and culture. Globalization of software is commonly understood to be the combination of internationalization and localization. Globalization starts at the lowest level by using a text representation that supports all languages in the world, and using standard identifiers to identify languages, countries, time zones, and other relevant parameters. It continues with using a user interface language and data presentation that the user understands, and finally often requires product-specific adaptations to the user’s language, culture, and environment.

The ECMAScript Language Specification lays the foundation by using Unicode for text representation and by providing a few language-sensitive functions, but gives applications little control over the behavior of these functions. The ECMAScript Internationalization API builds on this by providing a set of customizable language-sensitive functionality. The API is useful even for applications that themselves are not internationalized, as even applications targeting only one language and one region need to properly support that one language and region. However, the API also enables applications that support multiple languages and regions, even concurrently, as may be needed in server environments.

4.2 API Overview

The ECMAScript Internationalization API is designed to complement the ECMAScript Language Specification by providing key language-sensitive functionality. The API can be added to an implementation of the ECMAScript Language Specification, 5.1 edition or successor.

The ECMAScript Internationalization API provides three key pieces of language-sensitive functionality that are required in most applications: String comparison (collation), number formatting, and date and time formatting. While the ECMAScript Language Specification provides functions for this basic functionality (String.prototype.localeCompare, Number.prototype.toLocaleString, Date.prototype.toLocaleString, Date.prototype.toLocaleDateString, and Date.prototype.toLocaleTimeString), it leaves the actual behavior of these functions largely up to implementation to define. The Internationalization API Specification provides additional functionality, control over the language and over details of the behavior to be used, and a more complete specification of required functionality.

Applications can use the API in two ways:

1. Directly, by using the constructors Collator, NumberFormat, or DateTimeFormat to construct an object, specifying a list of preferred languages and options to configure the behavior of the resulting object. The object then provides a main function (compare or format), which can be called repeatedly. It also provides a resolvedOptions function, which the application can use to find out the exact configuration of the object.

2. Indirectly, by using the functions of the ECMAScript Language Specification mentioned above, which are respecified in this specification to accept the same arguments as the Collator, NumberFormat, and DateTimeFormat constructors and produce the same results as their compare or format methods.

To support the handling of BCP 47 language tags, LocaleList objects assist with validation and canonicalization of these tags and negotiation against the available locales in an implementation.

The Intl object is used to package all functionality defined in the ECMAScript Internationalization API to avoid name collisions.

4.3 Implementation Dependencies

Due to the nature of internationalization, the API specification has to leave several details implementation dependent:

- The set of locales that an implementation supports with adequate localizations: Linguists estimate the number of human languages to around 6000, and the more widely spoken ones have variations based on regions or other parameters. Even large locale data collections, such as the Common Locale Data Repository, cover only a subset of this large set. Implementations targeting resource-constrained devices may have to further reduce the subset.

5 Notational Conventions

This standard uses a subset of the notational conventions of the ECMAScript Language Specification, 5.1 edition:

- Algorithm conventions, including the use of abstract operations, as described in §5.2.
- Internal properties, as described in §5.8.2.
- The List specification type, as described in §5.8.

NOTE As described in the ECMAScript Language Specification, algorithms are used to precisely specify the required semantics of ECMAScript constructs, but are not intended to imply the use of any specific implementation technique. Internal properties are used to define the semantics of object values, but are not part of the API. They are defined purely for expository purposes. An implementation of the API must behave as if it produced and operated upon internal properties in the manner described here.

In addition, this standard uses variable-named internal properties: The notation "[[<variable>]]" denotes an internal property whose name is given by the variable, which must have a String value.

EXAMPLE If a variable a has the value "a", then [[a]] denotes the [a] internal property.

6 Identification of Locales, Time Zones, and Currencies

This clause describes the String values used in the ECMAScript Internationalization API to identify locales, currencies, and time zones.

6.1 Case Sensitivity and Case Mapping

The String values used to identify locales, currencies, and time zones are interpreted in a case-insensitive manner, treating the Unicode Basic Latin characters "A" to "Z" (U+0041 to U+005A) as equivalent to the corresponding Basic Latin characters "a" to "z" (U+0061 to U+007A). No other case folding equivalences are applied. When mapping to upper case, a mapping shall be used that maps characters in the range "a" to "z" (U+0061 to U+007A) to the corresponding characters in the range "A" to "Z" (U+0041 to U+005A) and maps no other characters to the latter range.

EXAMPLES "b" (U+0062) must not match or be mapped to "SS" (U+0053, U+0053). "v" (U+0076) must not match or be mapped to "V" (U+0056).

6.2 Language Tags

The ECMAScript Internationalization API identifies locales using language tags as defined by IETF BCP 47 (RFCs 5646 and 4647 or their successors), which may include extensions such as those registered through RFC 6067. Their canonical form is specified in RFC 5646 section 4.5 or its successor.
The IsWellFormedCurrencyCode abstract operation verifies that the currency argument (which must be a String value) represents a well-formed BCP 47 currency tag as specified in RFC 5646 section 2.1, or successor. It returns true if a currency can be generated from the ABNF grammar in that section, starting with CurrencyTag, false otherwise. Terminal value characters in the grammar are interpreted as the Unicode equivalents of the ASCII octet values given.

6.2.2 IsWellFormedLanguageTag(locale)

The IsWellFormedLanguageTag abstract operation verifies that the locale argument (which must be a String value) represents a well-formed BCP 47 language tag as specified in RFC 5646 section 2.1, or successor. It returns true if the locale can be generated from the ABNF grammar in that section, starting with LanguageTag, false otherwise. Terminal value characters in the grammar are interpreted as the Unicode equivalents of the ASCII octet values given.

6.2.3 CanonicalizeLanguageTag (locale)

The CanonicalizeLanguageTag abstract operation returns the canonical and case-regularized form of the locale argument (which must be a String value that is a well-formed BCP 47 language tag as verified by the IsWellFormedLanguageTag abstract operation). It takes the steps specified in RFC 5646 section 4.5, or successor, to bring the language tag into canonical form, and to regularize the case of the subtags, but does not take the steps to bring a language tag into "extlang form" and to reorder variant subtags.

The specifications for extensions to BCP 47 language tags, as such as RFC 6067, may include canonicalization rules for the extension subtag sequences they define that go beyond the canonicalization rules of RFC 5646 section 4.5. Implementations are allowed, but not required, to apply these additional rules.

6.2.4 DefaultLocale ()

The DefaultLocale abstract operation returns a String value representing the well-formed (6.2.2) and canonicalized (6.2.3) BCP 47 language tag for the host environment's current locale.

6.3 Currency Codes

The ECMAScript Internationalization API identifies currencies using 3-letter currency codes as defined by ISO 4217. Their canonical form is upper case.

All well-formed 3-letter ISO 4217 currency codes are allowed. However, the set of combinations of currency code and language tag for which localized currency symbols are available is implementation dependent. Where a localized currency symbol is not available, the ISO 4217 currency code is used for formatting.

6.3.1 IsWellFormedCurrencyCode (currency)

The IsWellFormedCurrencyCode abstract operation verifies that the currency argument (which must be a String value) represents a well-formed 3-letter ISO currency code. The following steps are taken:

1. Let normalized be the result of mapping c to upper case as described in 6.1.
2. If the string length of normalized is not 3, return false.
3. If normalized contains any character that is not in the range "A" to "Z" (U+0041 to U+005A), return false.
4. Return true.

The currencyCodeRE expression

```
^\b[A-Z]{3}\b$\n```

should be used to test currency codes. Implementations shall accept all currency codes that match this regular expression.
6.4 Time Zone Names

The ECMA-Script Internationalization API defines a single time zone name, "UTC", which identifies the UTC time zone.

The Intl.DateTimeFormat constructor allows this time zone name; if the time zone is not specified, the host environment's current time zone is used. Implementations shall support UTC and the host environment's current time zone (if different from UTC) in formatting.

7 Requirements for Standard Built-in ECMAScript Objects

Unless otherwise specified in this document, the objects described in this standard are subject to the generic requirements and restrictions specified for standard built-in ECMAScript objects in the ECMAScript Language Specification 5.1 edition, introduction of clause 15, or successor.

8 The Intl Object

The Intl object is a single object that has some named properties, all of which are constructors.

The value of the [[Prototype]] internal property of the Intl object is the built-in Object prototype object specified by the ECMAScript Language Specification.

The Intl object does not have a [[Construct]] internal property; it is not possible to use the Intl object as a constructor with the new operator.

The Intl object does not have a [[Call]] internal property; it is not possible to invoke the Intl object as a function.

8.1 Constructor Properties of the Intl Object

Each of the properties of the Intl object is a constructor. The behavior of these constructors is specified in the following clauses: LocaleList (9), Collator (11), NumberFormat (12), and DateTimeFormat (13).

9 LocaleList Objects

LocaleList objects represent lists of language tags identifying locales. They can be used in two ways:

- To represent a language priority list, as described in RFC 4647, section 2.3, or successor. Algorithms interpreting a LocaleList object in this sense treat the list as unordered.
- To represent a set of locales, such as those supported by an application or by the implementation of an object described in this specification. Algorithms interpreting a LocaleList object in this sense treat the list as unsorted.

LocaleList objects have the properties of a generic array-like object: A length property and other properties whose names are array indices, as defined in ES5, 15.4. The value of the length property is numerically greater than the name of every property inserted during construction whose name is an array index. AsLocaleList objects are extensible, this invariant is not guaranteed to be maintained after construction.

The LocaleList constructor is a property of the Intl object.

9.1 The Intl LocaleList Constructor

9.1.1 Initializing an Object as a LocaleList

The abstract operation InitializeLocaleList accepts the argument localeList, which must be an object, and the optional argument locales. It initializes localeList as a LocaleList object by taking the following steps:

1. If locales is not provided or is undefined, then
   a. Let new be a new List containing the String returned by the DefaultLocale abstract operation.
2. Else
   a. Let seen be a new empty List.
   b. Let O be ToObject(locales).
   c. Let lenValue be the result of calling the [[Get]] internal method of O with the argument "length".
   d. Let len be ToUint32(lenValue).
   e. Let k be 0.
   f. Repeat while k < len
      1. Let Pk be ToString(k).
      2. Let PPresent be the result of calling the [[HasProperty]] internal method of O with argument Pk.
      3. If PPresent is true, then
         1. Let Value be the result of calling the [[Get]] internal method of O with argument Pk.
         2. If the type of Value is not String or Object, then throw a TypeError exception.
         3. Let tag be ToString(Value).
         4. If the result of calling the abstract operation CanonicalizedLanguageTag, passing tag as the argument, is false, then throw a RangeError exception.
         5. Let tag be the result of calling the abstract operation CanonicalizedLanguageTag, passing tag as the argument.
         6. If tag is not an element of seen, then append tag as the last element of seen.
      iv. Increase k by 1.
   1. Let index be 0.
   4. Repeat for each element tag of seen, in list order.
      a. Call the [[DefineOwnProperty]] internal method of locales with arguments ToString(index), Property Descriptor {[[Value]]: tag, [[Writable]]: false, [[Enumerable]]: true, [[Configurable]]: false}, and true.
      b. Increase index by 1.
   5. Call the [[DefineOwnProperty]] internal method of locales with arguments "length", Property Descriptor {[[Value]]: tag, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false}, and true.
   6. Set the [[initializedLocaleList]] internal property of locales to true.

NOTE Non-normative summary: The function interprets the locales argument as an array and copies its elements into locales, validating the elements as well-formed language tags and canonicalizing them, and omitting duplicates. If tags this object as an initialized locale list.

NOTE If an object has been previously initialized using the Intl.LocaleList constructor, and the canonicalization of the previously used locales differs from the canonicalization of the locales used now, then either step 1.a or step 5 will fail.

9.1.2 The Intl.LocaleList Constructor Called as a Function

When Intl.LocaleList is called as a function rather than as a constructor, it accepts the optional argument locales and takes the following steps:

1. If this is the Intl object or undefined, then
   a. Return the result of creating a new object as if by the expression new Intl.LocaleList(locales), where Intl.LocaleList is the standard built-in constructor defined in 9.1.3.
2. Let obj be the result of calling ToObject passing the this value, as the argument.
3. Call the Intl.LocaleList abstract operation with arguments obj and locales.
4. Return obj.

9.1.3 The Intl.LocaleList Constructor Used in a New Expression

When Intl.LocaleList is called as part of a new expression, it is a constructor. It accepts the optional argument locales, and initializes the properties of the newly constructed object by calling the InitializerLocaleList abstract operation (9.1.1), passing the newly constructed object and locales as arguments.

The [[Prototype]] internal property of the newly constructed object is set to the original Intl.LocaleList prototype object, the one that is the value of Intl.LocaleList.prototype (9.2.1).

The [[Extensible]] internal property of the newly constructed object is set to true.
9.2 Properties of the Intl.LocaleList Constructor

Besides the internal properties and the length property (whose value is 1), the Intl.LocaleList constructor has the following properties:

9.2.1 Intl.LocaleList.prototype

The value of Intl.LocaleList.prototype is the built-in Intl.LocaleList prototype object (9.3).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: true, [[Configurable]]: false }.

9.3 Properties of the Intl.LocaleList Prototype Object

The Intl.LocaleList prototype object is itself an Intl.LocaleList instance as specified in 9.1, whose properties are set as if it had been constructed by the expression new Intl.LocaleList([]).

9.3.1 Intl.LocaleList.prototype.constructor

The initial value of Intl.LocaleList.prototype.constructor is the built-in Intl.LocaleList constructor.

9.4 Properties of Intl.LocaleList Instances

Intl.LocaleList instances inherit properties from the Intl.LocaleList prototype object.

Intl.LocaleList instances and other objects that have been successfully initialized as a LocaleList have an [initializedLocaleList] internal property whose value is true.

Intl.LocaleList instances and other objects that have been successfully initialized as a LocaleList also have the following properties.

9.4.1 length

The length property of an Intl.LocaleList object is a data property whose value is the number of array index properties added to the object by the InitializeLocaleList abstract operation.

The length property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

9.4.2 Properties With Array Index Names

A LocaleList object has properties whose names are array indices from 0 to (length - 1). The value of each of these properties is a String value representing a well-formed language tag. The values are unique within a LocaleList object.

These properties initially have the attributes { [[Writable]]: false, [[Enumerable]]: true, [[Configurable]]: false }.

10 Locale and Parameter Negotiation

The constructors for the objects providing locale sensitive services, Collator, NumberFormat, and DateTimeFormat, use a common pattern to negotiate the requests represented by the localeList and options arguments against the actual capabilities of their implementations. The common behavior is described here in terms of internal properties describing the capabilities and of abstract operations using these internal properties.

10.1 Internal Properties of Service Constructors

The constructors Intl.Collator, Intl.NumberFormat, and Intl.DateTimeFormat have the following internal properties:
The Lookup abstract operation takes an availableLocales argument, which must be a LocaleList object representing a BCP 47 language tags priority list, against the locales in availableLocales and determines the best available language to meet the request. The following steps are taken:

1. Let i be 0.
2. Let len be the result of calling the [[Get]] internal method of requestedLocales with argument "length".
3. Let availableLocales be i.

10.2 Abstract Operations

Where the following abstract operations take an availableLocales argument, it must be an object that has been initialized as a LocaleList. It represents a set of locales, the ordering of the locales within availableLocales is irrelevant.

10.2.1 indexOfMatch (availableLocales, locale)

The indexOfMatch abstract operation compares the provided argument locale, which must be a String value with a well-formed and canonicalized BCP 47 language tag, against the locales in availableLocales and returns the index of the best available match. It uses the fallback mechanism of RFC 4647, section 3. The following steps are taken:

1. Let index be the standard built-in function object defined in ES5, 15.4.4.14.
2. Let candidate be locale.
3. Repeat
   a. Let index be the result of calling the [[Call]] internal method of indexOf with availableLocales as the this value and an argument list containing the single item candidate.
   b. If index ≠ -1, then return index.
   c. Let pos be the character index of the last occurrence of "-" (U+002D) within candidate. If that character does not occur, return -1.
   d. If pos ≥ 2 and the character "-" occurs at index pos-2 of candidate, then decrease pos by 2.
   e. Let candidate be the substring of candidate from position 0 to position pos-1.

10.2.2 LookupMatch (availableLocales, requestedLocales)

The LookupMatch abstract operation compares requestedLocales, which must be a LocaleList object representing a BCP 47 language priority list, against the locales in availableLocales and determines the best available language to meet the request. The following steps are taken:

1. Let i be 0.
2. Let len be the result of calling the [[Get]] internal method of requestedLocales with argument "length".
3. Let availableLocales be i.

NOTE Implementations should include in availableLocales locales that can serve as fallbacks in the algorithm used to resolve locales (see 10.2.4). For example, implementations shouldn't just provide a "de-DE" locale; they should include a "de" locale that can serve as a fallback for requests such as "de-AT" and "de-CH". For locales that in current usage would include a script subtag (such as Chinese locales), old-style language tags without script subtags should be included such that, for example, requests for "zh-TW" and "zh-HK" lead to output in traditional Chinese rather than the default simplified Chinese.
The following steps are taken:

4. Repeat while i < len and availableIndex ≠ -1:
   a. Let locale be the result of calling the [[Get]] internal method of availableLocales with argument
      ToString(i).
   b. Let noExtensionsLocale be the String value that is locale with all Unicode locale extension sequences
      removed.
   c. Let availableIndex be the result of calling the IndexOfMatch abstract operation with arguments
      availableLocales and noExtensionsLocale.
   d. Increase i by 1.

5. Let result be the result of creating a new object as if by the expression new Object() where Object is the
   standard built-in constructor with that name.

6. If availableIndex ≠ -1, then
   a. Let availableLocale be the result of calling the [[Get]] internal method of availableLocales with argument
      ToString(availableIndex).
   b. Set the [[locale]] internal property of result to availableLocale.
   c. If locale and noExtensionsLocale are not the same String value, then
      i. Let extension be the String value consisting of the first substring of locale that is a Unicode locale
         extension sequence.
      ii. Let extensionIndex be the character position of the initial “-” of the first Unicode locale extension
          sequence within locale.
      iii. Set the [[extension]] internal property of result to extension.
      iv. Set the [[extensionIndex]] internal property of result to extensionIndex.

7. Else
   a. Set the [[locale]] internal property of result to the value returned by the DefaultLocale abstract operation.

8. Return result.

NOTE: The algorithm is based on the Lookup algorithm described in RFC 4647 section 3.4, but options specified
through Unicode locale extension sequences are ignored in the lookup. Information about such subsequences is returned
separately. The abstract operation returns an object with a locale property, whose value is the language tag of
the selected locale, which must be an element of availableLocales. If the language tag of the request locale that led to
the selected locale contained a Unicode locale extension sequence, then the returned object also contains an extension
property whose value is the first Unicode locale extension sequence, and an extensionIndex property whose value is the
index of the first Unicode locale extension sequence within the request locale language tag.

10.2.3 BestFitMatch (availableLocales, requestedLocales)

The BestFitMatch abstract operation compares requestedLocales, which must be a LocaleList object
representing a BCP 47 language priority list, against the locales in availableLocales and determines the best
available language to meet the request. The algorithm is implementation dependent, but should produce
results that a typical user of the requested locales would perceive as at least as good as those produced by
the LookupMatch abstract operation. Options specified through Unicode locale extension sequences must
be ignored by the algorithm. Information about such subsequences is returned separately. The abstract operation
returns an object with a locale property, whose value is the language tag of the selected locale, which must be
an element of availableLocales. If the language tag of the request locale that led to the selected locale
contained a Unicode locale extension sequence, then the returned object also contains an extension property
whose value is the first Unicode locale extension sequence, and an extensionIndex property whose value is the
index of the first Unicode locale extension sequence within the request locale language tag.

10.2.4 ResolveLocale (availableLocales, requestedLocales, options, relevantExtensionKeys, localeData)

The ResolveLocale abstract operation compares a BCP 47 language priority list requestedLocales against the
locales in availableLocales and determines the best available language to meet the request. Two algorithms
are available to match the locales: the Lookup algorithm described in RFC 4647 section 3.4, and an
implementation dependent best-fit algorithm. Independent of the locale matching algorithm, options specified
through Unicode locale extension sequences are negotiated separately, taking the caller’s relevant extension
keys and locale data as well as client-provided options into consideration. The abstract operation returns an
object with a locale property whose value is the language tag of the selected locale, and properties for each
key in relevantExtensionKeys providing the selected value for that key.

The following steps are taken:
1. If `requestedLocales` is `undefined`, then
   a. Let `requestedLocales` be the result of creating a new `LocaleList` object as if by the expression `new Intl.LocaleList()` where `Intl.LocaleList` is the standard built-in constructor defined in 9.1.3.
2. Else
   a. Let `requestedLocales` be `ToObject(requestedLocales)`.
   b. If `requestedLocales` does not have an [[initializedName]], then
      i. Let `requestedLocales` be the result of creating a new `LocaleList` object as if by the expression `new Intl.LocaleList(requestedLocales)`, where `Intl.LocaleList` is the standard built-in constructor defined in 9.1.3.
3. Let `matcher` be the value of the `[[localeMatcher]]` internal property of `options`.
4. If `matcher` equals "lookup" then
   a. Let `r` be the result of calling the `lookupMatch` abstract operation with arguments `availableLocales` and `requestedLocales`.
5. Else
   a. Let `r` be the result of calling the `BestFitMatch` abstract operation with arguments `availableLocales` and `requestedLocales`.
6. Let `foundLocale` be the `value` of the `[[locales]]` internal property of `r`.
7. Let `extension` be the `value` of the `[[extension]]` internal property of `r`.
8. If `extension` is not `undefined`, then
   a. Let `extensionIndex` be the `value` of the `[[extensionIndex]]` internal property of `r`.
   b. Let `split` be the standard built-in function object defined in ES5, 15.5.4.14.
   c. Let `extensionSubtags` be the result of calling the `[[Call]]` internal method of `split` with `extension` as the this value and an argument list containing the single item `""`.
   d. Let `extensionSubtagsLength` be the result of calling the `[[Get]]` internal method of `extensionSubtags` with argument `"length"`.
9. Let `result` be the result of creating a new object as if by the expression `new Object()` where `Object` is the standard built-in constructor with that name.
10. Set the `[[availableLocales]]` internal property of `result` to `foundLocale`.
11. Let `supportedExtension` be `"-u"`.
12. Let `i` be `0`.
13. Let `len` be the result of calling the `[[Get]]` internal method of `relevantExtensionKeys` with argument `"length"`.
14. Repeat while `i < len`:
   a. Let `key` be the result of calling the `[[Get]]` internal method of `relevantExtensionKeys` with argument `ToString(i)`.
   b. Let `foundLocaleData` be the result of calling the `[[Get]]` internal method of `localeData` with the argument `foundLocale`.
   c. Let `keyLocaleData` be the result of calling the `[[Get]]` internal method of `foundLocaleData` with the argument `key`.
   d. Let `value` be the result of calling the `[[Get]]` internal method of `keyLocaleData` with argument `"0"`.
   e. Let `supportedExtensionAddition` be `""`.
   f. Let `indexOf` be the standard built-in function object defined in ES5, 15.4.4.14.
   g. If `extensionSubtags` is `undefined`, then
      i. Let `keyPos` be the result of calling the `[[Call]]` internal method of `indexOf` with `extensionSubtags` as the this value and an argument list containing the single item `key`.
      ii. If `keyPos < 0` then
          1. If `keyPos + 1 < extensionSubtagsLength` and the length of the result of calling the `[[Get]]` internal method of `extensionSubtags` with argument `ToString(keyPos + 1)` is greater than `0`, then
              a. Let `requestedValue` be the result of calling the `[[Get]]` internal method of `extensionSubtags` with argument `ToString(keyPos + 1)`.
              b. Let `valuePos` be the result of calling the `[[Call]]` internal method of `indexOf` with `keyLocaleData` as the this value and an argument list containing the single item `requestedValue`.
              c. If `valuePos < 0` then
                  i. Let `value` be `requestedValue`.
                  ii. Let `supportedExtensionAddition` be the concatenation of `"-u", key, "-u", and value`.
1. End while...
Let valuePos be the result of calling the [[Call]] internal method of indexOf with keyLocaleData as the this value and an argument list containing the single item "true".

a. If valuePos = -1, then let value be "true".
b. Otherwise, let optionsValue be the value of the [[Get]] internal method of options with key "optionsValue".
   i. If optionsValue is not undefined and the result of calling the [[Call]] internal method of indexOf with keyLocaleData as the this value and an argument list containing the single item optionsValue is not -1, then
      1. Let value be optionsValue.
      2. Let supportedExtensionAddition be "".
   j. Set the [[Get]] internal property of result to value.
   k. Append supportedExtensionAddition to supportedExtension.
   l. Increase i by 1.

15. If the length of supportedExtension is greater than 2, then
   a. Let preExtension be the substring of foundLocale from position 0 to position extensionIndex - 1.
   b. Let postExtension be the substring of foundLocale from position extensionIndex to the end of the string.
   c. Let foundLocale be the concatenation of preExtension, supportedExtension, and postExtension.

16. The following steps are taken:

10.2.5 LookupSupportedLocales (availableLocales, requestedLocales)

The LookupSupportedLocales abstract operation returns the subset of the provided BCP 47 language priority list requestedLocales for which availableLocales has a matching locale when using the BCP 47 Lookup algorithm. Locales appear in the same order in the returned list as in requestedLocales. The following steps are taken:

1. Let len be the result of calling the [[Get]] internal method of requestedLocales with the argument "length".
2. Let subset be a new empty List.
3. Let k be 0.
4. Repeat while k < len
   a. Let locale be the result of calling the [[Get]] internal method of requestedLocales with argument ToString(locale).
   b. Let noExtensionsLocale be the string value that is locale with all Unicode locale extension sequences removed.
   c. Let availableIndex be the result of calling the IndexOfMatch abstract operation with arguments availableLocales and noExtensionsLocale.
   d. If availableIndex ≠ -1, then append locale to the end of subset.
   e. Increment k by 1.
5. Let subsetArray be an Array object whose elements are the same values in the same order as the elements of subset.
6. Return a new LocaleList object created as if by the expression new Intl.LocaleList(subsetArray), where Intl.LocaleList is the standard built-in constructor defined in 9.1.3.

10.2.6 BestFitSupportedLocales (availableLocales, requestedLocales)

The BestFitSupportedLocales abstract operation returns the subset of the provided BCP 47 language priority list requestedLocales for which availableLocales has a matching locale when using the Best Fit Match algorithm. Locales appear in the same order in the returned list as in requestedLocales. The steps taken are implementation dependent.

10.2.7 SupportedLocales (availableLocales, requestedLocales, options)

The SupportedLocales abstract operation returns the subset of the provided BCP 47 language priority list requestedLocales for which availableLocales has a matching locale. Two algorithms are available to match the locales: the Lookup algorithm described in RFC 4647 section 3.4, and an implementation dependent best-fit algorithm. Locales appear in the same order in the returned list as in requestedLocales. The following steps are taken:

1. Let requestedLocales be ToObject(requestedLocales).
2. If requestedLocales does not have an [[InitializedLocaleList]] internal property with value true, then
   a. Let requestedLocales be a new LocaleList object created as if by the expression `new Intl.LocaleList(requestedLocales)`, where Intl/localeList is the standard built-in constructor defined in 9.1.3.

1. If options is not undefined, then
   a. Let matcher be the result of calling the [[Get]] internal method of options with argument "localeMatcher".
      b. If matcher is not undefined, then
         i. Let matcher be ToString(matcher).
         ii. If matcher is not equal to "lookup" or "best fit", then throw a RangeError exception.
   4. If matcher is undefined or equals "best fit" then
      a. Return the result of calling the BestFitSupportedLocales abstract operation with arguments availableLocales and requestedLocales.
   5. Else
      a. Return the result of calling the LookupSupportedLocales abstract operation with arguments availableLocales and requestedLocales.

10.2.8 GetGetOption (options)

The GetGetOption abstract operation returns a function that extracts a property value from the provided options object, converts it to the required type, checks whether it is one of a list of allowed values, and fills in a fallback value if necessary.

When the GetGetOption abstract operation is called with argument options, the following steps are taken.

1. Let getOption be a function which, when called with arguments property, type, values, and fallback, takes the following steps:
   a. Let value be the result of calling the [[Get]] internal method of options with argument property.
      b. If value is neither undefined nor null then
         i. If type equals "boolean" then let value be ToBoolean(value).
         ii. If type equals "string" then let value be ToString(value).
         iii. If type equals "number" then let value be ToNumber(value).
         iv. If values is not undefined, then
            i. If the result of calling the indexOf method of values with argument value is -1, then throw a RangeError exception.
            v. Return value.
      c. Else return fallback.
   2. Return getOption.

10.2.9 GetGetNumberOption (options)

The GetGetNumberOption abstract operation returns a function that extracts a property value from the provided options object, converts it to a Number value, checks whether it is in the allowed range, and fills in a fallback value if necessary.

When the GetGetNumberOption abstract operation is called with argument options, the following steps are taken.

1. Let getNumberOption be a function which, when called with arguments property, minimum, maximum, and fallback, takes the following steps:
   a. Let value be the result of calling the [[Get]] internal method of options with argument property.
      b. If value is neither undefined nor null then
         i. If value is NaN or less than minimum or greater than maximum, throw a RangeError exception.
         iii. Return max(value).
      c. Else return fallback.
   2. Return getNumberOption.
11 Collator Objects

TheCollator constructor is a property of theIntl object. Behavior common to all service constructor properties of theIntl object is specified in10.1.

11.1 TheCollator Constructor

11.1.1 Initializing an Object as a Collator

The abstract operation InitializeCollator accepts the argumentcollator, which must be an object, and theoptional argumentslocaleList andoptions. It initializescollator as aCollator object. The computation uses theabstract operations ResolveLocale (10.2.4) and GetGetOption (10.2.8).

Several steps in the algorithm use values from the following table, which associates Unicode locale extension keys, property names, types, and allowable values:

<table>
<thead>
<tr>
<th>Key</th>
<th>Property</th>
<th>Type</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>kb</td>
<td>backwards</td>
<td>&quot;boolean&quot;</td>
<td></td>
</tr>
<tr>
<td>kc</td>
<td>caseLevel</td>
<td>&quot;boolean&quot;</td>
<td></td>
</tr>
<tr>
<td>kn</td>
<td>numeric</td>
<td>&quot;boolean&quot;</td>
<td></td>
</tr>
<tr>
<td>kh</td>
<td>hiraganaQuaternary</td>
<td>&quot;boolean&quot;</td>
<td></td>
</tr>
<tr>
<td>kk</td>
<td>normalization</td>
<td>&quot;boolean&quot;</td>
<td></td>
</tr>
<tr>
<td>kf</td>
<td>caseFirst</td>
<td>&quot;string&quot;</td>
<td>&quot;upper&quot;, &quot;lower&quot;, &quot;false&quot;</td>
</tr>
</tbody>
</table>

The following steps are taken:

1. Ifoptions is not provided or isundefined, then
   a. Letoptions be the result of creating a new object as if by the expressionnewObject()whereObjectis the standard built-in constructor with that name.
2. Else
   a. Letoptions be ToObject(options).
3. LetgetOption be the result of calling the GetGetOption abstract operation with argumentoptions.
4. Letube the result of calling getOption with arguments"usage","string","["sort", "search"]", and"sort".
5. Set the[[usage]] internal property ofcollator tou.
6. Ifu is equal to"sort", then letlocaleData be the value of the [[sortLocaleData]] internal property ofIntl Collator; else letlocaleData be the value of the [[searchLocaleData]] internal property ofIntl Collator.
7. Letopt be the result of creating a new object as if by the expressionnewObject()whereObjectis the standard built-in constructor with that name.
8. Letmatcher be the result of calling getOption with the arguments"localeMatcher","string","["lookup","best fit"], and"best fit".
9. Set the[[localeMatcher]] internal property ofopt tomatcher.
10. For each row in Table 1, except the header row, do:
    a. Letkey be the name given in the Key column of the row.
    b. Letvalue be the result of calling getOption, passing as arguments the name given in the Property column of the row, the string given in the Type column of the row, and, if the Values column of the row contains strings, an array containing those strings.
    c. Ifthestring given in the Type column of the row is"boolean" and value is notundefined, then
       i. Letvalue beToString(value).
    d. Setthe[[keys]] internal property ofopt tovalue.
11. LetrelevantExtensionKeys be the value of the [[relevantExtensionKeys]] internal property ofIntl Collator.
12. Letr be the result of calling the ResolveLocale abstract operation with the [[availableLocales]] internal property ofIntl Collator, thelocaleList argument, opt, relevantExtensionKeys, andlocaleData.
13. Set the [[locale]] internal property ofcollator to the value of the [[locale]] internal property ofr.
14. Let \( i \) be 0.
15. Let \( \text{len} \) be the result of calling the \([\text{Get}]\) internal method of `relevantExtensions` with argument `"length"`.
16. Repeat while \( i < \text{len} \):
   a. Let key be the result of calling the \([\text{Get}]\) internal method of `relevantExtensions` with argument `"\text{ToString}(i)"`.
   b. If key is equal to `"co"`, then
      i. Let property be `"collation"`
      ii. Let value be the value of the \([\text{call}]\) internal property of \( r \).
   c. Else use the row of Table 1 that contains the value of key in the Key column:
      i. Let property be the name given in the Property column of the row.
      ii. Let value be the value of the \([\text{Get}]\) internal property of \( r \).
      iii. If the name given in the Type column of the row is `"boolean"`, then let value be the result of comparing value with `"true"`.
   d. Set the \([\text{Get}]\) internal property of `collator` to value.
   e. Increase \( i \) by 1.
17. Let \( s \) be the result of calling `getOption` with arguments `"sensitivity"`, `"string"`, and `"["base", "accent", "case", "variant"]"`.
18. If \( s \) is undefined, then
   a. If \( s \) is equal to `"sort"`, then let \( s \) be `"variant"`.
   b. Else
      i. Let `dataLocale` be the value of the \([\text{GetProperty}]\) internal property of \( r \).
      ii. Let `dataLocaleData` be the result of calling the \([\text{Get}]\) internal operation of `localeData` with argument `dataLocale`.
      iii. Let \( s \) be the result of calling the \([\text{Get}]\) internal operation of `dataLocaleData` with argument `"sensitivity"`.
19. Set the \([\text{GetProperty}]\) internal property of `collator` to \( s \).
20. Let \( p \) be the result of calling `getOption` with arguments `"ignorePunctuation"`, `"boolean"`, undefined, and false.
21. Set the \([\text{GetProperty}]\) internal property of `collator` to \( p \).
22. Set the \([\text{GetProperty}]\) internal property of `collator` to undefined.
23. Set the \([\text{GetProperty}]\) internal property of `collator` to true.

11.1.2 The Intl.Collator Constructor Called as a Function

When Intl.Collator is called as a function rather than as a constructor, it accepts the optional arguments `localeList` and `options` and takes the following steps:

1. If this is the Intl object or `undefined`, then
   a. Return the result of creating a new object as if by the expression `new Intl.Collator(localeList, options)`, where Intl.Collator is the standard built-in constructor defined in 11.1.3.
2. Let \( \text{obj} \) be the result of calling `ToObject` passing the this value as the argument.
3. Call the `InitializeCollator` abstract operation with arguments \( \text{obj}, \text{localeList}, \) and `options`.
4. Return `\text{obj}`.

11.1.3 The Intl.Collator Constructor Used in a new Expression

When Intl.Collator is called as part of a new expression, it is a constructor. It accepts the optional arguments `localeList` and `options`, and initializes the properties of the newly constructed object by calling the `InitializeCollator` abstract operation [11.1.1], passing the newly constructed object, `localeList`, and `options` as arguments.

The \([\text{Prototype}]\) internal property of the newly constructed object is set to the original Intl.Collator prototype object, the one that is the value of Intl.Collator.prototype (11.2.1).

The \([\text{Extensible}]\) internal property of the newly constructed object is set to true.

© Ecma International 2012
11.2 Properties of the \texttt{Intl.Collator} Constructor

Besides the internal properties and the length property (whose value is 2), the \texttt{Intl.Collator} constructor has the following properties:

11.2.1 \texttt{Intl.Collator.prototype}

The value of \texttt{Intl.Collator.prototype} is the built-in \texttt{Intl} Collator prototype object (11.3).

This property has the attributes \{ [[\texttt{Writable}]]: false, [[\texttt{Enumerable}]]: false, [[\texttt{Configurable}]]: false \}.

11.2.2 \texttt{Intl.Collator.supportedLocalesOf (requestedLocales [, options])}

When the \texttt{supportedLocalesOf} method of \texttt{Intl.Collator} is called, the following steps are taken:

1. Let \texttt{availableLocales} be the value of the [[\texttt{availableLocales}]] internal property of \texttt{Intl.Collator}.
2. Return the result of calling the \texttt{SupportedLocales} abstract operation with arguments \texttt{availableLocales}, \texttt{requestedLocales}, and \texttt{options}.

11.2.3 Internal Properties

The value of the [[\texttt{availableLocales}]] internal property is implementation dependent within the constraints described in 10.1.

The value of the [[\texttt{relevantExtensionKeys}]] internal property is an array that must include the element "co", may include any or all of the elements "kb", "kc", "kn", "kh", "kk", "kf", and must not include any other elements.

\textbf{NOTE} Unicode Technical Standard 35 describes ten locale extension keys that are relevant to collation: "co" for collator usage and specializations, "ka" for alternate handling, "kb" for backward second level weight, "kc" for case level, "kn" for numeric, "kh" for hiragana quaternary, "kk" for normalization, "kf" for case first, "ks" for collation strength, and "vt" for variable top. Collator, however, requires that the usage is specified through the usage property of the options object, alternate handling through the ignorePunctuation property of the options object, and the strength through the sensitivity property of the options object. The "co" key in the language tag is supported only for collator specializations, and the key "vt" is not supported in this version of the Internationalization API. Support for the remaining keys is implementation dependent.

The values of the [[\texttt{sortLocaleData}]] and [[\texttt{searchLocaleData}]] internal properties are implementation dependent within the constraints described in 10.1 and the following additional constraints:

- The first element of [[\texttt{sortLocaleData}]]\texttt{locale}.co and [[\texttt{searchLocaleData}]]\texttt{locale}.co must be null for all locale values.
- The values "standard" and "search" must not be used as elements in any [[\texttt{sortLocaleData}]]\texttt{locale}.co and [[\texttt{searchLocaleData}]]\texttt{locale}.co array.
- [[\texttt{searchLocaleData}]]\texttt{locale} must have a sensitivity property with a String value equal to "base", "accent", "case", or "variant" for all locale values.

11.3 Properties of the \texttt{Intl.Collator} Prototype Object

The \texttt{Intl.Collator} prototype object is itself an \texttt{Intl.Collator} instance as specified in 11.4, whose internal properties are set as if it had been constructed by the expression \texttt{new Intl.Collator()}. In the following descriptions of functions that are properties of the \texttt{Intl.Collator} prototype object, the phrase "this Collator object" refers to the object that is the this value for the invocation of the function.

11.3.1 \texttt{Intl.Collator.prototype.constructor}

The initial value of \texttt{Intl.Collator.prototype.constructor} is the built-in \texttt{Intl.Collator} constructor.
11.3.2 Compare (collator, x, y)

When the `Compare` abstract operation is called with arguments `collator` (which must be a Collator object), `x` and `y`, it returns a Number other than NaN that represents the result of a locale-sensitive String comparison of `x` (converted to a String) with `y` (converted to a String). The two Strings are `x` and `y`. The two Strings are compared in an implementation-defined fashion. The result is intended to order String values in the sort order specified by the effective locale and collation options computed during construction of `collator`, and will be negative, zero, or positive, depending on whether `x` comes before `y` in the sort order, the Strings are equal under the sort order, or `x` comes after `y` in the sort order, respectively.

The sensitivity of `collator` is interpreted as follows:

- base: Only strings that differ in base letters compare as unequal. Examples: `a ≠ b`, `a = á`, `a ≠ A`, `b = ß`.
- accent: Only strings that differ in base letters or accents compare as unequal. Examples: `a ≠ b`, `a ≠ á`, `a = A`, `b = ß`.
- case: Only strings that differ in base letters or case compare as unequal. Examples: `a ≠ b`, `a = á`, `a ≠ A`, `b = ß`.
- variant: Strings that differ in base letters, accents, case, or width compare as unequal. Examples: `a ≠ b`, `a ≠ á`, `a ≠ A`, `b ≠ ß`.

If the collator is set to ignore punctuation, then strings that differ only in punctuation do not compare as unequal. Applications should not assume that the `toString` method of `collator` will return a `string`.

The actual return values are implementation-defined to permit implementers to encode additional information in the value, but the method is required to define a total ordering on all Strings and to return 0 when comparing Strings that are considered canonically equal by the Unicode standard.

NOTE 1 It is recommended that the `Compare` abstract operation be implemented following Unicode Technical Standard 10, `Unicode Collation Algorithm`, using tailorings for the effective locale and collation options of `collator`.

NOTE 2 Applications should not assume that the behavior of the `Compare` abstract operation for Collator instances with the same resolved options will remain the same for different versions of the same implementation.

11.3.3 Intl.Collator.prototype.compare

This named accessor property returns a function that compares two strings according to the sort order of this Collator. The function is bound to this Collator, so that it can be passed directly to Array.prototype.sort.

The value of the `[[Get]]` attribute is a function that takes the following steps:

1. If this Collator does not have an `[[initializedCollator]]` internal property with value `true`, then throw a `TypeError` exception.
2. If the `[[boundCompare]]` internal property of this Collator is `undefined`, then:
   a. Let `th` be this.
   b. Let `bc` be a function that takes the arguments `x` and `y` and performs the following steps:
      i. Return the result of calling the `Compare` abstract operation with arguments `th`, `x`, and `y`.
   c. Set the `[[boundCompare]]` internal property of this Collator to `bc`.
3. Return the value of the `[[boundCompare]]` internal property of this Collator.
The [[Set]] attribute is undefined.

### 11.3.4 Intl.Collator.prototype.resolvedOptions

This named accessor property provides access to the locale and collation options computed during initialization of the object.

The value of the [[Get]] attribute is a function that returns a new object with properties locale, usage, sensitivity, ignorePunctuation, collation, as well as those properties shown in Table 1 whose keys are included in the [[relevantExtensionKeys]] internal property of Intl.Collator. Each property has the value of the corresponding internal property of this Collator object (see 11.4). If the accessor is called on an object that does not have an [[initializedCollator]] internal property with value true, then a TypeError is thrown.

The [[Set]] attribute is undefined.

### 11.4 Properties of Intl.Collator Instances

Intl.Collator instances and other objects that have been successfully initialized as a Collator have an [[initializedCollator]] internal property whose value is true.

Objects that have been successfully initialized as a Collator also have several internal properties that are computed by the constructor:

- [[locale]] is a String value with the language tag of the locale whose localization is used for collation.
- [[usage]] is one of the String values "sort" or "search", identifying the collator usage.
- [[sensitivity]] is one of the String values "base", "accent", "case", or "variant", identifying the collator's sensitivity.
- [[ignorePunctuation]] is a Boolean value, specifying whether punctuation should be ignored in comparisons.
- [[collation]] is a String value with the "type" given in Unicode Technical Standard 35 for the collation, except that the values "standard" and "search" are not allowed, while the value "default" is allowed.

Objects that have been successfully initialized as a Collator also have the following internal properties if the key corresponding to the name of the internal property in Table 1 is included in the [[relevantExtensionKeys]] internal property of Intl.Collator:

- [[backwards]] is a Boolean value, specifying whether backward second level weight is used.
- [[caseLevel]] is a Boolean value, specifying whether case level adjustment is used.
- [[numeric]] is a Boolean value, specifying whether numeric sorting is used.
- [[hiraganaQuaternary]] is a Boolean value, specifying whether hiragana characters receive special treatment at quaternary level.
- [[normalization]] is a Boolean value, specifying whether strings should be normalized before comparison.
- [[caseFirst]] is a String value; allowed values are specified in Table 1.

Finally, objects that have been successfully initialized as a Collator have a [[boundCompare]] internal property that caches the function returned by the compare method (11.3.3).

### 12 NumberFormat Objects

The NumberFormat constructor is a property of the Intl object. Behavior common to all service constructor properties of the Intl object is specified in 10.1.
12.1 The <code>Intl.NumberFormat</code> Constructor

### 12.1.1 Initializing an Object as a <code>NumberFormat</code>

The abstract operation <code>InitializeNumberFormat</code> accepts the argument <code>numberFormat</code>, which must be an object, and the optional arguments <code>localeList</code> and <code>options</code>. It initializes <code>numberFormat</code> as a <code>NumberFormat</code> object. The computation uses the abstract operations <code>ResolveLocale</code> (10.2.4), <code>GetOption</code> (10.2.8), <code>GetGetNumberOption</code> (10.2.9), and <code>CurrencyDigits</code> (defined below).

The following steps are taken:

1. If <code>options</code> is not provided or is <code>undefined</code>, then
   a. Let <code>options</code> be the result of creating a new object as if by the expression `new Object()` where <code>Object</code> is the standard built-in constructor with that name.
2. Else
   a. Let options be ToObject(options).
3. Let <code>getOption</code> be the result of calling the <code>GetGetOption</code> abstract operation with argument options.
4. Let <code>getNumberOption</code> be the result of calling the <code>GetGetNumberOption</code> abstract operation with argument options.
5. Let <code>opt</code> be the result of creating a new object as if by the expression `new Object()` where <code>Object</code> is the standard built-in constructor with that name.
6. Let <code>matcher</code> be the result of calling <code>getOption</code> with the arguments "localeMatcher", "string", ["lookup", "best fit"], and "best fit".
7. Set the [localeMatcher] internal property of opt to matcher.
8. Let <code>localeData</code> be the value of the [localeData] internal property of <code>Intl.NumberFormat</code>.
9. Let <code>r</code> be the result of calling the <code>ResolveLocale</code> abstract operation with the [availableLocales] internal property of <code>Intl.NumberFormat</code>, the <code>localeList</code> argument, opt, the [relevantExtensionKeys] internal property of <code>Intl.NumberFormat</code>, and <code>localeData</code>.
10. Set the [locale] internal property of <code>numberFormat</code> to the value of the [locale] internal property of <code>r</code>.
11. Set the [numberingSystem] internal property of <code>numberFormat</code> to the value of the [nu] internal property of <code>r</code>.
12. Let <code>dataLocale</code> be the value of the [dataLocale] internal property of <code>r</code>.
13. Let <code>s</code> be the result of calling <code>getOption</code> with the arguments "style", "string", ["decimal", "percent", "currency"], and "decimal".
14. Set the [style] internal property of <code>numberFormat</code> to <code>s</code>.
15. Let <code>c</code> be the result of calling <code>getOption</code> with the arguments "currency" and "string".
16. If <code>c</code> is not undefined and the result of calling the <code>IsWellFormedCurrencyCode</code> abstract operation with argument <code>c</code> is false, then throw a <code>RangeError</code> exception.
17. If <code>c</code> is equal to "currency" and <code>c</code> is undefined, throw a <code>TypeError</code> exception.
18. If <code>s</code> is equal to "currency", then
   a. Let <code>c</code> be the result of converting <code>c</code> to uppercase as specified in 6.1.
   b. Set the [currency] internal property of <code>numberFormat</code> to <code>c</code>.
19. Let <code>cd</code> be the result of calling <code>getOption</code> with the arguments "currencyDisplay", "string", ["code", "symbol", "name"], and "symbol".
20. If <code>c</code> is equal to "currency" then set the [currencyDisplay] internal property of <code>numberFormat</code> to <code>cd</code>.
21. Let <code>cd</code> be the result of calling <code>getOption</code> with the arguments "minimumIntegerDigits", 1, 21, and 1.
22. Set the [minimumIntegerDigits] internal property of <code>numberFormat</code> to <code>cd</code>.
23. If <code>s</code> is equal to "currency" then let <code>mxfd</code> be <code>CurrencyDigits(c)</code>; else let <code>mxfd</code> be undefined.
24. Let <code>mxfd</code> be the result of calling <code>getOption</code> with the arguments "minimumFractionDigits", 0, 20, and <code>mxfd</code>.
25. Set the [minimumFractionDigits] internal property of <code>numberFormat</code> to <code>mxfd</code>.
26. If <code>s</code> is equal to "currency" then let <code>mnsd</code> be <code>CurrencyDigits(c)</code>; else if <code>s</code> is equal to "percent" then let <code>mnsd</code> be max(<code>mnsd</code>, 0); else let <code>mnsd</code> be max(<code>mnsd</code>, 3).
27. Let <code>mnsd</code> be the result of calling <code>getOption</code> with the arguments "maximumFractionDigits", <code>mnsd</code>, 20, and <code>mnsd</code>.
28. Set the [maximumFractionDigits] internal property of <code>numberFormat</code> to <code>mnsd</code>.
29. If <code>s</code> is equal to "currency" then let <code>mnfd</code> be <code>CurrencyDigits(c)</code>; else if <code>s</code> is equal to "percent" then let <code>mnfd</code> be max(<code>mnfd</code>, 0); else let <code>mnfd</code> be max(<code>mnfd</code>, 3).
30. Let <code>mnfd</code> be the result of calling <code>getOption</code> with the arguments "maximumSignificantDigits", <code>mnfd</code>, 20, and <code>mnfd</code>.
31. Set the [maximumSignificantDigits] internal property of <code>numberFormat</code> to <code>mnfd</code>.
32. If <code>s</code> is equal to "currency" then let <code>opt</code> be the result of calling <code>getOption</code> with the arguments "minimumSignificantDigits", 1, 21, and 1.
33. Let <code>opt</code> be the result of calling <code>getOption</code> with the arguments "minimumSignificantDigits", 1, 21, and 1.
12.2.1 The Intl.NumberFormat Constructor Called as a Function

When Intl.NumberFormat is called as a function rather than as a constructor, it accepts the optional arguments localeList and options and takes the following steps:

1. If this is the Intl object or undefined, then
   a. Return the result of creating a new object as if by the expression new Intl.NumberFormat(localeList, options), where Intl.NumberFormat is the standard built-in constructor defined in 12.1.3.
2. Let obj be the result of calling ToObject passing the this value as the argument.
3. Call the InitializeNumberFormat abstract operation with arguments obj, localeList, and options.
4. Return obj.

12.1.3 The Intl.NumberFormat Constructor Used in a new Expression

When Intl.NumberFormat is called as part of a new expression, it is a constructor. It accepts the optional arguments localeList and options, and initializes the properties of the newly constructed object by calling the InitializeNumberFormat abstract operation (12.1.1), passing the newly constructed object, localeList, and options as arguments.

The [[Prototype]] internal property of the newly constructed object is set to the original Intl.NumberFormat prototype object, the one that is the value of Intl.NumberFormat.prototype (12.2.1).

The [[Extensible]] internal property of the newly constructed object is set to true.

12.2 Properties of the Intl.NumberFormat Constructor

Besides the internal properties and the length property (whose value is 2), the Intl.NumberFormat constructor has the following properties:

12.2.1 Intl.NumberFormat.prototype

The value of Intl.NumberFormat.prototype is the built-in Intl.NumberFormat prototype object (12.3).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }. 

b. Let mxsd be the result of calling getNumberOption with the arguments "maximumSignificantDigits", mxsd, 21, and 21.
c. Set the [[maximumSignificantDigits]] internal property of numberFormat to mxsd, and the [[negativePattern]] internal property of numberFormat to g.

31. Let g be the result of calling getOption with the arguments “useGrouping”, “boolean”, undefined, and true.
32. Set the [[useGrouping]] internal property of numberFormat to g.
33. Let dataLocaleData be the result of calling the [[Get]] internal method of localeData with argument dataLocale.
34. Let patterns be the result of calling the [[Get]] internal method of dataLocaleData with argument "patterns".
35. Let patterns be the result of calling the [[Get]] internal method of patterns with argument s.
36. Set the [[positivePattern]] internal property of numberFormat to the result of calling the [[Get]] internal method of patterns with the argument "positivePattern".
37. Set the [[negativePattern]] internal property of numberFormat to the result of calling the [[Get]] internal method of patterns with the argument "negativePattern".
38. Set the [[initializedNumberFormat]] internal property of numberFormat to true.

When the CurrencyDigits abstract operation is called with an argument currency (which must be an upper case String value), the following steps are taken:

1. If the ISO 4217 currency and funds code list contains currency as an alphabetic code, then return the minor unit value corresponding to the currency from the list; else return 2.

© Ecma International 2012
12.2.2 Intl.NumberFormat.supportedLocalesOf (requestedLocales [, options])

When the supportedLocalesOf method of Intl.NumberFormat is called, the following steps are taken:

1. Let availableLocales be the value of the [[availableLocales]] internal property of Intl.NumberFormat.
2. Return the result of calling the supportedLocales abstract operation with arguments availableLocales, requestedLocales, and options.

12.2.3 Internal Properties

The value of the [[availableLocales]] internal property is implementation dependent within the constraints described in 10.1.

The value of the [[relevantExtensionKeys]] internal property is "nu".

**NOTE** Unicode Technical Standard 35 describes two locale extension keys that are relevant to number formatting, "nu" for numbering system and "cu" for currency. Intl.NumberFormat, however, requires that the currency of a currency format is specified through the currency property in the options objects.

The value of the [[localeData]] internal property is implementation dependent within the constraints described in 10.1 and the following additional constraints:

- [[localeData][locale]] must have a patterns property for all locale values. The value of this property must contain a substring "(number)": the values within the currency property must also contain a substring "(currency)". The pattern strings must not contain digits as specified by the Unicode Standard.

12.3 Properties of the Intl.NumberFormat Prototype Object

The Intl.NumberFormat prototype object is itself an Intl.NumberFormat instance as specified in 12.4, whose internal properties are set as if it had been constructed by the expression new Intl.NumberFormat().

In the following descriptions of functions that are properties of the Intl.NumberFormat prototype object, the phrase "this NumberFormat object" refers to the object that is the this value for the invocation of the function.

12.3.1 Intl.NumberFormat.prototype.constructor

The initial value of Intl.NumberFormat.prototype.constructor is the built-in Intl.NumberFormat constructor.

12.3.2 Intl.NumberFormat.prototype.format (value)

Returns a String value representing the result of calling ToNumber(value) according to the effective locale and the formatting options of this NumberFormat object. The computation uses the abstract operations ToRawPrecision and ToRawFixed (defined below).

The computations rely on String values and locations within numeric strings that are implementation and locale dependent ("ILD") or implementation, locale, and numbering system dependent ("ILND"). The ILD and ILND Strings mentioned must not contain digits as specified by the Unicode Standard.

The following steps are taken:

1. If this NumberFormat object does not have an [[initializedNumberFormat]] internal property with value true, then throw a TypeError exception.
2. Let x be ToNumber(value).
3. Let negative be false.
4. If the result of isFinite(x) is false, then

© Ecma International 2012
a. If \( \times \) is \( \text{NaN} \), then let \( n \) be an ILD String value indicating the \( \text{NaN} \) value.
   Else
   i. Let \( n \) be an ILD String value indicating infinity.
      ii. If \( x < 0 \), then let negative be true.
5. Else
   a. If \( x < 0 \), then
      i. Let negative be true.
      ii. Let \( x \) be -x.
   b. If the value of the \([\text{style}]\) internal property of this NumberFormat object is "percent", let \( x \) be \( 100 \times x \).
   c. If the \([\text{minimumSignificantDigits}]\) and \([\text{maximumSignificantDigits}]\) internal properties of this NumberFormat object are present, then
      i. Let \( n \) be the result of calling ToRawPrecision, passing as arguments \( x \) and the values of the \([\text{minimumSignificantDigits}]\) and \([\text{maximumSignificantDigits}]\) internal properties of this NumberFormat object.
   d. Else
      i. Let \( n \) be the result of calling ToRawFixed, passing as arguments \( x \) and the values of the \([\text{minimumIntegerDigits}]\), \([\text{minimumFractionDigits}]\), \([\text{maximumSignificantDigits}]\), \([\text{minimumSignificantDigits}]\), \([\text{maximumFractionDigits}]\) internal properties of this NumberFormat object.
   e. If the value of the \([\text{numberingSystem}]\) internal property of this NumberFormat object matches one of the values in the "Numbering System" column of Table 2 below, then
      i. Let digits be a String value containing exactly the 10 digits specified in the "Digits" column of Table 2 in the row containing the value of the \([\text{numberingSystem}]\) internal property.
      ii. Replace each digit in \( n \) with the value of digits[digit].
   f. Else use an implementation dependent algorithm to map \( n \) to the appropriate representation of \( n \) in the given numbering system.
   g. If \( n \) contains the character ",", then replace it with an ILND String representing the decimal separator.
   h. If the value of the \([\text{useGrouping}]\) internal property of this NumberFormat object is true, then insert an ILND String representing a grouping separator into an ILND set of locations within the integer part of \( n \).
6. If negative is true, then let result be the value of the \([\text{negativePattern}]\) internal property of this NumberFormat object; else let result be the value of the \([\text{positivePattern}]\) internal property of this NumberFormat object.
7. Replace the substring "\([\text{number}]\)" within result with \( n \).
8. If the value of the \([\text{style}]\) internal property of this NumberFormat object is "currency", then
   a. Let currency be the value of the \([\text{currency}]\) internal property of this NumberFormat object.
   b. If the value of the \([\text{currencyDisplay}]\) internal property of this NumberFormat object is "code", then let \( cd \) be currency.
   c. Else if the value of the \([\text{currencyDisplay}]\) internal property of this NumberFormat object is "symbol", then let \( cd \) be an ILD string representing currency in short form. If the implementation does not have such a representation of currency, then use currency itself.
   d. Else if the value of the \([\text{currencyDisplay}]\) internal property of this NumberFormat object is "name", then let \( cd \) be an ILD string representing currency in long form. If the implementation does not have such a representation of currency, then use currency itself.
   e. Replace the substring "\([\text{currency}]\)" within result with \( cd \).
9. Return result.

When the ToRawPrecision abstract operation is called with arguments \( x \) (which must be a finite non-negative number), minPrecision, and maxPrecision (both must be integers between 1 and 21) the following steps are taken:
1. Let \( p \) be maxPrecision.
2. If \( x = 0 \), then
   a. Let \( m \) be the String consisting of \( p \) occurrences of the character "0".
      b. Let \( e \) be 0.
3. Else
   a. Let \( e \) and \( n \) be integers such that \( 10^{p-1} \leq n < 10^p \) and for which the exact mathematical value of \( n \times 10^{-p+1} - x \) is as close to zero as possible. If there are two such sets of \( e \) and \( n \), pick the \( e \) and \( n \) for which \( n \times 10^{-p+1} \) is larger.
   b. Let \( m \) be the String consisting of the digits of the decimal representation of \( n \) (in order, with no leading zeroes).
4. If \( e \geq p \) then

© Ecma International 2012 21
a. Return the concatenation of \( m \) and \( e+p+1 \) occurrences of the character "0".
5. If \( e = p-1 \) then
   a. Return \( m \).
6. If \( e \geq 0 \) then
   a. Let \( m \) be the concatenation of the first \( e+1 \) characters of \( m \), the character ".", and the remaining \( p-(e+1) \) characters of \( m \).
7. If \( e < 0 \) then
   a. Let \( m \) be the concatenation of the String "0", ".", \( -(e+1) \) occurrences of the character "0", and the string \( m \).
8. Let \( period \) be the result of calling the indexOf method of \( m \) with argument ".".
9. If \( period > 0 \) and \( maxPrecision > minPrecision \) then
   a. Let \( cut \) be \( maxPrecision - minPrecision \).
      b. Repeat while \( cut > 0 \) and the last character of \( m \) is "0":
         i. Remove the last character from \( m \).
         ii. Decrease \( cut \) by 1.
      c. If the last character of \( m \) is ",", then
         i. Remove the last character from \( m \).
10. Return \( m \).

When the ToRawFixed abstract operation is called with arguments \( x \) (which must be a finite non-negative number), \( nInteger \) (which must be an integer between 1 and 21), \( minFraction \), and \( maxFraction \) (which must be integers between 0 and 20) the following steps are taken:

1. Let \( f \) be \( maxFraction \).
2. Let \( n \) be the number for which the exact mathematical value of \( n \times 10^\left(f-1\right) - x \) is as close to zero as possible. If there are two such \( n \), pick the larger \( n \).
3. If \( n = 0 \), let \( m \) be the String "0". Otherwise, let \( m \) be the String consisting of the digits of the decimal representation of \( n \) (in order, with no leading zeroes).
4. If \( f \neq 0 \), then
   a. Let \( k \) be the number of characters in \( m \).
      b. If \( k \leq f \), then
         i. Let \( z \) be the String consisting of \( f+1-k \) occurrences of the character "0".
         ii. Let \( m \) be the concatenation of Strings \( z \) and \( m \).
         iii. Let \( k=\lfloor f \rfloor \).
      c. Let \( a \) be the first \( k-f \) characters of \( m \), and let \( b \) be the remaining \( f \) characters of \( m \).
      d. Let \( m \) be the concatenation of the three Strings \( a ",", \) and \( b \).
      e. Let \( int \) be the number of characters in \( a \).
   5. Else let \( int \) be the number of characters in \( m \).
   6. Let \( cut \) be \( maxFraction - minFraction \).
   7. Repeat while \( cut > 0 \) and the last character of \( m \) is "0":
      a. Remove the last character from \( m \).
      b. Decrease \( cut \) by 1.
   8. If the last character of \( m \) is ",", then
      a. Remove the last character from \( m \).
   9. If \( int < nInteger \), then
      a. Let \( z \) be the String consisting of \( nInteger-int \) occurrences of the character "0".
      b. Let \( m \) be the concatenation of Strings \( z \) and \( m \).
10. Return \( m \).

### Table 2 – Numbering systems with simple digit mappings

### 12.3.3 `Intl.NumberFormat.prototype.resolvedOptions`

This named accessor property provides access to the locale and formatting options computed during initialization of the object.

The value of the `[Get]` attribute is a function that returns a new object with properties `locale`, `numberingSystem`, `style`, `currency`, `currencyDisplay`, `minimumIntegerDigits`, `minimumFractionDigits`, `maximumFractionDigits`, `minimumSignificantDigits`, `maximumSignificantDigits`, and `useGrouping`, each with the value of the corresponding internal property of this NumberFormat object (see 12.4). If the accessor is called on an object that does not have an `[[initializedNumberFormat]]` internal property with value true, then a TypeError is thrown.

The `[Set]` attribute is undefined.

### 12.4 Properties of `Intl.NumberFormat` Instances

`Intl.NumberFormat` instances inherit properties from the `Intl.NumberFormat` prototype object.

`Intl.NumberFormat` instances and other objects that have been successfully initialized as a NumberFormat have an `[[initializedNumberFormat]]` internal property whose value is true.

Objects that have been successfully initialized as a NumberFormat also have several internal properties that are computed by the constructor:

- `[[locale]]` is a String value with the language tag of the locale whose localization is used for formatting.
- `[[numberingSystem]]` is a String value with the "type" given in Unicode Technical Standard 35 for the numbering system used for formatting.
- `[[style]]` is one of the String values "decimal", "currency", or "percent", identifying the number format style used.
- `[[currency]]` is a String value with the currency code identifying the currency to be used if formatting with the "currency" style.
- `[[currencyDisplay]]` is one of the String values "code", "symbol", or "name", specifying whether to display the currency as an ISO 4217 alphabetic currency code, a localized currency symbol, or a localized currency name if formatting with the "currency" style.

</table>

The following steps are taken:

1. Let `options` be the result of calling the `ToDateTimeOptions` abstract operation with arguments `options`, `true`, and `false`.
2. Let `getOption` be the result of calling the `getGetOption` abstract operation with argument `options`.
3. Let `opt` be the result of creating a new object as if by the expression `new Object()` where `Object` is the standard built-in constructor with that name.
4. Let `matcher` be the result of calling `getOption` with the arguments `localeMatcher`, "string", ["lookup", "best fit"], and "best fit".
5. Set the `[localMatch][] internal property of opt to matcher`
6. Let `localeData` be the value of the `[localeData]` internal property of `Intl.DateTimeFormat`. 

© Ecma International 2012
7. Let $r$ be the result of calling the `ResolveLocale` abstract operation with the `[[availableLocales]]` internal property of `Intl.DateTimeFormat`, the `localeList` argument, `opt`, the `[[relevantExtensionKeys]]` internal property of `Intl.DateTimeFormat`, and `localeData`.

8. Set the `[[locale]]` internal property of `dateTimeFormat` to the value of the `[[locale]]` internal property of `r`.

9. Set the `[[calendar]]` internal property of `dateInfoFormatter` to the value of the `[[ca]]` internal property of `r`.

10. Set the `[[numberingSystem]]` internal property of `dateInfoFormatter` to the value of the `[[nu]]` internal property of `r`.

11. Let `localeData` be the value of the `[[data.locale]]` internal property of `r`.

12. Let `tz` be the result of calling the `[[Get]]` internal method of `options` with argument "`timeZone`".

13. If `tz` is `undefined`, then:
   a. Let `tz` be `ToString(tz)`.
   b. Convert `tz` to uppercase as described in 6.1.
   c. If `tz` is not equal to "UTC", then throw a `RangeError` exception.

14. Set the `[[timeZone]]` internal property of `dateTimeFormat` to `tz`.

15. Let `hr12` be the result of calling `getOption` with the arguments "`hour12`" and "`boolean`".

16. Let `dataLocaleDate` be the result of calling the `[[Get]]` internal method of `localeData` with argument `dataLocale`.

17. If `hr12` is `undefined`, then let `hr12` be the result of calling the `[[Get]]` internal method of `dataLocaleData` with argument "`hour12`".

18. Set the `[[hour12]]` internal property of `dateTimeFormat` to `hr12`.

19. Let `opt` be the result of creating a new object as if by the expression `new Object()` where `Object` is the standard built-in constructor with that name.

20. For each row of Table 3, except the header row, do:
   a. Let `prop` be the name given in the `Property` column of the row.
   b. Let `value` be the result of calling `getOption` with arguments `name` given in the `Property` column of the row, "string", and an array with the strings given in the `Values` column of the row.
   c. Set the `[[propName]]` internal property of `opt` to `value`.

21. Let `formats` be the result of calling the `[[Get]]` internal method of `dataLocaleData` with argument "`formats`".

22. Let `match` be the result of calling `getOption` with the arguments "`formatMatch`", "string", "["basic", "best fit"], and "best fit".

23. If `match` equals "basic" then:
   a. Let `bestFormat` be the result of calling `BestFitFormatMatch` with `opt` and `formats`.
   b. Else:
      a. Let `bestFormat` be the result of calling `BasicFormatMatch` with `opt` and `formats`.

24. For each row in Table 3, except the header row, do:
   a. Let `prop` be the name given in the `Property` column of the row.
   b. Let `pDesc` be the result of calling the `[[GetOwnProperty]]` internal method of `bestFormat` with argument `prop`.
   c. If `pDesc` is not `undefined`, then:
      i. Let `p` be the result of calling the `[[Get]]` internal method of `bestFormat` with argument `prop`.
      ii. Let `r` be the result of calling the `[[Get]]` internal method of `pattern` to `p`.

25. Set the `[[pattern]]` internal property of `dateTimeFormat` to `pattern`.

26. Set the `[[initializedDateTimeFormat]]` internal property of `dateTimeFormat` to `true`.

When the `ToDateTimeOptions` abstract operation is called with arguments `options`, `date`, and `time`, the following steps are taken:

1. If `options` is not supplied or is `undefined`, then let `options` be `null`, else let `options` be `ToObject(options)`.

2. Let `create` be the standard built-in function object defined in ES5, `Object`. If `create` is not a function, then throw an `InternalError` exception.

3. Let `options` be the result of calling the `[[Call]]` internal method of `create` with `undefined` as the this value and an argument list containing the single item `options`.

4. Let `needDefault` be `true`.

5. If `date` equals `true`, then:
   a. For each of the property names "`weekday`", "`year`", "`month`", "`day`":
      i. If the result of calling the `[[Get]]` internal method of `options` with the property name is not `undefined`, then let `needDefault` be `false`.

6. If `time` equals `true`, then:
   a. For each of the property names "`hour`", "`minute`", "`second`":
      i. If the result of calling the `[[Get]]` internal method of `options` with the property name is not `undefined`, then let `needDefault` be `false`.

© Ecma International 2012
7. If needDefault and date both equal true, then:
   a. For each of the property names "year", "month", "day":
      i. Call the [[DefineOwnProperty]] internal method of options with the property name, Property
         Descriptor {[[Value]]: "numeric", [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: 
         true}, and true.
8. If needDefault and time both equal true, then:
   a. For each of the property names "hour", "minute", "second":
      i. Call the [[DefineOwnProperty]] internal method of options with the property name, Property
         Descriptor {[[Value]]: "numeric", [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: 
         true}, and true.
9. Return options.

When the BasicFormatMatch abstract operation is called with two arguments options and formats, the
following steps are taken:

1. Let removalPenalty be 120.
2. Let additionPenalty be 20.
5. Let shortMorePenalty be 3.
7. Let bestScore be Infinity.
8. Let bestFormat be undefined.
9. Let i be 0.
10. Repeat while i < len:
    a. Let eachFormat be the result of calling the [[Get]] internal method of formats, with argument "length".
    b. Let score be 0.
    c. For each property shown in Table 3:
       i. Let optionsProp be the result of calling the [[Get]] internal method of options, with argument property.
       ii. Let formatPropDesc be the result of calling the [[GetOwnProperty]] internal method of format, with argument
           property.
       iii. If formatPropDesc is not undefined, then
           1. Let formatProp be the result of calling the [[Get]] internal method of format, with argument
              property.
           iv. If optionsProp is undefined and formatProp is not undefined, then decrease score by
               additionPenalty.
           v. Else if optionsProp is not undefined and formatProp is undefined, then decrease score by
              removalPenalty.
           vi. Else
               1. Let values be the array ["2-digit", "numeric", "narrow", "short", "long"].
               2. Let optionsPropIndex be the index of optionsProp within values.
               3. Let formatPropIndex be the index of formatProp within values.
               4. Let delta be max(min(formatPropIndex - optionsPropIndex, 2), -2).
               5. If delta < 2, decrease score by longMorePenalty.
               6. Else if delta < -1, decrease score by shortMorePenalty.
               7. Else if delta < -2, decrease score by longLessPenalty.
               8. Else if delta > 2, decrease score by shortLessPenalty.
    d. If score < bestScore, then
       i. Let bestScore be score.
       ii. Let bestFormat be format.
    e. Increase i by 1.

When the BestFitFormatMatch abstract operation is called with two arguments options and formats, it
performs implementation dependent steps, which should return a set of component representations that a
typical user of the selected locale would perceive as at least as good as the one returned by 
BasicFormatMatch.

### 13.1.2 The Intl.DateTimeFormat Constructor Called as a Function

When Intl.DateTimeFormat is called as a function rather than as a constructor, it accepts the optional 
arguments `localeList` and `options` and takes the following steps:

1. If this is the Intl object or `undefined`, then
   a. Return the result of creating a new object as if by the expression new
      Intl.DateTimeFormat(localeList, options), where Intl.DateTimeFormat is the standard 
built-in constructor defined in 13.1.3;
2. Let obj be the result of calling ToObject passing the `this` value as the argument.
3. Call the InitializeDateTimeFormat abstract operation with arguments `obj`, `localeList`, and `options`.
4. Return `obj`.

### 13.1.3 The Intl.DateTimeFormat Constructor Used in a new Expression

When Intl.DateTimeFormat is called as part of a new expression, it is a constructor. It accepts the optional 
arguments `localeList` and `options`, and initializes the properties of the newly constructed object by calling the 
InitializeDateTimeFormat abstract operation (1.1.1), passing the newly constructed object, `localeList`, and 
`options` as arguments.

The `[[Prototype]]` internal property of the newly constructed object is set to the original `Intl.DateTimeFormat` 
prototype object, the one that is the value of `Intl.DateTimeFormat.prototype` (13.2.1). 

The `[[Extensible]]` internal property of the newly constructed object is set to true.

### 13.2 Properties of the Intl.DateTimeFormat Constructor

Besides the internal properties and the length property (whose value is 2), the `Intl.DateTimeFormat` 
constructor has the following properties:

#### 13.2.1 `Intl.DateTimeFormat.prototype`

The value of `Intl.DateTimeFormat.prototype` is the built-in `Intl.DateTimeFormat` prototype object (13.3). This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

#### 13.2.2 `Intl.DateTimeFormat.supportedLocalesOf(requestedLocales [, options])`

When the `supportedLocalesOf` method of `Intl.DateTimeFormat` is called, the following steps are taken:

1. Let `availableLocales` be the value of the `[[availableLocales]]` internal property of `Intl.DateTimeFormat`.
2. Return the result of calling the `supportedLocales abstract operation with arguments availableLocales`, `requestedLocales`, and `options`.

#### 13.2.3 Internal Properties

The value of the `[[availableLocales]]` internal property is implementation dependent within the constraints 
described in 10.1.

The value of the `[[relevantExtensionKeys]]` internal property is `"ca", "nu"`.

NOTE Unicode Technical Standard 35 describes three locale extension keys that are relevant to date and time 
formatting: "ca" for calendar, "tz" for time zone, and implicitly "nu" for the numbering system of the number format used for 
numbers within the date format. DateTimeFormat, however, requires that the time zone is specified through the timeZone 
property in the options objects.
The value of the [[localeData]] internal property is implementation dependent within the constraints described in 10.1 and the following additional constraints:

- [[localeData]][locale] must have an hour12 property with a Boolean value for all locale values.
- [[localeData]][locale] must have a formats property for all locale values. The value of this property must be an array of objects, each of which has a subset of the properties shown in Table 3, where each property must have one of the values specified for the property in Table 3. Multiple objects in an array may use the same subset of the properties as long as they have different values for the properties. The following subsets must be available for each locale:
  - weekday, year, month, day, hour, minute, second
  - weekday, year, month, day
  - year, month
  - year, month, day
  - year, month, day, hour, minute
  - hour, minute

Each of the objects must also have a pattern property, whose value is a String value that contains for each of the date and time format component properties of the object a substring starting with "{", followed by the name of the property, followed by "}".

EXAMPLE  An implementation might include the following object as part of its English locale data: {hour: "numeric", minute: "2-digit", second: "2-digit", pattern: "(hour):(minute):(second)"}.

## 13.3 Properties of the Intl.DateTimeFormat Prototype Object

The Intl.DateTimeFormat prototype object is itself an Intl.DateTimeFormat instance as specified in 13.4, whose internal properties are set as if it had been constructed by the expression `new Intl.DateTimeFormat()`.

In the following descriptions of functions that are properties of the Intl.DateTimeFormat prototype object, the phrase “this DateTimeFormat object” refers to the object that is the this value for the invocation of the function.

### 13.3.1 Intl.DateTimeFormat.prototype.constructor

The initial value of Intl.DateTimeFormat.prototype.constructor is the built-in Intl.DateTimeFormat constructor.

### 13.3.2 Intl.DateTimeFormat.prototype.format ([date])

Returns a String value representing the result of calling ToNumber(date) according to the effective locale and the formatting options of this DateTimeFormat object. The computation uses the abstract operation ToLocalTime (defined below). The result of calling ToNumber(date) is interpreted as a time value as specified in ES5, 15.9.1.1, or successor.

1. If this DateTimeFormat object does not have an [[initializedDateTimeFormat]] internal property with value true, then throw a TypeError exception.
2. If date is omitted let y be Date.now(); else let y be ToNumber(date).
3. If y is not a finite Number, then throw a RangeError exception.
4. Let locale be the value of the [[locale]] internal property of this DateTimeFormat object.
5. Let y2 be the result of creating a new NumberFormat object as if by the expression `new Intl.NumberFormat([[locale]])` where Intl.NumberFormat is the standard built-in constructor defined in 12.1.3.
6. Let y2 be the result of creating a new NumberFormat object as if by the expression `new Intl.NumberFormat([[locale]], {minimumIntegerDigits: 2})` where Intl.NumberFormat is the standard built-in constructor defined in 12.1.3.
7. Let tm be the result of calling ToLocalTime with y, the value of the [[calendar]] internal property of this DateTimeFormat object, and the value of the [[timeZone]] internal property of this DateTimeFormat object.
8. Let result be the value of the [[pattern]] internal property of this DateTimeFormat object.
9. For each row of Table 3, except the header row, do:
a. If this DateTimeFormat object has an internal property with the name given in the Property column of the row, then:
   i. Let p be the name given in the Property column of the row.
   ii. Let f be the value of the [p] internal property of this DateTimeFormat object.
   iii. Let v be the value of the [f] internal property of f.
   iv. If f equals "month", then increase v by 1.
   v. Let format be the standard built-in function object defined in 12.3.2.
   vi. If f equals "numeric", then
      1. Let f be the result of calling the [[Call]] method of format with v as the this value and an argument list containing the single item v.
      2. If the length of f is greater than 2, let f be the substring of f containing the last two characters.
   vii. Else if f equals "2-digit", then
      1. Let f be the result of calling the [[Call]] method of format with v/2 as the this value and an argument list containing the single item v.
      2. Replace the substring of result that consists of "*", "p", and "+", with f.
   viii. Else if f equals "narrow", "short", or "long", then let f be an implementation, locale, and calendar dependent String value representing f in the desired form. If f equals "month", then the String value may also depend on whether this DateTimeFormat object has a day property. If f equals "timeZoneName", then the String value may also depend on the value of the isDST property of m.
   ix. Replace the substring of result that consists of "*", "p", and "+", with f.

10. Return result.

When the abstract operation ToLocalTime is called with arguments date, calendar, and timeZone, the following steps are taken:

1. Apply calendrical calculations on date for the given calendar and time zone to produce weekday, era, year, month, day, hour, minute, second, and inDST values. The calculations should use best available information about the specified calendar and time zone. If the calendar is "gregory", then the calculations must match the algorithms specified in ES5, 15.9.1, except that calculations are not bound by the restrictions on the use of best available information on time zones for local time zone adjustment and daylight saving time adjustment imposed by ES5, 15.9.1.7 and 15.9.1.8.
2. Return an object with internal properties [[weekday]], [[era]], [[year]], [[month]], [[day]], [[hour]], [[minute]], [[second]], and [[inDST]], each with the corresponding calculated value.

NOTE It is recommended that implementations use the time zone information of the JANA Time Zone Database.

13.3.3 Intl.DateTimeFormat.prototype.resolvedOptions

This named accessor property provides access to the locale and formatting options computed during initialization of the object.

The value of the [[Get]] attribute is a function that returns a new object with properties locale, calendar, numberingSystem, timeZone, hour12, weekday, era, year, month, day, hour, minute, second, and timeZoneName, each with the value of the corresponding internal property of this DateTimeFormat object (see 13.4). If the accessor is called on an object that does not have an [[InitializedDateTimeFormat]] internal property with value true, then a TypeError is thrown.

The [[Set]] attribute is undefined.

NOTE In this version of the ECMA-Script Internationalization API, the timeZone property will remain undefined if no timeZone property was provided in the options object provided to the Intl.DateTimeFormat constructor. However, applications should not rely on this, as future versions may return a String value identifying the host environment’s current time zone instead.

13.4 Properties of Intl.DateTimeFormat Instances

Intl.DateTimeFormat instances inherit properties from the Intl.DateTimeFormat prototype object.
Intl.DateTimeFormat instances and other objects that have been successfully initialized as a DateTimeFormat have an [[initializedDateTimeFormat]] internal property whose value is true.

Objects that have been successfully initialized as a DateTimeFormat also have several internal properties that are computed by the constructor:

- [[locale]] is a String value with the language tag of the locale whose localization is used for formatting.
- [[calendar]] is a String value with the "type" given in Unicode Technical Standard 35 for the calendar used for formatting.
- [[numberingSystem]] is a String value with the "type" given in Unicode Technical Standard 35 for the numbering system used for formatting.
- [[timeZone]] is either the String value "UTC" or undefined.
- [[hour12]] is a Boolean value indicating whether 12-hour format (true) or 24-hour format (false) should be used.
- [[weekday]], [[era]], [[year]], [[month]], [[day]], [[hour]], [[minute]], [[second]], [[timeZoneName]] are each either undefined, indicating that the component is not used for formatting, or one of the String values given in Table 3, indicating how the component should be presented in the formatted output.
- [[pattern]] is a String value as described in 13.2.3.

14 Locale Sensitive Functions of the ECMAScript Language Specification

The ECMAScript Language Specification, edition 5.1 or successor, describes several locale sensitive functions. An ECMAScript implementation that implements this Internationalization API shall implement these functions as described here.

14.1 Properties of the String Prototype Object

14.1.1 String.prototype.localeCompare (that [, localeList [, options]])

When the localeCompare method is called with arguments that, localeList, and options, the following steps are taken:

1. Let collator be the result of creating a new object as if by the expression new Intl.Collator(localeList, options) where Intl.Collator is the standard built-in constructor defined in 13.1.3.
2. Return the result of calling the Compare abstract operation with arguments collator, this, and that.

14.2 Properties of the Number Prototype Object

14.2.1 Number.prototype.toLocaleString ([localeList [, options]])

When the toLocaleString method is called with arguments localeList and options, the following steps are taken:

1. Let numberFormat be the result of creating a new object as if by the expression new Intl.NumberFormat(localeList, options) where Intl.NumberFormat is the standard built-in constructor defined in 12.1.3.
2. Let format be the standard built-in function object defined in 12.3.2.
3. Return the result of calling the [[Call]] internal method of format with numberFormat as the this value and an argument list containing the single item this.

14.3 Properties of the Date Prototype Object

The properties of the Date prototype object described here use the abstract operation ToDateTimeOptions, specified in 1.1.1.
14.3.1 Date.prototype.toLocaleString ([localeList [, options]])

When the toLocaleString method is called with arguments localeList and options, the following steps are taken:

1. Let options be the result of calling the ToDateTimeOptions abstract operation with arguments options, true, and true.
2. Let dateTimeFormat be the result of creating a new object as if by the expression new Intl.DateTimeFormat (localeList, options) where Intl.DateTimeFormat is the standard built-in constructor defined in 13.1.3.
3. Let format be the standard built-in function object defined in 13.3.2.
4. Return the result of calling the [[Call]] internal method of format with dateTimeFormat as the this value and an argument list containing the single item this.

14.3.2 Date.prototype.toLocaleDateString ([localeList [, options]])

When the toLocaleDateString method is called with arguments localeList and options, the following steps are taken:

1. Let options be the result of calling the ToDateTimeOptions abstract operation with arguments options, true, and false.
2. Let dateTimeFormat be the result of creating a new object as if by the expression new Intl.DateTimeFormat (localeList, options) where Intl.DateTimeFormat is the standard built-in constructor defined in 13.1.3.
3. Let format be the standard built-in function object defined in 13.3.2.
4. Return the result of calling the [[Call]] internal method of format with dateTimeFormat as the this value and an argument list containing the single item this.

14.3.3 Date.prototype.toLocaleTimeString ([localeList [, options]])

When the toLocaleTimeString method is called with arguments localeList and options, the following steps are taken:

1. Let options be the result of calling the ToDateTimeOptions abstract operation with arguments options, false, and true.
2. Let dateTimeFormat be the result of creating a new object as if by the expression new Intl.DateTimeFormat (localeList, options) where Intl.DateTimeFormat is the standard built-in constructor defined in 13.1.3.
3. Let format be the standard built-in function object defined in 13.3.2.
4. Return the result of calling the [[Call]] internal method of format with dateTimeFormat as the this value and an argument list containing the single item this.
