Introduction

This Ecma Standard is based on several originating technologies, the most well known being JavaScript (Netscape) and JScript (Microsoft). The language was invented by Brendan Eich at Netscape and first appeared in that company’s Navigator 2.0 browser. It has appeared in all subsequent browsers from Netscape and in all browsers from Microsoft starting with Internet Explorer 3.0.

The development of this Standard started in November 1996. The first edition of this Ecma Standard was adopted by the Ecma General Assembly of June 1997.

That Ecma Standard was submitted to ISO/IEC JTC 1 for adoption under the fast-track procedure, and approved as international standard ISO/IEC 16262, in April 1998. The Ecma General Assembly of June 1998 approved the second edition of ECMAScript to keep it fully aligned with ISO/IEC 16262. Changes between the first and the second edition are editorial in nature.

Since publication of the third edition, ECMAScript has achieved massive adoption in conjunction with the World Wide Web where it has become the programming language that is supported by essentially all web browsers. Significant work was done to develop a fourth edition of ECMAScript. Although that work was not completed and not published as the fourth edition of ECMAScript, it informs continuing evolution of the language. The fifth edition of ECMAScript (published as ECMA-262 5th edition) codifies de facto interpretations of the language specification that have become common among browser implementations and adds support for new features that have emerged since the publication of the third edition. Such features include accessor properties, reflective creation and inspection of objects, program control of property attributes, additional array manipulation functions, support for the JSON object encoding format, and a strict mode that provides enhanced error checking and program security.

The edition 5.1 of the ECMAScript Standard has been fully aligned with the third edition of the international standard ISO/IEC 16262:2011.

This present sixth edition of the Standard………

ECMAScript is a vibrant language and the evolution of the language is not complete. Significant technical enhancement will continue with future editions of this specification.

This Ecma Standard has been adopted by the General Assembly of <month> <year>.

---

1 Note: Please note that for ECMAScript Edition 4 the Ecma standard number “ECMA-262 Edition 4” was reserved but not used in the Ecma publication process. Therefore “ECMA-262 Edition 4” as an Ecma International publication does not exist.
"DISCLAIMER

This draft document may be copied and furnished to others, and derivative works that comment on or otherwise explain it or assist in its implementation may be prepared, copied, published, and distributed, in whole or in part, without restriction of any kind, provided that the above copyright notice and this section are included on all such copies and derivative works. However, this document itself may not be modified in any way, including by removing the copyright notice or references to Ecma International, except as needed for the purpose of developing any document or deliverable produced by Ecma International.

This disclaimer is valid only prior to final version of this document. After approval all rights on the standard are reserved by Ecma International.

ECMAScript Language Specification

1 Scope
This Standard defines the ECMAScript scripting language.

2 Conformance
A conforming implementation of ECMAScript must provide and support all the types, values, objects, properties, functions, and program syntax and semantics described in this specification.

A conforming implementation of this Standard shall interpret characters in conformance with the Unicode Standard, Version 5.1.0 or later and ISO/IEC 10646. If the adopted ISO/IEC 10646-1 subset is not otherwise specified, it is presumed to be the Unicode set, collection 10646.

A conforming implementation of ECMAScript is permitted to provide additional types, values, objects, properties, and functions beyond those described in this specification. In particular, a conforming implementation of ECMAScript is permitted to provide properties not described in this specification, and values for those properties, for objects that are described in this specification.

A conforming implementation of ECMAScript is permitted to provide additional types, values, objects, properties, and functions beyond those described in this specification. In particular, a conforming implementation of ECMAScript is permitted to support program syntax that makes use of the “future reserved words” listed in 11.6.1.2 of this specification.

3 Normative references
The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO/IEC 9899:1996, Programming Languages – C, including amendment 1 and technical corrigenda 1 and 2

The Unicode Standard, Version 5.0, as amended by Unicode 5.1.0, or successor

Unicode Standard Annex #15, Unicode Normalization Forms, version Unicode 5.1.0, or successor

Unicode Standard Annex #31, Unicode Identifiers and Pattern Syntax, version Unicode 5.1.0, or successor.

4 Overview
This section contains a non-normative overview of the ECMAScript language.

ECMAScript is an object-oriented programming language for performing computations and manipulating computational objects within a host environment. ECMAScript as defined here is not intended to be computationally self-sufficient; indeed, there are no provisions in this specification for input of external data or output of computed results. Instead, it is expected that the computational environment of an ECMAScript program will provide not only the objects and other facilities described in this specification but also certain environment-specific objects, whose description and behaviour are beyond the scope of this specification except to indicate that they may provide certain properties that can be accessed and certain functions that can be called from an ECMAScript program.
A scripting language is a programming language that is used to manipulate, customise, and automate the facilities of an existing system. In such systems, useful functionality is already available through a user interface, and the scripting language is a mechanism for exposing that functionality to program control. In this way, the existing system is said to provide a host environment of objects and facilities, which completes the capabilities of the scripting language. A scripting language is intended for use by both professional and non-professional programmers. ECMAScript was originally designed to be used as a scripting language, but has become widely used as a general purpose programming language.

ECMAScript was originally designed to be used as a scripting language, providing a mechanism to enliven Web pages in browsers and to perform server computation as part of a Web-based client-server architecture. ECMAScript is now used both as a general propose programming language and to provide core scripting capabilities for a variety of host environments. Therefore the core language is specified in this document apart from any particular host environment.

Some of the facilities of ECMAScript are similar to those used in other programming languages; in particular Java™, Self, and Scheme as described in:

4.1 Web Scripting

A web browser provides an ECMAScript host environment for client-side computation including, for instance, objects that represent windows, menus, pop-ups, dialog boxes, text areas, anchors, frames, history, cookies, and input/output. Further, the host environment provides a means to attach scripting code to events such as change of focus, page and image loading, unloading, error and abort, selection, form submission, and mouse actions. Scripting code appears within the HTML and the displayed page is a combination of user interface elements and fixed and computed text and images. The scripting code is reactive to user interaction and there is no need for a main program.

A web server provides a different host environment for server-side computation including objects representing requests, clients, and files; and mechanisms to lock and share data. By using browser-side and server-side scripting together, it is possible to distribute computation between the client and server while providing a customised user interface for a Web-based application.

Each Web browser and server that supports ECMAScript supplies its own host environment, completing the ECMAScript execution environment.

4.2 ECMAScript Overview

The following is an informal overview of ECMAScript—not all parts of the language are described. This overview is not part of the standard proper.

ECMAScript is object-based: basic language and host facilities are provided by objects, and an ECMAScript program is a cluster of communicating objects. An ECMAScript object is a collection of properties each with zero or more attributes that determine how each property can be used—for example, when the Writable attribute for a property is set to false, any attempt by executed ECMAScript code to change the value of the property fails. Properties are containers that hold other objects, primitive values, or functions. A primitive value is a member of one of the following built-in types: Undefined, Null, Boolean, Number, and String; an object is a member of the remaining built-in type Object; and a function is a callable object. A function that is associated with an object via a property is a method.

ECMAScript defines a collection of built-in objects that round out the definition of ECMAScript entities. These built-in objects include the global object, the Object object, the Function object, the Array object, the String
object, the Boolean object, the Number object, the Math object, the Date object, the RegExp object, the JSON object, and the Error objects Error, EvalError, RangeError, ReferenceError, SyntaxError, TypeError and URIError.

ECMAScript also defines a set of built-in operators. ECMAScript operators include various unary operations, multiplicative operators, additive operators, bitwise shift operators, relational operators, equality operators, binary bitwise operators, binary logical operators, assignment operators, and the comma operator.

ECMAScript syntax intentionally resembles Java syntax. ECMAScript syntax is relaxed to enable it to serve as an easy-to-use scripting language. For example, a variable is not required to have its type declared nor are types associated with properties, and defined functions are not required to have their declarations appear textually before calls to them.

4.2.1 Objects

ECMAScript does not use classes such as those in C++, Smalltalk, or Java. Instead objects may be created in various ways including via a literal notation or via constructors which create objects and then execute code that initialises all or part of them by assigning initial values to their properties. Each constructor is a function that has a property named ’prototype’ that is used to implement prototype-based inheritance and shared properties. Objects are created by using constructors in new expressions; for example, new Date(2009,11) creates a new Date object. Invoking a constructor without using new has consequences that depend on the constructor. For example, Date() produces a string representation of the current date and time rather than an object.

Every object created by a constructor has an implicit reference (called the object’s prototype) to the value of its constructor’s ’prototype’ property. Furthermore, a prototype may have a non-null implicit reference to its prototype, and so on; this is called the prototype chain. When a reference is made to a property in an object, that reference is to the property of that name in the first object in the prototype chain that contains a property of that name. In other words, first the object mentioned directly is examined for such a property; if that object contains the named property, that is the property to which the reference refers; if that object does not contain the named property, the prototype for that object is examined next; and so on.

![Diagram of Object/Prototype Relationships](image)

**Figure 1 — Object/Prototype Relationships**

In a class-based object-oriented language, in general, state is carried by instances, methods are carried by classes, and inheritance is only of structure and behaviour. In ECMAScript, the state and methods are carried by objects, while structure, behaviour, and state are all inherited.
All objects that do not directly contain a particular property that their prototype contains share that property and its value. Figure 1 illustrates this:

CF is a constructor (and also an object). Five objects have been created by using new expressions: cf1, cf2, cf3, cf4, and cf5. Each of these objects contains properties named q1 and q2. The dashed lines represent the implicit prototype relationship; so, for example, cf1’s prototype is CF. The constructor, CF, has two properties itself, named p1 and p2, which are not visible to CFp, cf1, cf2, cf3, cf4, or cf5. The property named CFP1 in CFp is shared by cf1, cf2, cf3, cf4, and cf5 (but not by CF), as are any properties found in CFp’s implicit prototype chain that are not named q1, q2, or CFP1. Notice that there is no implicit prototype link between CF and CFp.

Unlike class-based object languages, properties can be added to objects dynamically by assigning values to them. That is, constructors are not required to name or assign values to all or any of the constructed object’s properties. In the above diagram, one could add a new shared property for cf1, cf2, cf3, cf4, and cf5 by assigning a new value to the property in CFp.

4.2.2 The Strict Variant of ECMAScript

The ECMAScript Language recognises the possibility that some users of the language may wish to restrict their usage of some features available in the language. They might do so in the interests of security, to avoid what they consider to be error-prone features, to get enhanced error checking, or for other reasons of their choosing. In support of this possibility, ECMAScript defines a strict variant of the language. The strict variant of the language excludes some specific syntactic and semantic features of the regular ECMAScript language and modifies the detailed semantics of some features. The strict variant also specifies additional error conditions that must be reported by throwing error exceptions in situations that are not specified as errors by the non-strict form of the language.

The strict variant of ECMAScript is commonly referred to as the strict mode of the language. Strict mode selection and use of the strict mode syntax and semantics of ECMAScript is explicitly made at the level of individual ECMAScript code units. Because strict mode is selected at the level of a syntactic code unit, strict mode only imposes restrictions that have local effect within such a code unit. Strict mode does not restrict or modify any aspect of the ECMAScript semantics that must operate consistently across multiple code units. A complete ECMAScript program may be composed for both strict mode and non-strict mode ECMAScript code units. In this case, strict mode only applies when actually executing code that is defined within a strict mode code unit.

In order to conform to this specification, an ECMAScript implementation must implement both the full unrestricted ECMAScript language and the strict mode variant of the ECMAScript language as defined by this specification. In addition, an implementation must support the combination of unrestricted and strict mode code units into a single composite program.

4.3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

4.3.1 type
set of data values as defined in Clause 8 of this specification

4.3.2 primitive value
member of one of the types Undefined, Null, Boolean, Number, or String as defined in Clause 8

NOTE A primitive value is a datum that is represented directly at the lowest level of the language implementation.

4.3.3 object
member of the type Object

NOTE An object is a collection of properties and has a single prototype object. The prototype may be the null value.
4.3.4 constructor
function object that creates and initialises objects

NOTE The value of a constructor's "prototype" property is a prototype object that is used to implement inheritance and shared properties.

4.3.5 prototype
object that provides shared properties for other objects

NOTE When a constructor creates an object, that object implicitly references the constructor's "prototype" property for the purpose of resolving property references. The constructor's "prototype" property can be referenced by the program expression constructor.prototype, and properties added to an object's prototype are shared, through inheritance, by all objects sharing the prototype. Alternatively, a new object may be created with an explicitly specified prototype by using the Object.create built-in function.

4.3.6 ordinary object
object that has the default behaviour for the internal methods that must be supported by all ECMAScript objects.

4.3.7 exotic object
object that has some alternative behaviour for one or more of the internal methods that must be supported by all ECMAScript objects.

NOTE Any object that is not an ordinary object is an exotic object.

4.3.8 standard object
object whose semantics are defined by this specification.

4.3.9 built-in object
object supplied by an ECMAScript implementation, independent of the host environment, that is present at the start of the execution of an ECMAScript program.

NOTE Standard built-in objects are defined in this specification, and an ECMAScript implementation may specify and define others. A built-in constructor is a built-in object that is also a constructor.

4.3.10 undefined value
primitive value used when a variable has not been assigned a value

4.3.11 Undefined type
type whose sole value is the undefined value

4.3.12 null value
primitive value that represents the intentional absence of any object value

4.3.13 Null type
type whose sole value is the null value

4.3.14 Boolean value
member of the Boolean type
NOTE There are only two Boolean values, true and false.

4.3.15
Boolean type
type consisting of the primitive values true and false

4.3.16
Boolean object
member of the Object type that is an instance of the standard built-in Boolean constructor

NOTE A Boolean object is created by using the Boolean constructor in a new expression, supplying a Boolean value as an argument. The resulting object has an internal data property whose value is the Boolean value. A Boolean object can be coerced to a Boolean value.

4.3.17
String value
primitive value that is a finite ordered sequence of zero or more 16-bit unsigned integer.

NOTE A String value is a member of the String type. Each integer value in the sequence usually represents a single 16-bit unit of UTF-16 text. However, ECMAScript does not place any restrictions or requirements on the values except that they must be 16-bit unsigned integers.

4.3.18
String type
set of all possible String values

4.3.19
String object
member of the Object type that is an instance of the standard built-in String constructor

NOTE A String object is created by using the String constructor in a new expression, supplying a String value as an argument. The resulting object has an internal data property whose value is the String value. A String object can be coerced to a String value by calling the String constructor as a function (21.1.1.1).

4.3.20
Number value
primitive value corresponding to a double-precision 64-bit binary format IEEE 754 value

NOTE A Number value is a member of the Number type and is a direct representation of a number.

4.3.21
Number type
set of all possible Number values including the special “Not-a-Number” (NaN) value, positive infinity, and negative infinity

4.3.22
Number object
member of the Object type that is an instance of the standard built-in Number constructor

NOTE A Number object is created by using the Number constructor in a new expression, supplying a Number value as an argument. The resulting object has an internal data property whose value is the Number value. A Number object can be coerced to a Number value by calling the Number constructor as a function (20.1.1.1).

4.3.23
Infinity
number value that is the positive infinite Number value

4.3.24
NaN
number value that is a IEEE 754 “Not-a-Number” value
4.3.25
function
member of the Object type that may be invoked as a subroutine

NOTE In addition to its properties, a function contains executable code and state that determine how it behaves when invoked. A function’s code may or may not be written in ECMAScript.

4.3.26
built-in function
built-in object that is a function

NOTE Examples of built-in functions include parseInt and Math.exp. An implementation may provide implementation-dependent built-in functions that are not described in this specification.

4.3.27
property
association between a name and a value that is a part of an object

NOTE Depending upon the form of the property the value may be represented either directly as a data value (a primitive value, an object, or a function object) or indirectly by a pair of accessor functions.

4.3.28
method
function that is the value of a property

NOTE When a function is called as a method of an object, the object is passed to the function as its this value.

4.3.29
built-in method
method that is a built-in function

NOTE Standard built-in methods are defined in this specification, and an ECMAScript implementation may specify and provide other additional built-in methods.

4.3.30
attribute
internal value that defines some characteristic of a property

4.3.31
own property
property that is directly contained by its object

4.3.32
inherited property
property of an object that is not an own property but is a property (either own or inherited) of the object's prototype

4.4 Organization of This Specification

The remainder of this specification is organized as follows:

Clause 5 defines the notational conventions used throughout the specification.

Clauses 6-9 define the execution environment within which ECMAScript programs operate.

Clauses 10-16 define the actual ECMAScript programming language including its syntactic encoding and the execution semantics of all language features.

Clauses 17-26 define the ECMAScript standard library. It includes the definitions of all of the standard objects that are available for use by ECMAScript programs as the execute.
5 Notational Conventions

5.1 Syntactic and Lexical Grammars

5.1.1 Context-Free Grammars

A context-free grammar consists of a number of productions. Each production has an abstract symbol called a nonterminal as its left-hand side, and a sequence of zero or more nonterminal and terminal symbols as its right-hand side. For each grammar, the terminal symbols are drawn from a specified alphabet.

A chain production is a production that has exactly one nonterminal symbol on its right-hand side along with zero or more terminal symbols.

Starting from a sentence consisting of a single distinguished nonterminal, called the goal symbol, a given context-free grammar specifies a language, namely, the (perhaps infinite) set of possible sequences of terminal symbols that can result from repeatedly replacing any nonterminal in the sequence with a right-hand side of a production for which the nonterminal is the left-hand side.

5.1.2 The Lexical and RegExp Grammars

A lexical grammar for ECMAScript is given in clause 7. This grammar has as its terminal symbols characters (Unicode code units) that conform to the rules for SourceCharacter defined in Clause 6. It defines a set of productions, starting from the goal symbol InputElementDiv or InputElementRegExp, that describe how sequences of such characters are translated into a sequence of input elements.

Input elements other than white space and comments form the terminal symbols for the syntactic grammar for ECMAScript and are called ECMAScript tokens. These tokens are the reserved words, identifiers, literals, and punctuators of the ECMAScript language. Moreover, line terminators, although not considered to be tokens, also become part of the stream of input elements and guide the process of automatic semicolon insertion (11.9). Simple white space and single-line comments are discarded and do not appear in the stream of input elements for the syntactic grammar. A MultiLineComment (that is, a comment of the form "/* ... */" regardless of whether it spans more than one line) is likewise simply discarded if it contains no line terminator; but if a MultiLineComment contains one or more line terminators, then it is replaced by a single line terminator, which becomes part of the stream of input elements for the syntactic grammar.

A RegExp grammar for ECMAScript is given in 21.2.1. This grammar also has as its terminal symbols the characters as defined by SourceCharacter. It defines a set of productions, starting from the goal symbol Pattern, that describe how sequences of characters are translated into regular expression patterns.

Productions of the lexical and RegExp grammars are distinguished by having two colons `::` as separating punctuation. The lexical and RegExp grammars share some productions.

5.1.3 The Numeric String Grammar

Another grammar is used for translating Strings into numeric values. This grammar is similar to the part of the lexical grammar having to do with numeric literals and has as its terminal symbols SourceCharacter. This grammar appears in 7.1.3.1.

Productions of the numeric string grammar are distinguished by having three colons `:::` as punctuation.

5.1.4 The Syntactic Grammar

The syntactic grammar for ECMAScript is given in clauses 11, 12, 13 and 14. This grammar has ECMAScript tokens defined by the lexical grammar as its terminal symbols (5.1.2). It defines a set of productions, starting from the goal symbol Script, that describe how sequences of tokens can form syntactically correct independent components of an ECMAScript programs.
When a stream of characters is to be parsed as an ECMAScript script, it is first converted to a stream of input elements by repeated application of the lexical grammar; this stream of input elements is then parsed by a single application of the syntactic grammar. The script is syntactically in error if the tokens in the stream of input elements cannot be parsed as a single instance of the goal nonterminal Script, with no tokens left over.

Productions of the syntactic grammar are distinguished by having just one colon "::" as punctuation.

The syntactic grammar as presented in clauses 12, 13, 14 and 15 is actually not a complete account of which token sequences are accepted as correct ECMAScript scripts. Certain additional token sequences are also accepted, namely, those that would be described by the grammar if only semicolons were added to the sequence in certain places (such as before line terminator characters). Furthermore, certain token sequences that are described by the grammar are not considered acceptable if a terminator character appears in certain "awkward" places.

In certain cases in order to avoid ambiguities the syntactic grammar uses generalised productions that permit token sequences that are not valid ECMAScript scripts. For example, this technique is used in with object literals and object destructuring patterns. In such cases a more restrictive supplemental grammar is provided that further restricts the acceptable token sequences. In certain contexts, when explicitly specific, the input elements corresponding to such a production are parsed again using a goal symbol of a supplemental grammar. The script is syntactically in error if the tokens in the stream of input elements cannot be parsed as a single instance of the supplemental goal symbol, with no tokens left over.

5.1.5 The JSON Grammar

The JSON grammar is used to translate a String describing a set of ECMAScript objects into actual objects. The JSON grammar is given in 24.3.1.

The JSON grammar consists of the JSON lexical grammar and the JSON syntactic grammar. The JSON lexical grammar is used to translate character sequences into tokens and is similar to parts of the ECMAScript lexical grammar. The JSON syntactic grammar describes how sequences of tokens from the JSON lexical grammar can form syntactically correct JSON object descriptions.

Productions of the JSON lexical grammar are distinguished by having two colons "::" as separating punctuation. The JSON lexical grammar uses some productions from the ECMAScript lexical grammar. The JSON syntactic grammar is similar to parts of the ECMAScript syntactic grammar. Productions of the JSON syntactic grammar are distinguished by using one colon "::" as separating punctuation.

5.1.6 Grammar Notation

Terminal symbols of the lexical, RegExp, and numeric string grammars, and some of the terminal symbols of the other grammars, are shown in fixed width font, both in the productions of the grammars and throughout this specification whenever the text directly refers to such a terminal symbol. These are to appear in a script either exactly as written or using equivalent Unicode escape sequences (see clause 10). All terminal character symbols specified in this way are to be understood as the appropriate Unicode character from the ASCII range, as opposed to any similar-looking characters from other Unicode ranges.

Nonterminal symbols are shown in italic type. The definition of a nonterminal (also called a "production") is introduced by the name of the nonterminal being defined followed by one or more colons. (The number of colons indicates to which grammar the production belongs.) One or more alternative right-hand sides for the nonterminal then follow on succeeding lines. For example, the syntactic definition:

```
WhileStatement::
  while ( Expression ) Statement
```

states that the nonterminal WhileStatement represents the token while, followed by a left parenthesis token, followed by an Expression, followed by a right parenthesis token, followed by a Statement. The occurrences of Expression and Statement are themselves nonterminals. As another example, the syntactic definition:
states that an ArgumentList may represent either a single AssignmentExpression or an ArgumentList, followed by
a comma, followed by an AssignmentExpression. This definition of ArgumentList is recursive, that is, it is defined
in terms of itself. The result is that an ArgumentList may contain any positive number of arguments, separated
by commas, where each argument expression is an AssignmentExpression. Such recursive definitions of
nonterminals are common.

The subscripted suffix "opt", which may appear after a terminal or nonterminal, indicates an optional symbol.
The alternative containing the optional symbol actually specifies two right-hand sides, one that omits the
optional element and one that includes it. This means that:

VariableDeclaration : Identifier Initialiser opt

is a convenient abbreviation for:

VariableDeclaration : Identifier

and that:

IterationStatement :
    for ( Expression opt ; Expression opt ; Expression opt ) Statement

is a convenient abbreviation for:

IterationStatement :
    for ( Expression ; Expression opt ; Expression opt ) Statement
    for ( ; Expression opt ; Expression opt ) Statement

which in turn is an abbreviation for:

IterationStatement :
    for ( ; ; ) Statement
    for ( ; ; Expression ) Statement
    for ( ; Expression ; ; ) Statement
    for ( ; Expression ; Expression ) Statement
    for ( Expression ; ; ) Statement
    for ( Expression ; Expression ; ) Statement

which in turn is an abbreviation for:

IterationStatement :
    for ( ; ; ) Statement
    for ( ; ; Expression ) Statement
    for ( ; Expression ; ; ) Statement
    for ( ; Expression ; Expression ) Statement
    for ( Expression ; ; ) Statement
    for ( Expression ; Expression ; ) Statement

so the nonterminal IterationStatement actually has eight alternative right-hand sides.

When the words "one of" follow the colon(s) in a grammar definition, they signify that each of the terminal
symbols on the following line or lines is an alternative definition. For example, the lexical grammar for
ECMAScript contains the production:
NonZeroDigit :: one of
  1  2  3  4  5  6  7  8  9

which is merely a convenient abbreviation for:

NonZeroDigit ::
  1
  2
  3
  4
  5
  6
  7
  8
  9

If the phrase "[empty]" appears as the right-hand side of a production, it indicates that the production’s right-hand side contains no terminals or nonterminals.

If the phrase "[lookahead ∈ set]" appears in the right-hand side of a production, it indicates that the production may not be used if the immediately following input token is a member of the given set. The set can be written as a list of terminals enclosed in curly braces. For convenience, the set can also be written as a nonterminal, in which case it represents the set of all terminals to which that nonterminal could expand. For example, given the definitions

DecimalDigit :: one of
  0  1  2  3  4  5  6  7  8  9

DecimalDigits ::
  DecimalDigit
  DecimalDigits DecimalDigit

the definition

LookaheadExample ::
  n [lookahead ∈ {1, 3, 5, 7, 9}] DecimalDigits
  DecimalDigit [lookahead ∈ DecimalDigit]

matches either the letter n followed by one or more decimal digits the first of which is even, or a decimal digit not followed by another decimal digit.

If the phrase "[no LineTerminator here]" appears in the right-hand side of a production of the syntactic grammar, it indicates that the production is a restricted production: it may not be used if a LineTerminator occurs in the input stream at the indicated position. For example, the production:

ThrowStatement ::
  throw [no LineTerminator here] Expression ;

indicates that the production may not be used if a LineTerminator occurs in the script between the throw token and the Expression.

Unless the presence of a LineTerminator is forbidden by a restricted production, any number of occurrences of LineTerminator may appear between any two consecutive tokens in the stream of input elements without affecting the syntactic acceptability of the script.

The lexical grammar has multiple goal symbols and the appropriate goal symbol to use depends upon the syntactic grammar context. If a phrase of the form "[lexical goal LexicalGoalSymbol]" appears on the right-hand-side of a syntactic production then the next token must be lexically recognised using the indicated goal symbol. In the absence of such a phrase the default lexical goal symbol is used.
When an alternative in a production of the lexical grammar or the numeric string grammar appears to be a multi-character token, it represents the sequence of characters that would make up such a token.

The right-hand side of a production may specify that certain expansions are not permitted by using the phrase "but not" and then indicating the expansions to be excluded. For example, the production:

```
Identifier ::
  IdentifierName but not ReservedWord
```

means that the nonterminal `Identifier` may be replaced by any sequence of characters that could replace `IdentifierName` provided that the same sequence of characters could not replace `ReservedWord`.

Finally, a few nonterminal symbols are described by a descriptive phrase in sans-serif type in cases where it would be impractical to list all the alternatives:

```
SourceCharacter ::
  any Unicode character
```

5.2 Algorithm Conventions

The specification often uses a numbered list to specify steps in an algorithm. These algorithms are used to precisely specify the required semantics of ECMAScript language constructs. The algorithms are not intended to imply the use of any specific implementation technique. In practice, there may be more efficient algorithms available to implement a given feature.

Algorithms may be explicitly parameterised, in which case the names and usage of the parameters must be provided as part of the algorithm's definition. In order to facilitate their use in multiple parts of this specification, some algorithms, called abstract operations, are named and written in parameterised functional form so that they may be referenced by name from within other algorithms.

Algorithms may be associated with productions of one of the ECMAScript grammars. A production that has multiple alternative definitions will typically have a distinct algorithm for each alternative. When an algorithm is associated with a grammar production, it may reference the terminal and non-terminal symbols of the production alternative as if they were parameters of the algorithm. When used in this manner, non-terminal symbols refer to the actual alternative definition that is matched when parsing the script source code.

Unless explicitly specified otherwise, all chain productions have an implicit associated definition for every algorithm that is might be applied to that production's left-hand side nonterminal. The implicit simply reapplies the same algorithm name with the same parameters, if any, to the chain production's sole right-hand side nonterminal and then result. For example, assume there is a production

```
Block : { StatementList }
```

but there is no evaluation algorithm that is explicitly specified for that production. If in some algorithm there is a statement of the form: "Return the result of evaluating Block" it is implicit that the algorithm has an evaluation algorithm of the form:

```
Runtime Semantics: Evaluation

Block : { StatementList }
```

1. Return the result of evaluating `StatementList`

For clarity of expression, algorithm steps may be subdivided into sequential substeps. Substeps are indented and may themselves be further divided into indented substeps. Outline numbering conventions are used to identify substeps with the first level of substeps labelled with lower case alphabetic characters and the second level of substeps labelled with lower case roman numerals. If more than three levels are required these rules repeat with the fourth level using numeric labels. For example:
1. Top-level step
   a. Substep.
   b. Substep.
      i. Subsubstep.
      ii. Subsubstep.

A step or substep may be written as an "if" predicate that conditions its substeps. In this case, the substeps are only applied if the predicate is true. If a step or substep begins with the word "else", it is a predicate that is the negation of the preceding "if" predicate step at the same level.

A step may specify the iterative application of its substeps.

A step may assert an invariant condition of its algorithm. Such assertions are used to make explicit algorithmic invariants that would otherwise be implicit. Such assertions add no additional semantic requirements and hence need not be checked by an implementation. They are used simply to clarify algorithms.

Mathematical operations such as addition, subtraction, negation, multiplication, division, and the mathematical functions defined later in this clause should always be understood as computing exact mathematical results on mathematical real numbers, which do not include infinities and do not include a negative zero that is distinguished from positive zero. Algorithms in this standard that model floating-point arithmetic include explicit steps, where necessary, to handle infinities and signed zero and to perform rounding. If a mathematical operation or function is applied to a floating-point number, it should be understood as being applied to the exact mathematical value represented by that floating-point number; such a floating-point number must be finite, and if it is +0 or −0 then the corresponding mathematical value is simply 0.

The mathematical function abs(x) produces the absolute value of x, which is −x if x is negative (less than zero) and otherwise is x itself.

The mathematical function sign(x) produces 1 if x is positive and −1 if x is negative. The sign function is not used in this standard for cases when x is zero.

The mathematical function min(x1, x2, ..., xn) produces the mathematically smallest of x1 through xn.

The notation "x modulo y" (y must be finite and nonzero) computes a value k of the same sign as y (or zero) such that abs(k) < abs(y) and x-k = y * q for some integer q.

The mathematical function floor(x) produces the largest integer (closest to positive infinity) that is not larger than x.

NOTE floor(x) = x-(x modulo 1).

### 5.3 Static Semantic Rules

Context-free grammars are not sufficiently powerful to express all the rules that define whether a stream of input elements make up a valid ECMAScript script that may be evaluated. In some situations additional rules are needed that may be expressed using either ECMAScript algorithm conventions or prose requirements. Such rules are always associated with a production of a grammar and are called the static semantics of the production.

Static Semantic Rules have names and typically are defined using an algorithm. Named Static Semantic Rules are associated with grammar productions and a production that has multiple alternative definitions will typically have for each alternative a distinct algorithm for each applicable named static semantic rule.
Unless otherwise specified every grammar production alternative in this specification implicitly has a definition for a static semantic rule named Contains which takes an argument named symbol whose value is a terminal or non-terminal of the grammar that includes the associated production. The default definition of Contains is:

1. For each terminal and non-terminal grammar symbol, sym, in the definition of this production do
   a. If sym is the same grammar symbol as symbol, return true.
   b. If sym is a non-terminal, then
      i. Let contained be the result of Contains for sym with argument symbol.
      ii. If contained is true, return true.
2. Return false.

The above definition is explicitly over-ridden for specific productions.

A special kind of static semantic rule is an Early Error Rule. Early error rules define early error conditions (see clause 16) that are associate with specific grammar productions. Evaluation of most early error rules are not explicitly invoked within the algorithms of this specification. A conforming implementation must, prior to the first evaluation of a Script, validate all of the early error rules of the productions used to parse that Script. If any of the early error rules are violated the Script is invalid and cannot be evaluated.

6 ECMAScript Data Types and Values

Algorithms within this specification manipulate values each of which has an associated type. The possible value types are exactly those defined in this clause. Types are further subclassified into ECMAScript language types and specification types.

Within this specification, the notation "Type(x)" is used as shorthand for "the type of x" where "type" refers to the ECMAScript language and specification types defined in this clause.

6.1 ECMAScript Language Types

An ECMAScript language type corresponds to values that are directly manipulated by an ECMAScript programmer using the ECMAScript language. The ECMAScript language types are Undefined, Null, Boolean, String, Number, and Object. An ECMAScript language value is a value that is characterized by an ECMAScript language type.

6.1.1 The Undefined Type

The Undefined type has exactly one value, called undefined. Any variable that has not been assigned a value has the value undefined.

6.1.2 The Null Type

The Null type has exactly one value, called null.

6.1.3 The Boolean Type

The Boolean type represents a logical entity having two values, called true and false.

6.1.4 The String Type

The String type is the set of all finite ordered sequences of zero or more 16-bit unsigned integer values ("elements"). The String type is generally used to represent textual data in a running ECMAScript program, in which case each element in the String is treated as a UTF-16 code unit value. Each element is regarded as occupying a position within the sequence. These positions are indexed with nonnegative integers. The first element (if any) is at index 0, the next element (if any) at index 1, and so on. The length of a String is the number of elements (i.e., 16-bit values) within it. The empty String has length zero and therefore contains no elements.
Where ECMAScript operations interpret String values, each element is interpreted as a single UTF-16 code unit. However, ECMAScript does not place any restrictions or requirements on the sequence of code units in a String value, so they may be ill-formed when interpreted as UTF-16 code unit sequences. Operations that do not interpret String contents treat them as sequences of undifferentiated 16-bit unsigned integers. No operations ensure that Strings are in a normalized form. Only operations that are explicitly specified to be language or locale sensitive produce language-sensitive results.

NOTE The rationale behind this design was to keep the implementation of Strings as simple and high-performing as possible. If ECMAScript source code is in Normalised Form C, string literals are guaranteed to also be normalised, as long as they do not contain any Unicode escape sequences.

Some operations interpret String contents as UTF-16 encoded Unicode code points. In that case the interpretation is:

- A code unit in the range 0 to 0x10FFFF is interpreted as a code point with the same value.
- A sequence of two code units, where the first code unit \( c_1 \) is in the range 0xD800 to 0xDBFF and the second code unit \( c_2 \) is in the range 0xDC00 to 0xDFFF, is a surrogate pair and is interpreted as a code point with the value \( (c_1 \times 0x10000 + c_2) \times 0x10000 + 0x10000 \).
- A code unit that is in the range 0xD800 to 0xDFFF, but is not part of a surrogate pair, is interpreted as a code point with the same value.

### 6.1.5 The Number Type

The Number type has exactly \( \mathcal{2}^{53} - 2^{52} \) values, representing the double-precision 64-bit format IEEE 754 values as specified in the IEEE Standard for Binary Floating-Point Arithmetic, except that the 9007199254740990 (that is, \( 2^{53} \)) distinct “Not-a-Number” values of the IEEE Standard are represented in ECMAScript as a single special NaN value. (Note that the NaN value is produced by the program expression NaN. In some implementations, external code might be able to detect a difference between various NaN values, but such behaviour is implementation-dependent; to ECMAScript code, all NaN values are indistinguishable from each other.

There are two other special values, called **positive infinity** and **negative infinity**. For brevity, these values are also referred to for expository purposes by the symbols \( +\infty \) and \( -\infty \), respectively. (Note that these two infinite Number values are produced by the program expressions \( +\infty \) (or simply \( \infty \)) and \( -\infty \).)

The other \( \mathcal{2}^{53} - 2^{52} \) values are called the finite numbers. Half of these are positive numbers and half are negative numbers; for every finite positive Number value there is a corresponding negative value having the same magnitude.

Note that there is both a **positive zero** and a **negative zero**. For brevity, these values are also referred to for expository purposes by the symbols \( 0 \) and \( -0 \), respectively. (Note that these two different zero Number values are produced by the program expressions \( 0 \) (or simply \( 0 \)) and \( -0 \).)

The 18437736874454810622 (that is, \( 2^{54} - 2^{53} - 2 \)) finite nonzero values are of two kinds:

- The 18428729675200069632 (that is, \( 2^{54} - 2^{53} \)) of them are normalised, having the form \( s \times m \times 2^e \) where \( s = +1 \) or \( -1 \), \( m \) is a positive integer less than \( 2^{53} \) but not less than \( 2^{52} \), and \( e \) is an integer ranging from \(-1074\) to \(971\), inclusive.

- The remaining 9007199254740990 (that is, \( 2^{53} - 2 \)) values are denormalised, having the form \( s \times m \times 2^e \) where \( s = +1 \) or \( -1 \), \( m \) is a positive integer less than \( 2^{53} \), and \( e \) is \(-1074\).
Note that all the positive and negative integers whose magnitude is no greater than $2^{31}$ are representable in the Number type (indeed, the integer 0 has two representations, +0 and −0).

A finite number has an odd significand if it is nonzero and the integer $m$ used to express it (in one of the two forms shown above) is odd. Otherwise, it has an even significand.

In this specification, the phrase “the Number value for $x$” where $x$ represents an exact nonzero real mathematical quantity (which might even be an irrational number such as $\pi$) means a Number value chosen in the following manner. Consider the set of all finite values of the Number type, with −0 removed and with two additional values added to it that are not representable in the Number type, namely $2^{1024}$ (which is $+1 \times 2^{971}$) and $−2^{1024}$ (which is $−1 \times 2^{971}$). Choose the member of this set that is closest in value to $x$. If two values of the set are equally close, then the one with an even significand is chosen; for this purpose, the two extra values $2^{1024}$ and $−2^{1024}$ are considered to have even significands. Finally, if $2^{1024}$ was chosen, replace it with $+\infty$; if $−2^{1024}$ was chosen, replace it with $−\infty$; if +0 was chosen, replace it with +0 if and only if $x$ is less than zero; any other chosen value is used unchanged. The result is the Number value for $x$. (This procedure corresponds exactly to the behaviour of the IEEE 754 “round to nearest” mode.)

Some ECMAScript operators deal only with integers in the range $−2^{31}$ through $2^{31}−1$, inclusive, or in the range 0 through $2^{32}−1$, inclusive. These operators accept any value of the Number type but first convert each such value to one of $2^{32}$ integer values. See the descriptions of the ToInt32 and ToUint32 operators in 7.1.5 and 7.1.6, respectively.

6.1.6 The Object Type

An Object is logically a collection of properties. Each property is either a data property, or an accessor property:

- A data property associates a key value with an ECMAScript language value and a set of Boolean attributes.
- A accessor property associates a key value with one or two accessor functions, and a set of Boolean attributes. The accessor functions are used to store or retrieve an ECMAScript language value that is associated with the property.

Properties are identified using key values. A key value is either an ECMAScript String value or an Exotic Symbol object.

Property keys are used to access properties and their values. There are two kinds of access for properties: get and set, corresponding to value retrieval and assignment, respectively. The properties accessible via get and set access includes both own properties that are a direct part of an object and inherited properties which are provided by another associated object via a property inheritance relationship. Inherited properties may be either own or inherited properties of the associated object.

All objects are logically collections of properties, but there are multiple forms of objects that differ in their semantics for accessing and manipulating their properties. Ordinary objects are the most common form of objects and have the default object semantics. An exotic object is any form of object whose property semantics differ in any way from the default semantics.

6.1.6.1 Property Attributes

Attributes are used in this specification to define and explain the state of Object properties. A data property associates a key value with the attributes listed in Table 1.
Table 1 — Attributes of a Data Property

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Value Domain</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Value]]</td>
<td>Any ECMAScript language type</td>
<td>The value retrieved by a get access of the property.</td>
</tr>
<tr>
<td>[[Writable]]</td>
<td>Boolean</td>
<td>If false, attempts by ECMAScript code to change the property's [[Value]] attribute using [[Set]] will not succeed.</td>
</tr>
<tr>
<td>[[Enumerable]]</td>
<td>Boolean</td>
<td>If true, the property will be enumerated by a for-in enumeration (see 13.6.4). Otherwise, the property is said to be non-enumerable.</td>
</tr>
<tr>
<td>[[Configurable]]</td>
<td>Boolean</td>
<td>If false, attempts to delete the property, change the property to be an accessor property, or change its attributes (other than [[Value]], or changing [[Writable]] to false) will fail.</td>
</tr>
</tbody>
</table>

An accessor property associates a key value with the attributes listed in Table 2.

Table 2 — Attributes of an Accessor Property

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Value Domain</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Get]]</td>
<td>Object or Undefined</td>
<td>If the value is an Object it must be a function Object. The function's [[Call]] internal method (Table 5) is called with an empty arguments list to retrieve the property value each time a get access of the property is performed.</td>
</tr>
<tr>
<td>[[Set]]</td>
<td>Object or Undefined</td>
<td>If the value is an Object it must be a function Object. The function's [[Call]] internal method (Table 5) is called with an arguments list containing the assigned value as its sole argument each time a set access of the property is performed. The effect of a property's [[Set]] internal method may, but is not required to, have an effect on the value returned by subsequent calls to the property's [[Get]] internal method.</td>
</tr>
<tr>
<td>[[Enumerable]]</td>
<td>Boolean</td>
<td>If true, the property is to be enumerated by a for-in enumeration (see 13.6.4). Otherwise, the property is said to be non-enumerable.</td>
</tr>
<tr>
<td>[[Configurable]]</td>
<td>Boolean</td>
<td>If false, attempts to delete the property, change the property to be a data property, or change its attributes will fail.</td>
</tr>
</tbody>
</table>

If the initial values of a property's attributes are not explicitly specified by this specification, the default value defined in Table 3 is used.

Table 3 — Default Attribute Values

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Value]]</td>
<td>undefined</td>
</tr>
<tr>
<td>[[Get]]</td>
<td>undefined</td>
</tr>
<tr>
<td>[[Set]]</td>
<td>undefined</td>
</tr>
<tr>
<td>[[Writable]]</td>
<td>false</td>
</tr>
<tr>
<td>[[Enumerable]]</td>
<td>false</td>
</tr>
<tr>
<td>[[Configurable]]</td>
<td>false</td>
</tr>
</tbody>
</table>

6.1.6.2 Object Internal Methods and Internal Data Properties

The actual semantics of ECMAScript objects are specified via algorithms called internal methods. Each object in an ECMAScript engine is associated with a set of internal methods that defines its runtime behaviour.
These internal methods are not part of the ECMAScript language. They are defined by this specification purely for expository purposes. However, each object within an implementation of ECMAScript must behave as specified by the internal methods associated with it. The exact manner in which this is accomplished is determined by the implementation.

Internal methods are identified within this specification using names enclosed in double square brackets `[[ ]]`. Internal method names are polymorphic. This means that different ECMAScript object values may perform different algorithms when a common internal method name is invoked upon them. If, at runtime, the implementation of an algorithm attempts to use an internal method of an object that the object does not support, a `TypeError` exception is thrown.

Internal data properties correspond to internal state that is associated with objects and used by various ECMAScript specification algorithms. Depending upon the specific internal data property such state may consist of values of any ECMAScript language type or of specific ECMA specification type values. Unless explicitly specified otherwise, internal data properties are allocated as part of the process of creating an ECMAScript object and may not be dynamically added to ECMAScript objects. Unless specified otherwise, the initial value of an internal data property is the value `undefined`.

Table 4 summarises the essential internal methods used by this specification that are applicable to all ECMAScript objects. Every object must have algorithms for all of the essential internal methods. However, all objects do not necessarily use the same algorithms for those methods.

The “Signature” column of Table 4 and other similar tables describes the invocation pattern for each internal method. The invocation pattern always includes a parenthesised list of descriptive parameter names. If a parameter name is the same as an ECMAScript type name then the name describes the required type of the parameter value. If an internal method explicitly returns a value, its parameter list is followed by the symbol “→” and the type name of the returned value. The type names used in signatures refer to the types defined in Clause 6 augmented by the following additional names: “any” means the value may be any ECMAScript language type. An internal method implicitly returns a Completion Record as described in 6.2.3. In addition to its parameters, an internal method always has access to the object upon which it is invoked as a method.
Table 4 — Essential Internal Methods

<table>
<thead>
<tr>
<th>Internal Method</th>
<th>Signature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
[GetInheritance]        | () → Object or Null        | Determine the object that provides inherited properties for this object. A null value indicates that there are no inherited properties.          |
| [SetInheritance]        | (Object or Null) → Boolean | Associate with an object another object that provides inherited properties. Passing null indicates that there are no inherited properties. Returns true indicating that the operation was completed successfully or false indicating that the operation was not successful. |
| [isExtensible]          | () → Boolean               | Determine whether it is permitted to add additional properties to an object.                                                                  |
| [PreventExtensions]     | () → Boolean               | Control whether new properties may be added to an object. Returns true indicating that the operation was completed successfully or false indicating that the operation was not successful. |
| [HasOwnProperty]        | (propertyKey) → Boolean    | Returns a Boolean value indicating whether the object already has an own property whose key is propertyKey.                                     |
| [GetProperty]           | (propertyKey) → PropertyDescriptor | Returns a Property Descriptor for the own property of this object whose key is propertyKey or undefined if no such property exists.             |
| [DefineOwnProperty]     | (propertyKey, PropertyDescriptor) → Boolean | Creates or alters the named own property to have the state described by a Property Descriptor. Returns true indicating that the property was successfully created/updated or false indicating that the property could not be created or updated. |
| [Enumerate]             | () → Object                | Returns an iterator object over the string values of the keys of the enumerable properties of the object.                                    |

Table 5 summarises additional essential internal methods that are supported by objects that may be called as functions.
Table 5 — Additional Essential Internal Methods of Function Objects

<table>
<thead>
<tr>
<th>Internal Method</th>
<th>Signature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Call]]</td>
<td>(any, a List of any) → any</td>
<td>Executes code associated with the object. Invoked via a function call expression. The arguments to the internal method are a <code>this</code> value and a list containing the arguments passed to the function by a call expression. Objects that implement this internal method are callable.</td>
</tr>
<tr>
<td>[[Construct]]</td>
<td>(a List of any) → Object</td>
<td>Creates an object. Invoked via the <code>new</code> operator. The arguments to the internal method are the arguments passed to the <code>new</code> operator. Objects that implement this internal method are called constructors. A Function object is not necessarily a constructor and such non-constructor Function objects do not have a [[Construct]] internal method.</td>
</tr>
</tbody>
</table>

6.1.6.3 Invariants of the Essential Internal Methods

Current this section is just a bunch of material merged together from the ES5 spec. and from the wiki Proxy pages. It need to be completely reworked.

The intent is that it lists all invariants of the Essential Internal Methods. This includes both invariants that are enforced for Proxy objects and other invariants that may not be enforced.

Definitions:

- The target of an internal method is the object the internal method is called upon.
- A sealed property is a non-configurable own property of a target.
- A frozen property is a non-configurable non-writable own property of a target.
- A new property is a property that does not exist on a non-extensible target.
- Two property descriptors `desc1` and `desc2` for a property `key` value are incompatible if:
  1. `desc1` is produced by calling `[[GetOwnPropertyDescriptor]] of target with key, and`
  2. Calling `[[DefineOwnProperty]] of target with arguments key and desc2` would throw a `TypeError` exception.

Exotic objects may define additional constraints upon their `[[Set]]` internal method behaviour. If possible, exotic objects should not allow `[[Set]]` operations in situations where this definition of `[[CanPut]]` returns `false`.

`[[GetInheritance]]`

Every `[[Prototype]]` chain must have finite length (that is, starting from any object, recursively accessing the `[[Prototype]]` internal data property must eventually lead to a `null` value).

`getOwnPropertyDescriptor`

Non-configurability invariant: cannot return incompatible descriptors for sealed properties.
Non-extensibility invariant: must return `undefined` for new properties.
Invariant checks:
- if trap returns `undefined`, check if the property is configurable
- if property exists on target, check if the returned descriptor is compatible
- if returned descriptor is non-configurable, check if the property exists on the target and is also non-configurable
defineProperty

Non-configurability invariant: cannot succeed (return true) for incompatible changes to sealed properties.

Non-extensibility invariant: must reject (return false) for new properties.

Invariant checks:
- on success, if property exists on target, check if existing descriptor is compatible with argument descriptor.
- on success, if argument descriptor is non-configurable, check if the property exists on the target and is also non-configurable.

getOwnPropertyNames

Non-configurability invariant: must report all sealed properties.

Non-extensibility invariant: must not list new property names.

Invariant checks:
- check whether all sealed target properties are present in the trap result.
- If the target is non-extensible, check that no new properties are listed in the trap result.

deleteProperty

Non-configurability invariant: cannot succeed (return true) for sealed properties.

Invariant checks:
- on success, check if the target property is configurable.

getPrototypeOf

Invariant check: check whether the target’s prototype and the trap result are identical (according to the egal operator).

freeze | seal | preventExtensions

Invariant checks:
- on success, check if isFrozen(target), isSealed(target) or isExtensible(target).

isFrozen | isSealed | isExtensible

Invariant check: check whether the boolean trap result is equal to isFrozen(target), isSealed(target) or isExtensible(target).

hasOwnProperty

Non-configurability invariant: cannot return false for sealed properties.

Non-extensibility invariant: must return false for new properties.

Invariant checks:
- if false is returned, check if the target property is configurable.

has

Non-configurability invariant: cannot return false for sealed properties.

Invariant checks:
- if false is returned, check if the target property is configurable.
get

Non-configurability invariant: cannot return inconsistent values for frozen data properties, and must return `undefined` for sealed accessors with an `undefined` getter.

Invariant checks:

- If property exists on target as a data property, check whether the target property's value and the trap result are identical (according to the egal operator).
- If property exists on target as an accessor, and the accessor's get attribute is `undefined`, check whether the trap result is also `undefined`.

set

Non-configurability invariant: cannot succeed (return true) for frozen data properties or sealed accessors with an `undefined` setter.

Invariant checks:

- On success, if property exists on target as a data property, check whether the target property's value and the update value are identical (according to the egal operator).
- On success, if property exists on target as an accessor, check whether the accessor's set attribute is not `undefined`.

keys

Non-configurability invariant: must report all enumerable sealed properties

Non-extensibility invariant: must not list new property names.

Invariant checks:

- Check whether all enumerable sealed target properties are listed in the trap result.
- If the target is non-extensible, check that no new properties are listed in the trap result.

enumerate

Non-configurability invariant: must report all enumerable sealed properties.

Invariant checks:

- Check whether all enumerable sealed target properties are listed in the trap result.

NOTE: This specification defines no ECMAScript language operators or built-in functions that permit a program to modify an object's `[[Prototype]]` internal properties or to change the value of `[[Extensible]]` from false to true. Implementation specific extensions that modify `[[Prototype]]` or `[[Extensible]]` must not violate the invariants defined in the preceding paragraphs.

Unless otherwise specified, the standard ECMAScript objects are ordinary objects and behave as described in 9.1. Some standard objects are exotic objects and have behaviour defined in 9.2.

Exotic objects may implement internal methods in any manner unless specified otherwise; for example, one possibility is that `[[Get]]` and `[[Set]]` for a particular exotic object indeed fetch and store property values but `[[HasOwnProperty]]` always generates `false`. However, if any specified manipulation of an exotic object's internal properties is not supported by an implementation, that manipulation must throw a `TypeError` exception when attempted.

The `[[GetOwnProperty]]` internal method of all objects must conform to the following invariants for each property of the object:
If a property is described as a data property and it may return different values over time, then either or both of the [[Writable]] and [[Configurable]] attributes must be `true` even if no mechanism to change the value is exposed via the other internal methods.

If a property is described as a data property and its [[Writable]] and [[Configurable]] are both `false`, then the SameValue (according to 7.2.3) must be returned for the [[Value]] attribute of the property on all calls to [[GetOwnProperty]].

If the attributes other than [[Writable]] may change over time or if the property might disappear, then the [[Configurable]] attribute must be `true`.

If the [[Writable]] attribute may change from `false` to `true`, then the [[Configurable]] attribute must be `true`.

If the result of calling an object’s [[IsExtensible]] internal method has been observed by ECMAScript code to be `false`, then if a call to [[GetOwnProperty]] describes a property as non-existent all subsequent calls must also describe that property as non-existent.

The [[DefineOwnProperty]] internal method of all objects must not permit the addition of a new property to an object if the [[Extensible]] internal method of that object has been observed by ECMAScript code to be `false`.

If the result of calling the [[IsExtensible]] internal method of an object has been observed by ECMAScript code to be `false` then it must not subsequently become `true`.

### 6.1.6.4 Well-Known Symbols and Intrinsics

Well-known symbols are built-in Symbol exotic objects (9.2.4) that are explicitly referenced by algorithms of this specification. They are typically used as the keys of properties whose values serve as extension points of a specification algorithm. Unless otherwise specified, well-known symbols objects are shared by all Code Realms (8.2).

Within this specification a well-known symbol is referred to by using a notation of the form `@@name`, where “name” is one of the values listed in Table 6.

#### Table 6 — Well-known Symbols

<td>A string value that is used in the creation of the default string description of an object. Called by the built-in method Object.prototype.toString.</td>
</tr>
<tr>
<td>@@unscopables</td>
<td>An Array of strings values that are property names that are excluded from the with environment bindings of the associated objects.</td>
</tr>
</tbody>
</table>
Well-known intrinsics are built-in objects that are explicitly referenced by the algorithms of this specification and which usually have Realm specific identities. Unless otherwise specified each intrinsic object actually corresponds to a set of similar objects, one per Realm.

Within this specification a reference such as %name% means the intrinsic object, associated with the current Realm, corresponding to the name. Determination of the current Realm and its intrinsics is described in 8.2. The well-known intrinsics are listed in Table 7.

6.2 ECMAScript Specification Types

A specification type corresponds to meta-values that are used within algorithms to describe the semantics of ECMAScript language constructs and ECMAScript language types. The specification types are Reference, List, Completion, Property Descriptor, Lexical Environment, Environment Record, and Data Block. Specification type values are specification artefacts that do not necessarily correspond to any specific entity within an ECMAScript implementation. Specification type values may be used to describe intermediate results of ECMAScript expression evaluation but such values cannot be stored as properties of objects or values of ECMAScript language variables.

6.2.1 Data Blocks

This section is a placeholder for describing the Data Block internal type. The following material is verbatim from the Binary Data ES wiki proposal. The material has not yet been reviewed or integrated with the rest of this spec.

This spec introduces a new, spec-internal block datatype, intuitively representing a contiguously allocated block of binary data. Blocks are not ECMAScript language values and appear only in the program store (aka heap).

A block is one of:
- a number-block
- an array-block[t, n]
- a struct-block[t1, ..., tn]

A number-block is one of:
- an unsigned-integer; i.e., one of uint8, uint16, uint32, or uint64
- a signed-integer; i.e., one of int8, int16, int32, or int64
- a floating-point; i.e., one of float32 or float64

A uintk is an integer in the range [0, 2^k). An intk is an integer in the range [-2^k-1, 2^k-1). A floatk is a floating-point number representable as a k-bit IEEE754 value.

An array-block[t, n] is an ordered sequence of n blocks of homogeneous block type t. Each element of the array is stored at an independently addressable location in the program store, and multiple Data objects may contain references to the element.

A struct-block[t1, ..., tn] is an ordered sequence of n blocks of heterogeneous types t1 to tn, respectively. Each field of the struct is stored at an independently addressable location in the program store, and multiple Data objects may contain references to the field.

The spec also introduces a datatype of Data objects, which are ECMAScript objects that encapsulate references to block data in the program store. Every Data object has the following properties:

- [[Class]] = “Data”
- [[Value]] : reference[block] – a reference to a block in the program store
- [[DataType]] : reference[Type] – a reference to a Type object describing this object’s data block

6.2.2 The List and Record Specification Type

The List type is used to explain the evaluation of argument lists (see 12.2.5) in new expressions, in function calls, and in other algorithms where a simple list of values is needed. Values of the List type are simply ordered sequences of values. These sequences may be of any length.
The Record type is used to describe data aggregations within the algorithms of this specification. A Record type value consists of one or more named fields. The value of each field is either an ECMAScript value or an abstract value represented by a name associated with the Record type. Field names are always enclosed in double brackets, for example `[[value]]`.

For notational convenience within this specification, an object literal-like syntax can be used to express a Record value. For example, `[[field1]]: 42, [[field2]]: false, [[field3]]: empty` defines a Record value that has three fields each of which is initialised to a specific value. Field name order is not significant. Any fields that are not explicitly listed are considered to be absent.

In specification text and algorithms, dot notation may be used to refer to a specific field of a Record value. For example, if `R` is the record shown in the previous paragraph then `R.[[field2]]` is shorthand for "the field of `R` named `[[field2]]`".

Schema for commonly used Record field combinations may be named, and that name may be used as a prefix to a literal Record value to identify the specific kind of aggregations that is being described. For example: `Property Descriptor `[[Value]]`: 42, `[[Writable]]`: false, `[[Configurable]]`: true`.

### 6.2.3 The Completion Record Specification Type

The Completion type is a Record used to explain the runtime propagation of values and control flow such as the behaviour of statements (break, continue, return and throw) that perform nonlocal transfers of control.

Values of the Completion type are Record values whose fields are defined as by Table 8.

**Table 8 — Completion Record Fields**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[[type]]</code></td>
<td>One of normal, break, continue, return, or throw</td>
<td>The type of completion that occurred.</td>
</tr>
<tr>
<td><code>[[value]]</code></td>
<td>any ECMAScript language value or empty</td>
<td>The value that was produced.</td>
</tr>
<tr>
<td><code>[[target]]</code></td>
<td>any ECMAScript identifier or empty</td>
<td>The target label for directed control transfers.</td>
</tr>
</tbody>
</table>

The term "abrupt completion" refers to any completion with a `[[type]]` value other than normal.

#### 6.2.3.1 NormalCompletion

The abstract operation NormalCompletion with a single argument, such as:

1. `Return NormalCompletion(argument)`.

Is a short hand that is defined as follows:

1. `Return Completion `[[type]]`: normal, `[[value]]`: argument, `[[target]]`: empty`.

#### 6.2.3.2 Implicit Completion Values

The algorithms of this specification often implicitly return Completion Records whose `[[type]]` is normal. Unless it is otherwise obvious from the context, an algorithm statement that returns a value that is not a Completion Record, such as:

1. `Return "Infinity"`.

Generally means the same thing as:

1. `Return NormalCompletion("Infinity")`. 
A "return" statement without a value in an algorithm step means the same thing as:

1. Return NormalCompletion(undefi ned).

Similarly, any reference to a Completion Record value that is in a context that does not explicitly require a complete Completion Record value is equivalent to an explicit reference to the [[value]] field of the Completion Record value unless the Completion Record is an abrupt completion.

### 6.2.3.3 Throw an Exception

Algorithms steps that say to throw an exception, such as

1. Throw a TypeError exception.

Mean the same things as:

1. Return Completion (type: throw, value: a newly created TypeError object, target: empty).

### 6.2.3.4 ReturnIfAbrupt

Algorithms steps that say

1. ReturnIfAbrupt(argument).

mean the same things as:

1. If argument is an abrupt completion, then return argument.
2. Else if argument is a Completion Record, then let argument be argument.[[value]].

### 6.2.4 The Reference Specification Type

**NOTE** The Reference type is used to explain the behaviour of such operators as delete, typeof, the assignment operators, the super keyword and other language features. For example, the left-hand operand of an assignment is expected to produce a reference.

A **Reference** is a resolved name or property binding. A Reference consists of three components, the base value, the referenced name and the Boolean valued strict reference flag. The base value is either undefined, an Object, a Boolean, a String, a Number, or an environment record (8.1.1). A base value of undefined indicates that the Reference could not be resolved to a binding. The referenced name is a String or Symbol.

A **Super Reference** is a Reference that is used to represents a name binding that was expressed using the super keyword. A Super Reference has an additional thisValue component and its base value will never be an environment record.

The following abstract operations are used in this specification to access the components of references:

- GetBase(V). Returns the base value component of the reference V.
- GetReferencedName(V). Returns the referenced name component of the reference V.
- IsStrictReference(V). Returns the strict reference flag component of the reference V.
- HasPrimitiveBase(V). Returns true if the base value is a Boolean, String, or Number.
- IsPropertyReference(V). Returns true if either the base value is an object or HasPrimitiveBase(V) is true; otherwise returns false.
- IsUnresolvableReference(V). Returns true if the base value is undefined and false otherwise.
- IsSuperReference(V). Returns true if this reference has a thisValue component.

The following abstract operations are used in this specification to operate on references:
6.2.4.1 GetValue (V)

1. ReturnIfAbrupt(V).
2. If Type(V) is not Reference, return V.
3. Let base be the result of calling GetBase(V).
4. If IsUnresolvableReference(V), throw a ReferenceError exception.
5. If IsPropertyReference(V), then
   a. If HasPrimitiveBase(V) is true, then
      i. Assert: In this case, base will never be null or undefined.
   b. Let base be ToObject(base).
   c. Return the result of calling the [[Get]] internal method of base passing
      GetReferencedName(V) and GetThisValue(V) as the arguments.
6. Else base must be an environment record.
   a. Return the result of calling the GetBindingValue (see 8.1.1) concrete method of base passing
      GetReferencedName(V) and IsStrictReference(V) as arguments.

NOTE The object that may be created in step 5.a.ii is not accessible outside of the above abstract operation and the
ordinary object [[Get]] internal method. An implementation might choose to avoid the actual creation of the object.

6.2.4.2 PutValue (V, W)

1. ReturnIfAbrupt(V).
2. ReturnIfAbrupt(W).
3. If Type(V) is not Reference, throw a ReferenceError exception.
4. Let base be the result of calling GetBase(V).
5. If IsUnresolvableReference(V), then
   a. If IsStrictReference(V) is true, then
      i. Throw ReferenceError exception.
   b. Let globalObj be the result of the abstract operation GetGlobalObject.
   c. Return the result of calling Put(globalObj, GetReferencedName(V), W, false).
6. Else if IsPropertyReference(V), then
   a. If HasPrimitiveBase(V) is true, then
      i. Assert: In this case, base will never be null or undefined.
   b. Let succeeded be the result of calling the [[Set]] internal method of base passing
      GetReferencedName(V), W, and GetThisValue(V) as arguments.
   c. ReturnIfAbrupt(succeeded).
   d. If succeeded is false and IsStrictReference(V) is true, then throw a TypeError exception.
   e. Return.
7. Else base must be a reference whose base is an environment record. So,
   a. Return the result of calling the SetMutableBinding (8.1.1) concrete method of base, passing
      GetReferencedName(V), W, and IsStrictReference(V) as arguments.
8. Return.

NOTE The object that may be created in step 6.a.ii is not accessible outside of the above algorithm and the ordinary
object [[Set]] internal method. An implementation might choose to avoid the actual creation of that object.

6.2.4.3 GetThisValue (V)

1. ReturnIfAbrupt(V).
2. If Type(V) is not Reference, return V.
3. If IsUnresolvableReference(V), throw a ReferenceError exception.
4. If IsSuperReference(V), then
   a. Return the value of the thisValue component of the reference V.
5. Return GetBase(V).

6.2.5 The Property Descriptor Specification Type

The Property Descriptor type is used to explain the manipulation and reification of Object property attributes.
Values of the Property Descriptor type are Records composed of named fields where each field’s name is an
attribute name and its value is a corresponding attribute value as specified in 6.1.6.1. In addition, any field may be present or absent.

Property Descriptor values may be further classified as data property descriptors and accessor property descriptors based upon the existence or use of certain fields. A data property descriptor is one that includes any fields named either [[Value]] or [[Writable]]. An accessor property descriptor is one that includes any fields named either [[Get]] or [[Set]]. Any property descriptor may have fields named [[Enumerable]] and [[Configurable]]. A Property Descriptor value may not be both a data property descriptor and an accessor property descriptor; however, it may be neither. A generic property descriptor is a Property Descriptor value that is neither a data property descriptor nor an accessor property descriptor. A fully populated property descriptor is one that is either an accessor property descriptor or a data property descriptor and that has all of the fields that correspond to the property attributes defined in either 6.1.6.1 Table 1 or Table 2.

A Property Descriptor may be derived from an ECMAScript object that has properties that directly correspond to the fields of a Property Descriptor. Such a derived Property Descriptor has an additional field named [[Origin]] whose value is the object from which the Property Descriptor was derived.

The following abstract operations are used in this specification to operate upon Property Descriptor values:

6.2.5.1 IsAccessorDescriptor (Desc)

When the abstract operation IsAccessorDescriptor is called with property descriptor Desc, the following steps are taken:

1. If Desc is undefined, then return false.
2. If both Desc.[[Get]] and Desc.[[Set]] are absent, then return false.
3. Return true.

6.2.5.2 IsDataDescriptor (Desc)

When the abstract operation IsDataDescriptor is called with property descriptor Desc, the following steps are taken:

1. If Desc is undefined, then return false.
2. If both Desc.[[Value]] and Desc.[[Writable]] are absent, then return false.
3. Return true.

6.2.5.3 IsGenericDescriptor (Desc)

When the abstract operation IsGenericDescriptor is called with property descriptor Desc, the following steps are taken:

1. If Desc is undefined, then return false.
2. If IsAccessorDescriptor(Desc) and IsDataDescriptor(Desc) are both false, then return true.
3. Return false.

6.2.5.4 FromPropertyDescriptor (Desc)

When the abstract operation FromPropertyDescriptor is called with property descriptor Desc, the following steps are taken:

The following algorithm assumes that Desc is a fully populated Property Descriptor, such as that returned from [[GetOwnProperty]] (see 9.1.6).

1. If Desc is undefined, then return undefined.
2. If Desc has an [[Origin]] field, then return Desc.[[Origin]].
3. Let obj be the result of the abstract operation ObjectCreate with the intrinsic object %ObjectPrototype% as its argument.
4. Assert: obj is an extensible ordinary object with no own properties.
5. If Desc has a [[Value]] field then
a. Call OrdinaryDefineOwnProperty with arguments obj, "value", and Property Descriptor {
  [[Value]]: Desc.([[Value]]), [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true
}
6. If Desc has a [[Writable]] field, then
   a. Call OrdinaryDefineOwnProperty with arguments obj, "writable", and Property Descriptor {
      [[Value]]: Desc.([[Writable]]), [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true
   }
7. If Desc has a [[Get]] field, then
   a. Call OrdinaryDefineOwnProperty with arguments obj, "get", and Property Descriptor {
      [[Value]]: Desc.([[Get]]), [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true
   }
8. If Desc has a [[Set]] field, then
   a. Call OrdinaryDefineOwnProperty with arguments obj, "set", and Property Descriptor {
      [[Value]]: Desc.([[Set]]), [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true
   }
9. If Desc has a [[Enumerable]] field, then
   a. Call OrdinaryDefineOwnProperty with arguments obj, "enumerable", and Property Descriptor {
      [[Value]]: Desc.([[Enumerable]]), [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true
   }
10. If Desc has a [[Configurable]] field, then
    a. Call OrdinaryDefineOwnProperty with arguments obj, "configurable", and Property Descriptor {
       [[Value]]: Desc.([[Configurable]]), [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true
   }
11. Return obj.

6.2.5.5 ToPropertyDescriptor ( Obj )

When the abstract operation ToPropertyDescriptor is called with object Obj, the following steps are taken:

1. ReturnIfAbrupt(Obj).
2. If Type(Obj) is not Object throw a TypeError exception.
3. Let desc be the result of creating a new Property Descriptor that initially has no fields.
4. If the result of HasProperty(Obj, "enumerable") is true, then
   a. Let enumerable be the result of Get(Obj, "enumerable").
   b. ReturnIfAbrupt(enumerable).
   c. Set the [[Enumerable]] field of desc to ToBoolean(enumerable).
5. If the result of HasProperty(Obj, "configurable") is true, then
   a. Let configurable be the result of Get(Obj, "configurable").
   b. ReturnIfAbrupt(configurable).
   c. Set the [[Configurable]] field of desc to ToBoolean(configurable).
6. If the result of HasProperty(Obj, "value") is true, then
   a. Let value be the result of Get(Obj, "value").
   b. ReturnIfAbrupt(value).
   c. Set the [[Value]] field of desc to value.
7. If the result of HasProperty(Obj, "writable") is true, then
   a. Let writable be the result of Get(Obj, "writable").
   b. ReturnIfAbrupt(writable).
   c. Set the [[Writable]] field of desc to ToBoolean(writable).
8. If the result of HasProperty(Obj, "get") is true, then
   a. Let get be the result of Get(Obj, "get").
   b. ReturnIfAbrupt(get).
   c. If IsCallable(get) is false and get is not undefined, then throw a TypeError exception.
   d. Set the [[Get]] field of desc to get.
9. If the result of HasProperty(Obj, "set") is true, then
   a. Let set be the result of Get(Obj, "set").
   b. ReturnIfAbrupt(set).
   c. If IsCallable(set) is false and set is not undefined, then throw a TypeError exception.
   d. Set the [[Set]] field of desc to set.
10. If either desc.[[Get]] or desc.[[Set]] are present, then
    a. If either desc.[[Value]] or desc.[[Writable]] are present, then throw a TypeError exception.
11. Set the [[Origin]] field of desc to Obj.
12. Return desc.
6.2.5.6 CompletePropertyDescriptor (Desc, LikeDesc)

When the abstract operation CompletePropertyDescriptor is called with Property Descriptor Desc, the following steps are taken:

1. Assert: LikeDesc is either a Property Descriptor or undefined.
2. ReturnIfAbrupt(Desc).
3. Assert: Desc is a Property Descriptor
4. If LikeDesc is undefined, then set LikeDesc to Record{
   [[Value]]: undefined, [[Writable]]: false, [[Get]]: undefined, [[Set]]: undefined, [[Enumerable]]: false, [[Configurable]]: false.
5. If either IsGenericDescriptor(Desc) or IsDataDescriptor(Desc) is true, then
   a. If Desc does not have a [[Value]] field, then set Desc. [[Value]] to LikeDesc. [[Value]].
   b. If Desc does not have a [[Writable]] field, then set Desc. [[Writable]] to LikeDesc. [[Writable]].
6. Else,
   a. If Desc does not have a [[Get]] field, then set Desc. [[Get]] to LikeDesc. [[Get]].
   b. If Desc does not have a [[Set]] field, then set Desc. [[Set]] to LikeDesc. [[Set]].
7. If Desc does not have a [[Enumerable]] field, then set Desc. [[Enumerable]] to LikeDesc. [[Enumerable]].
8. If Desc does not have a [[Configurable]] field, then set Desc. [[Configurable]] to LikeDesc. [[Configurable]].
9. Return Desc.

6.2.6 The Lexical Environment and Environment Record Specification Types

The Lexical Environment and Environment Record types are used to explain the behaviour of name resolution in nested functions and blocks. These types and the operations upon them are defined in 8.1.

7 Abstract Operations

These operations are not a part of the ECMAScript language; they are defined here to solely to aid the specification of the semantics of the ECMAScript language. Other, more specialized abstract operations are defined throughout this specification.

7.1 Type Conversion and Testing

The ECMAScript language implicitly performs automatic type conversion as needed. To clarify the semantics of certain constructs it is useful to define a set of conversion abstract operations. The conversion abstract operations are polymorphic; they can accept a value of any ECMAScript language type or of a Completion Record value. But no other specification types are used with these operations.

7.1.1 ToPrimitive

The abstract operation ToPrimitive takes an input argument and an optional argument PreferredType. The abstract operation ToPrimitive converts an input argument to a non-Object type. If an object is capable of converting to more than one primitive type, it may use the optional hint PreferredType to favour that type. Conversion occurs according to Table 9:

---

© Ecma International 2013
Table 9 — ToPrimitive Conversions

<table>
<thead>
<tr>
<th>Input Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Completion Record</td>
<td>If argument is an abrupt completion, return argument. Otherwise return ToPrimitive(argument.[[value]]) also passing the optional hint PreferredType.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Return argument (no conversion).</td>
</tr>
<tr>
<td>Null</td>
<td>Return argument (no conversion).</td>
</tr>
<tr>
<td>Boolean</td>
<td>Return argument (no conversion).</td>
</tr>
<tr>
<td>Number</td>
<td>Return argument (no conversion).</td>
</tr>
<tr>
<td>String</td>
<td>Return argument (no conversion).</td>
</tr>
<tr>
<td>Object</td>
<td>Perform the steps following this table.</td>
</tr>
</tbody>
</table>

When the InputType is Object, the following steps are taken:

1. If PreferredType was not passed, let hint be "default".
2. Else if PreferredType is hint String, let hint be "string".
3. Else PreferredType is hint Number, let hint be "number".
4. Let exoticToPrim be the result of Get(argument, @@ToPrimitive).
5. ReturnIfAbrupt(exoticToPrim).
6. If exoticToPrim is not undefined, then
   a. If IsCallable(exoticToPrim) is false, then throw a TypeError exception.
   b. Let result be the result of calling the [[Call]] internal method of exoticToPrim, with argument as thisArgument and a List containing hint as argumentsList.
   c. ReturnIfAbrupt(result).
   d. If result is an ECMAScript language value and Type(result) is not Object, then return result.
   e. Else, throw a TypeError exception.
7. If hint is "default" then, let hint be "number".
8. Return the result of OrdinaryToPrimitive(argument, hint).

When the OrdinaryToPrimitive is called with arguments O and hint, the following steps are taken:

1. Assert: Type(O) is Object
2. Assert: Type(hint) is String and its value is either "string" or "number".
3. If hint is "string", then
   a. Let tryFirst be "toString".
   b. Let trySecond be "valueOf".
4. Else,
   a. Let tryFirst be "valueOf".
   b. Let trySecond be "toString".
5. Let first be the result of Get(O, tryFirst).
6. ReturnIfAbrupt(first).
7. If IsCallable(first) is true then
   a. Let result be the result of calling the [[Call]] internal method of first, with O as thisArgument and an empty List as argumentsList.
   b. ReturnIfAbrupt(result).
   c. If result is an ECMAScript language value and Type(result) is not Object, then return result.
8. Let second be the result of Get(O, trySecond).
9. ReturnIfAbrupt(second).
10. If IsCallable(second) is true then
    a. Let result be the result of calling the [[Call]] internal method of second, with O as thisArgument and an empty List as argumentsList.
    b. ReturnIfAbrupt(result).
    c. If result is an ECMAScript language value and Type(result) is not Object, then return result.
11. Throw a TypeError exception.
NOTE When ToPrimitive is called with no hint, then it generally behaves as if the hint were Number. However, objects may over-ride this behaviour by defining a @@ToPrimitive method. Of the objects defined in this specification only Date objects (see 20.3) over-ride the default ToPrimitive behaviour. Date objects treat no hint as if the hint were String.

7.1.2 ToBoolean

The abstract operation ToBoolean converts its argument to a value of type Boolean according to Table 10:

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Completion Record</td>
<td>If argument is an abrupt completion, return the argument. Otherwise return ToBoolean(argument. [[value]])</td>
</tr>
<tr>
<td>Undefined</td>
<td>Return false</td>
</tr>
<tr>
<td>Null</td>
<td>Return false</td>
</tr>
<tr>
<td>Boolean</td>
<td>Return the input argument (no conversion)</td>
</tr>
<tr>
<td>Number</td>
<td>Return false if the argument is +0, -0 or NaN; otherwise return true.</td>
</tr>
<tr>
<td>String</td>
<td>Return false if the argument is the empty String (its length is zero); otherwise return true.</td>
</tr>
<tr>
<td>Object</td>
<td>Return true</td>
</tr>
</tbody>
</table>

7.1.3 ToNumber

The abstract operation ToNumber converts its argument to a value of type Number according to Table 11:

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Completion Record</td>
<td>If argument is an abrupt completion, return argument. Otherwise return ToNumber(argument. [[value]])</td>
</tr>
<tr>
<td>Undefined</td>
<td>Return NaN</td>
</tr>
<tr>
<td>Null</td>
<td>Return +0</td>
</tr>
<tr>
<td>Boolean</td>
<td>Return 1 if argument is true. Return +0 if argument is false.</td>
</tr>
<tr>
<td>Number</td>
<td>Return argument (no conversion).</td>
</tr>
<tr>
<td>String</td>
<td>See grammar and note below.</td>
</tr>
<tr>
<td>Object</td>
<td>Apply the following steps:</td>
</tr>
<tr>
<td>1.</td>
<td>Let primValue be ToPrimitive(argument, hint Number).</td>
</tr>
<tr>
<td>2.</td>
<td>Return ToNumber(primValue).</td>
</tr>
</tbody>
</table>

7.1.3.1 ToNumber Applied to the String Type

ToNumber applied to Strings applies the following grammar to the input String. If the grammar cannot interpret the String as an expansion of StringNumericLiteral, then the result of ToNumber is NaN.

Syntax

```
StringNumericLiteral ::=
    StrWhiteSpaceopt StrDigitopt
    StrDigitopt StrDigitStrDigitdot StrDigitStrDigit
t
StrWhiteSpace ::=
    StrWhiteSpaceChar StrWhiteSpaceopt
StrWhiteSpaceChar ::=
    StrWhiteSpaceChar
```

© Ecma International 2013
StrWhiteSpaceChar ::=
WhiteSpace
LineTerminator

StrNumericLiteral ::= StrDecimalLiteral
HexIntegerLiteral

StrDecimalLiteral ::= StrUnsignedDecimalLiteral
+ StrUnsignedDecimalLiteral
- StrUnsignedDecimalLiteral

StrUnsignedDecimalLiteral ::=
Infinity
DecimalDigits . DecimalDigits ExponentPart opt
. DecimalDigits ExponentPart opt
DecimalDigits ExponentPart opt

DecimalDigits ::= DecimalDigit

DecimalDigit ::= one of
0 1 2 3 4 5 6 7 8 9

ExponentPart ::= ExponentIndicator SignedInteger

ExponentIndicator ::= one of
 e E

SignedInteger ::= DecimalDigits
+ DecimalDigits
- DecimalDigits

HexIntegerLiteral ::=
0x HexDigit
0X HexDigit

HexDigit ::= one of
0 1 2 3 4 5 6 7 8 9 a b c d e f A B C D E F

NOTE
Some differences should be noted between the syntax of a StringNumericLiteral and a NumericLiteral (see 11.8.3):
• A StringNumericLiteral may be preceded and/or followed by white space and/or line terminators.
• A StringNumericLiteral that is decimal may have any number of leading 0 digits.
• A StringNumericLiteral that is decimal may be preceded by + or – to indicate its sign.
• A StringNumericLiteral that is empty or contains only white space is converted to +0.
• Infinity and –Infinity are recognised as a StringNumericLiteral but not as a NumericLiteral.

Runtime Semantics

The conversion of a String to a Number value is similar overall to the determination of the Number value for a numeric literal (see 11.8.3), but some of the details are different, so the process for converting a String numeric literal to a value of Number type is given here in full. This value is determined in two steps: first, a mathematical value (MV) is derived from the String numeric literal; second, this mathematical value is rounded as described below.
• The MV of StringNumericLiteral :: [empty] is 0.
• The MV of StringNumericLiteral :: StrWhiteSpace is 0.
• The MV of StringNumericLiteral :: StrWhiteSpace StrNumericLiteral StrWhiteSpace is the MV of StrNumericLiteral, no matter whether white space is present or not.
• The MV of StrNumericLiteral :: StrDecimalLiteral is the MV of StrDecimalLiteral.
• The MV of StrNumericLiteral :: HexIntegerLiteral is the MV of HexIntegerLiteral.
• The MV of StrDecimalLiteral :: StrUnsignedDecimalLiteral is the MV of StrUnsignedDecimalLiteral.
• The MV of StrDecimalLiteral :: + StrUnsignedDecimalLiteral is the MV of StrUnsignedDecimalLiteral.
• The MV of StrDecimalLiteral :: - StrUnsignedDecimalLiteral is the negative of the MV of StrUnsignedDecimalLiteral. (Note that if the MV of StrUnsignedDecimalLiteral is 0, the negative of this MV is also 0. The rounding rule described below handles the conversion of this signless mathematical zero to a floating-point +0 or –0 as appropriate.)
• The MV of StrUnsignedDecimalLiteral::Infinity is \(10^{\infty}\) (a value so large that it will round to \(\infty\)).
• The MV of StrUnsignedDecimalLiteral::DecimalDigits is the MV of DecimalDigits.
• The MV of StrUnsignedDecimalLiteral::DecimalDigits , DecNumber is the MV of the first DecimalDigits plus (the MV of the second DecimalDigits times \(10^n\)), where \(n\) is the number of characters in the second DecimalDigits.
• The MV of StrUnsignedDecimalLiteral:: ExponentPart is the MV of DecimalDigits times \(10^n\), where \(e\) is the MV of ExponentPart.
• The MV of StrUnsignedDecimalLiteral:: ExponentPart is the MV of DecimalDigits times \(10^n\), where \(n\) is the number of characters in DecimalDigits.
• The MV of StrUnsignedDecimalLiteral:: ExponentPart is the MV of DecimalDigits times \(10^n\), where \(n\) is the number of characters in DecimalDigits.
• The MV of ExponentPart:: ExponentIndicator SignedInteger is the MV of SignedInteger.
• The MV of SignedInteger :: DecimalDigits is the MV of DecimalDigits.
• The MV of SignedInteger :: + DecimalDigits is the MV of DecimalDigits.
• The MV of SignedInteger :: - DecimalDigits is the negative of the MV of DecimalDigits.
• The MV of DecimalDigit :: 0 or of HexDigit :: 0 is 0.
• The MV of DecimalDigit :: 1 or of HexDigit :: 1 is 1.
• The MV of DecimalDigit :: 2 or of HexDigit :: 2 is 2.
• The MV of DecimalDigit :: 3 or of HexDigit :: 3 is 3.
• The MV of DecimalDigit :: 4 or of HexDigit :: 4 is 4.
• The MV of DecimalDigit :: 5 or of HexDigit :: 5 is 5.
• The MV of DecimalDigit :: 6 or of HexDigit :: 6 is 6.
• The MV of DecimalDigit :: 7 or of HexDigit :: 7 is 7.
• The MV of DecimalDigit :: 8 or of HexDigit :: 8 is 8.
• The MV of DecimalDigit :: 9 or of HexDigit :: 9 is 9.
• The MV of HexDigit :: a or of HexDigit :: A is 10.
• The MV of HexDigit :: b or of HexDigit :: B is 11.
• The MV of HexDigit :: c or of HexDigit :: C is 12.
• The MV of HexDigit :: d or of HexDigit :: D is 13.
• The MV of HexDigit :: e or of HexDigit :: E is 14.
• The MV of HexDigit :: f or of HexDigit :: F is 15.
• The MV of HexIntegerLiteral :: 0x HexDigit is the MV of HexDigit.
• The MV of HexIntegerLiteral ::= 0X HexDigit is the MV of HexDigit.
• The MV of HexIntegerLiteral ::= HexIntegerLiteral HexDigit is (the MV of HexIntegerLiteral times 16) plus the MV of HexDigit.

Once the exact MV for a String numeric literal has been determined, it is then rounded to a value of the Number type. If the MV is 0, then the rounded value is +0 unless the first non white space character in the String numeric literal is ‘-‘, in which case the rounded value is −0. Otherwise, the rounded value must be the Number value for the MV (in the sense defined in 6.1.5), unless the literal includes a StrUnsignedDecimalLiteral and the literal has more than 20 significant digits, in which case the Number value may be either the Number value for the MV of a literal produced by replacing each significant digit after the 20th with a 0 digit or the Number value for the MV of a literal produced by replacing each significant digit after the 20th with a 0 digit and then incrementing the literal at the 20th digit position. A digit is significant if it is not part of an ExponentPart and:
• it is not 0; or
• there is a nonzero digit to its left and there is a nonzero digit, not in the ExponentPart, to its right.

7.1.4 ToInteger
The abstract operation ToInteger converts its argument to an integral numeric value. This abstract operation functions as follows:
1. Let number be the result of calling ToNumber on the input argument.
2. ReturnIfAbrupt(number).
3. If number is NaN, return +0.
4. If number is +0, −0, +∞, or −∞, return number.
5. Return the result of computing sign(number) × floor(abs(number)).

7.1.5 ToUint32: (Signed 32 Bit Integer)
The abstract operation ToInt32 converts its argument to one of \(2^{32}\) integer values in the range \(-2^{31}\) through \(2^{31}−1\), inclusive. This abstract operation functions as follows:
1. Let number be the result of calling ToNumber on the input argument.
2. ReturnIfAbrupt(number).
3. If number is NaN, +0, −0, +∞, or −∞, return +0.
4. Let int be sign(number) × floor(abs(number)).
5. Let int32bit be int modulo \(2^{32}\).
6. If int32bit &gt; \(2^{31}\), return int32bit − \(2^{32}\), otherwise return int32bit.

NOTE Given the above definition of ToUint32:
• The ToUint32 abstract operation is idempotent: if applied to a result that it produced, the second application leaves that value unchanged.
• ToUint32(ToInt32(x)) is equal to ToUint32(x) for all values of x. (It is to preserve this latter property that +∞ and −∞ are mapped to +0.)
• ToUint32 maps −0 to +0.

7.1.6 ToUint32: (Unsigned 32 Bit Integer)
The abstract operation ToUint32 converts its argument to one of \(2^{32}\) integer values in the range 0 through \(2^{32}−1\), inclusive. This abstract operation functions as follows:
1. Let number be the result of calling ToNumber on the input argument.
2. ReturnIfAbrupt(number).
3. If number is NaN, +0, −0, +∞, or −∞, return +0.
4. Let int be sign(number) × floor(abs(number)).
5. Let int32bit be int modulo \(2^{32}\).

NOTE Given the above definition of ToUint32:
• Step 6 is the only difference between ToUint32 and ToInt32.
• The ToUint32 abstract operation is idempotent: if applied to a result that it produced, the second application leaves that value unchanged.
• ToUint32(ToInt32(x)) is equal to ToUint32(x) for all values of x. (It is to preserve this latter property that +∞ and −∞ are mapped to +0.)
• ToUint32 maps −0 to +0.

7.1.7 ToUint16: (Unsigned 16 Bit Integer)
The abstract operation ToUint16 converts its argument to one of 2^{16} integer values in the range 0 through 2^{16}−1, inclusive. This abstract operation functions as follows:
1. Let number be the result of calling ToNumber on the input argument.
2. ReturnIfAbrupt(number).
3. If number is NaN, +0, −0, +∞, or −∞, return +0.
4. Let int16bit be int(number) modulo 2^{16}.
5. Return int16bit.

NOTE Given the above definition of ToUint16:
• The substitution of 2^{16} for 2^{32} in step 4 is the only difference between ToUint32 and ToUint16.
• ToUint16 maps −0 to +0.

7.1.8 ToString
The abstract operation ToString converts its argument to a value of type String according to Table 12:

Table 12 — ToString Conversions

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>&quot;undefined&quot;</td>
</tr>
<tr>
<td>Null</td>
<td>&quot;null&quot;</td>
</tr>
<tr>
<td>Boolean</td>
<td>If argument is true, then return &quot;true&quot;. If argument is false, then return &quot;false&quot;.</td>
</tr>
<tr>
<td>String</td>
<td>Return argument (no conversion)</td>
</tr>
<tr>
<td>Object</td>
<td>Apply the following steps:</td>
</tr>
<tr>
<td></td>
<td>1. Let primitive be ToPrimitive(argument, hint String).</td>
</tr>
<tr>
<td></td>
<td>2. Return ToString(primitive).</td>
</tr>
</tbody>
</table>

7.1.8.1 ToString Applied to the Number Type
The abstract operation ToString converts a Number m to String format as follows:
1. If m is NaN, return the String "NaN".
2. If m is +0 or −0, return the String "0".
3. If m is less than zero, return the String concatenation of the String "-" and ToString(−m).
4. If m is +∞, return the String "Infinity".
5. Otherwise, let n, k, and s be integers such that k ≥ 1, 10^{−k−1} ≤ s < 10^{k}, the Number value for x × 10^{−k} is m, and k is as small as possible. Note that k is the number of digits in the decimal representation of s, that x is not divisible by 10, and that the least significant digit of s is not necessarily uniquely determined by these criteria.
6. If k ≤ n ≤ 21, return the String consisting of the k digits of the decimal representation of s (in order, with no leading zeroes), followed by n−k occurrences of the character '0'.
7. If \(0 < n \leq 21\), return the String consisting of the most significant \(n\) digits of the decimal representation of \(s\), followed by a decimal point \(\cdot\), followed by the remaining \(k-n\) digits of the decimal representation of \(s\).

8. If \(-6 < n \leq 0\), return the String consisting of the character \('0'\), followed by a decimal point \(\cdot\), followed by \(-n\) occurrences of the character \('0'\), followed by the \(k\) digits of the decimal representation of \(s\).

9. Otherwise, if \(k = 1\), return the String consisting of the single digit of \(s\), followed by lowercase character \('e'\), followed by a plus sign \('+\) or minus sign \('-\) according to whether \(n-1\) is positive or negative, followed by the decimal representation of the integer \(\text{abs}(n-1)\) (with no leading zeroes).

10. Return the String consisting of the most significant digit of the decimal representation of \(s\), followed by a decimal point \(\cdot\), followed by the remaining \(k-1\) digits of the decimal representation of \(s\), followed by the lowercase character \('e'\), followed by a plus sign \('+\) or minus sign \('-\) according to whether \(n-1\) is positive or negative, followed by the decimal representation of the integer \(\text{abs}(n-1)\) (with its leading zeroes).

NOTE 1 The following observations may be useful as guidelines for implementations, but are not part of the normative requirements of this Standard:

- If \(x\) is any Number value other than \(-0\), then \(\text{ToNumber}(\text{ToString}(x))\) is exactly the same Number value as \(x\).
- The least significant digit of \(s\) is not always uniquely determined by the requirements listed in step 5.

NOTE 2 For implementations that provide more accurate conversions than required by the rules above, it is recommended that the following alternative version of step 5 be used as a guideline:

Otherwise, let \(n, k\), and \(s\) be integers such that \(k \geq 1, 10^{-1} \leq s < 10^{k}\); the Number value for \(s \times 10^{-k}\) is \(m\), and \(k\) is as small as possible. If there are multiple possibilities for \(s\), choose the value of \(s\) for which \(s \times 10^{-k}\) is closest in value to \(m\). If there are two such possible values of \(s\), choose the one that is even. Note that \(k\) is the number of digits in the decimal representation of \(s\) and that \(s\) is not divisible by 10.

NOTE 3 Implementers of ECMAScript may find useful the paper and code written by David M. Gay for binary-to-decimal conversion of floating-point numbers:

7.1.9 ToObject

The abstract operation \(\text{ToObject}\) converts its \(\text{argument}\) to a value of type \(\text{Object}\) according to Table 13:

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Completion Record</td>
<td>If (\text{argument}) is an abrupt completion, return (\text{argument}). Otherwise return (\text{ToObject}(\text{argument}[[\text{value}]]))).</td>
</tr>
<tr>
<td>Undefined</td>
<td>Throw a (\text{TypeError}) exception.</td>
</tr>
<tr>
<td>Null</td>
<td>Throw a (\text{TypeError}) exception.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Return a new Boolean object whose ([\text{BooleanData}]) internal data property is set to the value of (\text{argument}). See 19.3 for a description of Boolean objects.</td>
</tr>
<tr>
<td>Number</td>
<td>Return a new Number object whose ([\text{NumberData}]) internal data property is set to the value of (\text{argument}). See 20.1 for a description of Number objects.</td>
</tr>
<tr>
<td>String</td>
<td>Return a new String object whose ([\text{StringData}]) internal data property is set to the value of (\text{argument}). See 21.1 for a description of String objects.</td>
</tr>
<tr>
<td>Object</td>
<td>Return (\text{argument}) (no conversion).</td>
</tr>
</tbody>
</table>

7.1.10 ToPropertyKey

The abstract operation \(\text{ToPropertyKey}\) converts its \(\text{argument}\) to a value that can be used as a property key by performing the following steps:
1. ReturnIfAbrupt(argument).
2. If argument is an exotic Symbol Object, then
   a. Return argument.
3. Return ToString(argument).

7.1.11 ToLength

The abstract operation ToLength converts its argument to an integer suitable for use as the length of an array-like object. It performs the following steps:

1. Let len be ToInteger(argument).
2. ReturnIfAbrupt(len).
3. If len ≤ 0, then return 0.
4. Return min(len, 2^{53} - 1).

7.2 Testing and Comparison Operations

7.2.1 CheckObjectCoercible

The abstract operation CheckObjectCoercible throws an error if its argument is a value that cannot be converted to an Object using ToObject. It is defined by Table 14:

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Completion Record</td>
<td>If argument is an abrupt completion, return argument. Otherwise return CheckObjectCoercible(argument.[[value]])</td>
</tr>
<tr>
<td>Undefined</td>
<td>Throw a TypeError exception.</td>
</tr>
<tr>
<td>Null</td>
<td>Throw a TypeError exception.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Return argument</td>
</tr>
<tr>
<td>Number</td>
<td>Return argument</td>
</tr>
<tr>
<td>String</td>
<td>Return argument</td>
</tr>
<tr>
<td>Object</td>
<td>Return argument</td>
</tr>
</tbody>
</table>

7.2.2 IsCallable

The abstract operation IsCallable determines if its argument, which must be an ECMAScript language value or a Completion Record, is a callable function Object according to Table 15:

<table>
<thead>
<tr>
<th>Argument Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Completion Record</td>
<td>If argument is an abrupt completion, return argument. Otherwise return IsCallable(argument.[[value]])</td>
</tr>
<tr>
<td>Undefined</td>
<td>Return false.</td>
</tr>
<tr>
<td>Null</td>
<td>Return false.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Return false.</td>
</tr>
<tr>
<td>Number</td>
<td>Return false.</td>
</tr>
<tr>
<td>String</td>
<td>Return false.</td>
</tr>
<tr>
<td>Object</td>
<td>If argument has a [[Call]] internal method, then return true, otherwise return false.</td>
</tr>
</tbody>
</table>

7.2.3 SameValue(x, y)

The internal comparison abstract operation SameValue(x, y), where x and y are ECMAScript language values, produces true or false. Such a comparison is performed as follows:
1. ReturnIfAbrupt(x).
2. ReturnIfAbrupt(y).
3. If Type(x) is different from Type(y), return false.
4. If Type(x) is Undefined, return true.
5. If Type(x) is Null, return true.
6. If Type(x) is Number, then
   a. If x is NaN and y is NaN, return true.
   b. If x is +0 and y is -0, return false.
   c. If x is -0 and y is +0, return false.
   d. If x is the same Number value as y, return true.
   e. Return false.
7. If Type(x) is String, then
   a. If x and y are exactly the same sequence of code units (same length and same code units in corresponding positions) return true; otherwise, return false.
8. If Type(x) is Boolean, then
   a. If x and y are both true or both false, then return true; otherwise, return false.
9. Return true if x and y are the same Object value. Otherwise, return false.

7.2.4 SameValueZero(x, y)
The internal comparison abstract operation SameValueZero(x, y), where x and y are ECMAScript language values, produces true or false. Such a comparison is performed as follows:
1. ReturnIfAbrupt(x).
2. ReturnIfAbrupt(y).
3. If Type(x) is different from Type(y), return false.
4. If Type(x) is Undefined, return true.
5. If Type(x) is Null, return true.
6. If Type(x) is Number, then
   a. If x is NaN and y is NaN, return true.
   b. If x is +0 and y is -0, return true.
   c. If x is -0 and y is +0, return true.
   d. If x is the same Number value as y, return true.
   e. Return false.
7. If Type(x) is String, then
   a. If x and y are exactly the same sequence of code units (same length and same code units in corresponding positions) return true; otherwise, return false.
8. If Type(x) is Boolean, then
   a. If x and y are both true or both false, then return true; otherwise, return false.
9. Return true if x and y are the same Object value. Otherwise, return false.

NOTE SameValueZero differs from SameValue only in its treatment of +0 and -0.

7.2.5 IsConstructor
The abstract operation IsConstructor determines if its argument, which must be an ECMAScript language value or a Completion Record, is a function object with a [[Construct]] internal method.
1. ReturnIfAbrupt(argument).
2. If Type(argument) is not Object, return false.
3. If argument has a [[Construct]] internal method, return true.
4. Return false.

7.2.6 IsPropertyKey
The abstract operation IsPropertyKey determines if its argument, which must be an ECMAScript language value or a Completion Record, is a value that may be used as a property key.
1. ReturnIfAbrupt(argument).
2. If Type(argument) is String, return true.
3. If Type(argument) is Object and argument is an exotic Symbol object, return true.
4. Return `false`.

7.2.7 `IsExtensible (O)`

The abstract operation `IsExtensible` is used to determine whether additional properties can be added to the object that is `O`. A Boolean value is returned. This abstract operation performs the following steps:

1. Assert: `Type(O)` is `Object`.
2. Return the result of calling the `[[IsExtensible]]` internal method of `O`.

7.2.8 Abstract Relational Comparison

The comparison `x < y`, where `x` and `y` are values, produces `true`, `false`, or `undefined` (which indicates that at least one operand is `NaN`). In addition to `x` and `y` the algorithm takes a Boolean flag named `LeftFirst` as a parameter. The flag is used to control the order in which operations with potentially visible side-effects are performed upon `x` and `y`. It is necessary because ECMAScript specifies left to right evaluation of expressions. The default value of `LeftFirst` is `true` and indicates that the `x` parameter corresponds to an expression that occurs to the left of the `y` parameter's corresponding expression. If `LeftFirst` is `false`, the reverse is the case and operations must be performed upon `y` before `x`. Such a comparison is performed as follows:

1. Return `IfAbrupt(x)`.  
2. Return `IfAbrupt(y)`.  
3. If the `LeftFirst` flag is `true`, then
   a. Let `px` be the result of calling `ToPrimitive(x, hint Number)`.  
   b. Return `IfAbrupt(px)`.  
   c. Let `py` be the result of calling `ToPrimitive(y, hint Number)`.  
   d. Return `IfAbrupt(py)`.  
4. Else the order of evaluation needs to be reversed to preserve left to right evaluation
   a. Let `py` be the result of calling `ToPrimitive(y, hint Number)`.  
   b. Return `IfAbrupt(py)`.  
   c. Let `px` be the result of calling `ToPrimitive(x, hint Number)`.  
   d. Return `IfAbrupt(px)`.  
5. If both `px` and `py` are `Strings`, then
   a. If `px` is a prefix of `py`, return `false`. (A String value `p` is a prefix of String value `q` if `q` is the result of concatenating `p` and some other String `r`. Note that any String is a prefix of itself, because `r` may be the empty String.)  
   b. If `py` is a prefix of `px`, return `true`.
   c. Let `k` be the smallest nonnegative integer such that the character at position `k` within `px` is different from the character at position `k` within `py`. (There must be such a `k`, for neither String is a prefix of the other.)  
   d. Let `m` be the integer that is the code unit value for the character at position `k` within `px`.  
   e. Let `n` be the integer that is the code unit value for the character at position `k` within `py`.  
   f. If `m < n`, return `true`. Otherwise, return `false`.  
6. Else,
   a. Let `nx` be the result of calling `ToNumber(px)`. Because `px` and `py` are primitive values evaluation order is not important.
   b. Let `ny` be the result of calling `ToNumber(py)`.  
   c. If `nx` is `NaN`, return `undefined`.  
   d. If `ny` is `NaN`, return `undefined`.  
   e. If `nx` and `ny` are the same `Number` value, return `false`.  
   f. If `nx` is `+0` and `ny` is `-0`, return `false`.  
   g. If `nx` is `-0` and `ny` is `+0`, return `false`.  
   h. If `nx` is `
     +\infty`, return `false`.  
   i. If `ny` is `
     +\infty`, return `true`.  
   j. If `ny` is `-\infty`, return `false`.  
   k. If `nx` is `-\infty`, return `true`.  
   l. If the mathematical value of `nx` is less than the mathematical value of `ny` — note that these mathematical values are both finite and not both zero — return `true`. Otherwise, return `false`.  

© Ecma International 2013
NOTE 1  Step 5 differs from step 11 in the algorithm for the addition operator + (11.6.1) in using and instead of or.

NOTE 2  The comparison of Strings uses a simple lexicographic ordering on sequences of code unit values. There is no attempt to use the more complex, semantically oriented definitions of character or string equality and collating order defined in the Unicode specification. Therefore String values that are canonically equal according to the Unicode standard could test as unequal. In effect this algorithm assumes that both Strings are already in normalised form. Also, note that for strings containing supplementary characters, lexicographic ordering on sequences of UTF-16 code unit values differs from that on sequences of code point values.

7.2.9  Abstract Equality Comparison

The comparison $x \equiv y$, where $x$ and $y$ are values, produces true or false. Such a comparison is performed as follows:

1. If Type($x$) is the same as Type($y$), then
   a. Return the result of performing Strict Equality Comparison $x === y$.
2. If $x$ is null and $y$ is undefined, return true.
3. If $x$ is undefined and $y$ is null, return true.
4. If Type($x$) is Number and Type($y$) is String, return the result of the comparison $x \equiv \text{ToNumber}(y)$.
5. If Type($x$) is String and Type($y$) is Number, return the result of the comparison $\text{ToNumber}(x) \equiv y$.
6. If Type($x$) is Boolean, return the result of the comparison $\text{ToNumber}(x) \equiv y$.
7. If Type($y$) is Boolean, return the result of the comparison $x \equiv \text{ToNumber}(y)$.
8. If Type($x$) is either String or Number and Type($y$) is Object, return the result of the comparison $x \equiv \text{ToPrimitive}(y)$.
9. If Type($x$) is Object and Type($y$) is either String or Number, return the result of the comparison $\text{ToPrimitive}(x) \equiv y$.
10. Return false.

7.2.10  Strict Equality Comparison

The comparison $x === y$, where $x$ and $y$ are values, produces true or false. Such a comparison is performed as follows:

1. If Type($x$) is different from Type($y$), return false.
2. If Type($x$) is Undefined, return true.
3. If Type($x$) is Null, return true.
4. If Type($x$) is Number, then
   a. If $x$ is NaN, return false.
   b. If $y$ is NaN, return false.
   c. If $x$ is the same Number value as $y$, return true.
   d. If $x$ is +0 and $y$ is -0, return true.
   e. If $x$ is -0 and $y$ is +0, return true.
   f. Return false.
5. If Type($x$) is String, then
   a. If $x$ and $y$ are exactly the same sequence of characters (same length and same characters in corresponding positions), return true.
   b. Else, return false.
6. If Type($x$) is Boolean, then
   a. If $x$ and $y$ are both true or both false, return true.
   b. Else, return false.
7. If $x$ and $y$ are the same Object value, return true.
8. Return false.

NOTE  This algorithm differs from the SameValue Algorithm (7.2.3) in its treatment of signed zeroes and NaNs.
7.3 Operations on Objects

7.3.1 Get (O, P)

The abstract operation Get is used to retrieve the value of a specific property of an object. The operation is called with arguments $O$ and $P$ where $O$ is the object and $P$ is the property key. This abstract operation performs the following steps:

1. Assert: Type($O$) is Object.
2. Assert: IsPropertyKey($P$) is true.
3. Return the result of calling the [[Get]] internal method of $O$ passing $P$ and $O$ as the arguments.

7.3.2 Put (O, P, V, Throw)

The abstract operation Put is used to set the value of a specific property of an object. The operation is called with arguments $O$, $P$, $V$, and $Throw$ where $O$ is the object, $P$ is the property key, $V$ is the new value for the property and $Throw$ is a Boolean flag. This abstract operation performs the following steps:

1. Assert: Type($O$) is Object.
2. Assert: IsPropertyKey($P$) is true.
3. Assert: Type($Throw$) is Boolean.
4. Let success be the result of calling the [[Set]] internal method of $O$ passing $P$, $V$, and $O$ as the arguments.
5. ReturnIfAbrupt(success).
6. If success is false and $Throw$ is true, then throw a TypeError exception.
7. Return success.

7.3.3 CreateOwnProperty (O, P, V)

The abstract operation CreateOwnProperty is used to create a new own property of an object. The operation is called with arguments $O$, $P$, and $V$ where $O$ is the object, $P$ is the property key, and $V$ is the value for the property. This abstract operation performs the following steps:

1. Assert: Type($O$) is Object.
2. Assert: IsPropertyKey($P$) is true.
3. Assert: $O$ does not have an own property whose key is $P$.
4. Let newDesc be the Property Descriptor {[[Value]]: V, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}.
5. Return the result of calling the [[DefineOwnProperty]] internal method of $O$ passing $P$ and newDesc as arguments.

NOTE This abstract operation creates a property whose attributes are set to the same defaults used for properties created by the ECMAScript language assignment operator.

7.3.4 DefinePropertyOrThrow (O, P, desc)

The abstract operation DefinePropertyOrThrow is used to call the [[DefineOwnProperty]] internal method of an object in a manner that will throw a TypeError exception if the requested property update cannot be performed. The operation is called with arguments $O$, $P$, and $desc$ where $O$ is the object, $P$ is the property key, and $desc$ is the Property Descriptor for the property. This abstract operation perform, the following steps:

1. Assert: Type($O$) is Object.
2. Assert: IsPropertyKey($P$) is true.
3. Let success be the result of calling the [[DefineOwnProperty]] internal method of $O$ passing $P$ and $desc$ as arguments.
4. ReturnIfAbrupt(success).
5. If success is false, then throw a TypeError exception.
7.3.5  DeletePropertyOrThrow (O, P)

The abstract operation DeletePropertyOrThrow is used to remove a specific own property of an object. It throws an exception if the property is not configurable. The operation is called with arguments \( O \) and \( P \) where \( O \) is the object and \( P \) is the property key. This abstract operation performs the following steps:

1. Assert: \( \text{Type}(O) \) is Object.
2. Assert: IsPropertyKey\((P)\) is true.
3. Let \( \text{success} \) be the result of calling the [[Delete]] internal method of \( O \) passing \( P \) as the argument.
4. ReturnIfAbrupt\( (\text{success}) \).
5. If \( \text{success} \) is false, then throw a TypeError exception.
6. Return \( \text{success} \).

7.3.6  HasProperty (O, P)

The abstract operation HasProperty is used to determine whether an object has a property with the specified property key. The property may be either an own or inherited. A Boolean value is returned. The operation is called with arguments \( O \) and \( P \) where \( O \) is the object and \( P \) is the property key. This abstract operation performs the following steps:

1. Assert: \( \text{Type}(O) \) is Object.
2. Assert: IsPropertyKey\((P)\) is true.
3. Return the result of calling the [[HasProperty]] internal method of \( O \) with argument \( P \).

7.3.7  GetMethod (O, P)

The abstract operation GetMethod is used to get the value of a specific property of an object when the value of the property is expected to be a function. The operation is called with arguments \( O \) and \( P \) where \( O \) is the object, \( P \) is the property key. This abstract operation performs the following steps:

1. Assert: \( \text{Type}(O) \) is Object.
2. Assert: IsPropertyKey\((P)\) is true.
3. Let \( \text{func} \) be the result of calling the [[Get]] internal method of \( O \) passing \( P \) and \( O \) as the arguments.
4. ReturnIfAbrupt\( (\text{func}) \).
5. If \( \text{func} \) is undefined, then return undefined.
6. If IsCallable\( (\text{func}) \) is false, then throw a TypeError exception.
7. Return \( \text{func} \).

7.3.8  Invoke(O, P, [args])

The abstract operation Invoke is used to call a method property of an object. The operation is called with arguments \( O, P \), and optionally \( \text{args} \) where \( O \) serves as both the lookup point for the property and the this value of the call, \( P \) is the property key, and \( \text{args} \) is the list of arguments values passed to the method. If \( \text{args} \) is not present, an empty List is used as its value. This abstract operation performs the following steps:

1. Assert: \( P \) is a valid property key.
2. If \( \text{args} \) was not passed, then let \( \text{args} \) be a new empty List.
3. If \( \text{Type}(O) \) is Object then,
   a. Let base be \( O \).
4. Else,
   a. Let base be ToObject\( (O) \).
5. ReturnIfAbrupt\( (\text{base}) \).
6. Return the result of calling the [[Invoke]] internal method of \( \text{base} \) passing arguments \( P, \text{args}, \) and \( O \).

7.3.9  SetIntegrityLevel (O, level)

The abstract operation SetIntegrityLevel is used to fix the set of own properties of an object. This abstract operation performs the following steps:

1. Assert: \( \text{Type}(O) \) is Object.
2. Assert: level is either "sealed" or "frozen".
3. Let keys be the result of calling the `[[OwnPropertyKeys]]` internal method of O.
4. ReturnIfAbrupt(keys).
5. Let pendingException be undefined.
6. If level is "sealed", then
   a. Repeat for each element k of keys,
      i. Let status be the result of `DefinePropertyOrThrow(O, k, PropertyDescriptor{[[Configurable]]: false}).`
      ii. If status is an abrupt completion, then
          1. If pendingException is undefined, then set pendingException to status.
   7. Else level is "frozen", then
      a. Repeat for each element k of keys,
         i. Let status be the result of calling the `[[GetOwnProperty]]` internal method of O with k.
         ii. If status is an abrupt completion, then
             1. If pendingException is undefined, then set pendingException to status.
         iii. Else,
             1. Let currentDesc be status.[[value]].
             2. If currentDesc is not undefined, then
                a. If IsAccessorDescriptor(currentDesc) is true, then
                   i. Let desc be PropertyDescriptor{[[Configurable]]: false}.
                b. Else,
                   i. Let desc be PropertyDescriptor[ [[Configurable]]: false, [[Writable]]: false ].
                c. Let status be the result of `DefinePropertyOrThrow(O, k, desc)`.
             d. If status is an abrupt completion, then
                i. If pendingException is undefined, then set pendingException to status.
   8. If pendingException is not undefined, then return pendingException.
9. Return the result of calling the `[[PreventExtensions]]` internal method of O.

7.3.10 TestIntegrityLevel (O, level)

The abstract operation TestIntegrityLevel is used to determine if the set of own properties of an object are fixed. This abstract operation performs the following steps:

1. Assert: Type(O) is Object.
2. Assert: level is either "sealed" or "frozen".
3. Let status be the result of `IsExtensible(O)`.
4. ReturnIfAbrupt(status).
5. If status is true, then return false.
6. NOTE: If the object is extensible, none of its properties are examined.
7. Let keys be the result of calling the `[[OwnPropertyKeys]]` internal method of O.
8. ReturnIfAbrupt(keys).
9. Let pendingException be undefined.
10. Let configurable be false.
11. Let writable be false.
12. Repeat for each element k of keys,
    a. Let status be the result of calling the `[[GetOwnProperty]]` internal method of O with k.
    b. If status is an abrupt completion, then
       i. If pendingException is undefined, then set pendingException to status.
       ii. Let configurable be true.
    c. Else,
       i. Let currentDesc be status.[[value]].
       ii. If currentDesc is not undefined, then
           1. Set configurable to configurable logically or with currentDesc.[[Configurable]]
           2. If IsDataDescriptor(currentDesc) is true, then
              a. Set writable to writable logically or with currentDesc.[[Writable]].
    13. If pendingException is not undefined, then return pendingException.
14. If level is "frozen" and writable is true, then return false.
15. If configurable is true, then return false.
16. Return true.

7.3.11 CreateArrayFromList (elements)

The abstract operation CreateArrayFromList is used to create an Array object whose elements are provided by an internal List. This abstract operation performs the following steps:

1. Assert: elements is a List whose elements are all ECMAScript language values.
2. Let array be the result of the abstract operation ArrayCreate with argument 0.
3. Let n be 0.
4. For each element e of elements
   a. Let status be the result of CreateOwnDataProperty(array, ToString(n), e).
   b. Assert: status is true.
   c. Increment n by 1.
5. Return array.

7.3.12 CreateListFromArrayLike (obj)

The abstract operation CreateListFromArrayLike is used to create a List value whose elements are provided by the indexed properties of an Array-like Object. This abstract operation performs the following steps:

1. If Type(obj) is not Object, then throw a TypeError exception.
2. Let len be the result of Get(obj, "length").
3. Let n be ToInteger(len).
4. ReturnIfAbrupt(n).
5. Let list be an empty List.
6. Let index be 0.
7. Repeat while index < n
   a. Let indexName be ToString(index).
   b. Let next be the result of Get(obj, indexName).
   c. ReturnIfAbrupt(next).
   d. Append next as the last element of list.
   e. Set index to index + 1.
8. Return list.

7.3.13 OrdinaryHasInstance (C, O)

The abstract operation OrdinaryHasInstance implements the default algorithm for determining if an object O inherits from the instance object inheritance path provided by constructor C. This abstract operation performs the following steps:

1. If IsCallable(C) is false, return false.
2. If C has a [[BoundTargetFunction]] internal data property, then
   a. Let BC be the value of C’s [[BoundTargetFunction]] internal data property.
   b. Return the result of instanceofOperator(O, BC) (see 12.8.1).
3. If Type(O) is not Object, return false.
4. Let P be the result of Get(C, "prototype").
5. ReturnIfAbrupt(P).
6. If Type(P) is not Object, throw a TypeError exception.
7.Repeat
   a. Set O to the result of calling the [[GetInheritance]] internal method of O with no arguments.
   b. ReturnIfAbrupt(O).
   c. If O is null, return false.
   d. If SameValue(P, O) is true, return true.

7.3.14 GetPrototypeFromConstructor ( constructor, intrinsicDefaultProto )

The abstract operation GetPrototypeFromConstructor determines the [[Prototype]] value that should be used to create an object corresponding to a specific constructor. The value is retrieved from the constructor's
prototype property, if it exists. Otherwise the supplied default is used for [[Prototype]]. This abstract operation performs the following steps:

1. Assert: intrinsicDefaultProto is a string value that is this specification’s name of an intrinsic object. The corresponding object must be an intrinsic that is intended to be used as the [[Prototype]] value of an object.
2. If IsConstructor (constructor) is false, then throw a TypeError exception.
3. Let proto be the result of Get (constructor, "prototype").
4. ReturnIfAbrupt (proto).
5. If Type (proto) is not Object, then
   a. If constructor has a [[Realm]] internal data property, let realm be constructor’s [[Realm]].
   b. Else,
      i. Let ctx be the running execution context.
      ii. Let realm be ctx’s Realm.
   c. Let proto be realm’s intrinsic object named intrinsicDefaultProto.
6. Return proto.

NOTE If constructor does not supply a [[Prototype]] value, the default value that is used is obtained from the Code Realm of the constructor function rather than from the running execution context. This accounts for the possibility that a built-in @@create method from a different Code Realm might be installed on constructor.

7.3.15 OrdinaryCreateFromConstructor (constructor, intrinsicDefaultProto, internalDataList)

The abstract operation OrdinaryCreateFromConstructor creates an ordinary object whose [[Prototype]] value is retrieved from a constructor’s prototype property, if it exists. Otherwise the supplied default is used for [[Prototype]]. The optional internalDataList is a List of the names of internal data property names that should be defined as part of the object. If the list is not provided, an empty List is used. This abstract operation performs the following steps:

1. Assert: intrinsicDefaultProto is a string value that is this specification’s name of an intrinsic object. The corresponding object must be an intrinsic that is intended to be used as the [[Prototype]] value of an object.
2. Let proto be the result of GetPrototypeFromConstructor (constructor, intrinsicDefaultProto).
3. ReturnIfAbrupt (proto).
4. Return the result of the abstract operation ObjectCreate (proto, internalDataList).
of the global environment’s identifier bindings. This global object is the value of a global environment’s `this` binding. As ECMAScript code is executed, additional properties may be added to the global object and the initial properties may be modified.

A method environment is a Lexical Environment that corresponds to the invocation of an ECMAScript function object that establishes a new `this` binding. A method environment also captures the state necessary to support `super` method invocations.

Lexical Environments and Environment Record values are purely specification mechanisms and need not correspond to any specific artefact of an ECMAScript implementation. It is impossible for an ECMAScript program to directly access or manipulate such values.

### 8.1.1 Environment Records

There are two primary kinds of Environment Record values used in this specification: declarative environment records and object environment records. Declarative environment records are used to define the effect of ECMAScript language syntactic elements such as `FunctionDeclarations`, `VariableDeclarations`, and `Catch` clauses that directly associate identifier bindings with ECMAScript language values. Object environment records are used to define the effect of ECMAScript elements such as `WithStatement` that associate identifier bindings with the properties of some object. Global Environment Records and Function Environment Records are specializations that are used for specifically for `Script` global declarations and for top-level declarations within functions.

For specification purposes Environment Record values can be thought of as existing in a simple object-oriented hierarchy where Environment Record is an abstract class with three concrete subclasses, declarative environment record, object environment record, and global environment record. Function environment records are a subclass of declarative environment record. The abstract class includes the abstract specification methods defined in Table 16. These abstract methods have distinct concrete algorithms for each of the concrete subclasses.
Table 16 — Abstract Methods of Environment Records

<table>
<thead>
<tr>
<th>Method</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>HasBinding(N)</td>
<td>Determine if an environment record has a binding for an identifier. Return true if it does and false if it does not. The String value N is the text of the identifier.</td>
</tr>
<tr>
<td>CreateMutableBinding(N, D)</td>
<td>Create a new but uninitialised mutable binding in an environment record. The String value N is the text of the bound name. If the optional Boolean argument D is true the binding may be subsequently deleted.</td>
</tr>
<tr>
<td>CreateImmutableBinding(N)</td>
<td>Create a new but uninitialised immutable binding in an environment record. The String value N is the text of the bound name.</td>
</tr>
<tr>
<td>InitialiseBinding(N,V)</td>
<td>Set the value of an already existing but uninitialised binding in an environment record. The String value N is the text of the bound name. V is the value for the binding and is a value of any ECMAScript language type.</td>
</tr>
<tr>
<td>SetMutableBinding(N,V, S)</td>
<td>Set the value of an already existing mutable binding in an environment record. The String value N is the text of the bound name. V is the value for the binding and may be a value of any ECMAScript language type. S is a Boolean flag. If S is true and the binding cannot be set throw a TypeError exception. S is used to identify strict mode references.</td>
</tr>
<tr>
<td>GetBindingValue(N,S)</td>
<td>Returns the value of an already existing binding from an environment record. The String value N is the text of the bound name. S is used to identify strict mode references. If S is true and the binding does not exist or is uninitialised throw a ReferenceError exception.</td>
</tr>
<tr>
<td>DeleteBinding(N)</td>
<td>Delete a binding from an environment record. The String value N is the text of the bound name. If a binding for N exists, remove the binding and return true. If the binding exists but cannot be removed return false. If the binding does not exist return true.</td>
</tr>
<tr>
<td>HasThisBinding()</td>
<td>Determine if an environment record establishes a this binding. Return true if it does and false if it does not.</td>
</tr>
<tr>
<td>HasSuperBinding()</td>
<td>Determine if an environment record establishes a super method binding. Return true if it does and false if it does not.</td>
</tr>
<tr>
<td>WithBaseObject()</td>
<td>If this environment record is associated with a with statement, return the with object. Otherwise, return undefined.</td>
</tr>
</tbody>
</table>

8.1.1.1 Declarative Environment Records

Each declarative environment record is associated with an ECMAScript program scope containing variable, constant, let, class, module, import, and/or function declarations. A declarative environment record binds the set of identifiers defined by the declarations contained within its scope.

The behaviour of the concrete specification methods for Declarative Environment Records is defined by the following algorithms.

8.1.1.1.1 HasBinding(N)

The concrete environment record method HasBinding for declarative environment records simply determines if the argument identifier is one of the identifiers bound by the record:

1. Let envRec be the declarative environment record for which the method was invoked.
2. If envRec has a binding for the name that is the value of N, return true.
3. Return false.

8.1.1.1.2 CreateMutableBinding (N, D)

The concrete Environment Record method CreateMutableBinding for declarative environment records creates a new mutable binding for the name \( N \) that is uninitialised. A binding must not already exist in this Environment Record for \( N \). If Boolean argument \( D \) is provided and has the value true the new binding is marked as being subject to deletion.

1. Let \( envRec \) be the declarative environment record for which the method was invoked.
2. Assert: \( envRec \) does not already have a binding for \( N \).
3. Create a mutable binding in \( envRec \) for \( N \) and record that it is uninitialised. If \( D \) is true record that the newly created binding may be deleted by a subsequent DeleteBinding call.
4. Return NormalCompletion(\emptyset).

8.1.1.1.3 CreateImmutableBinding (N)

The concrete Environment Record method CreateImmutableBinding for declarative environment records creates a new immutable binding for the name \( N \) that is uninitialised. A binding must not already exist in this environment record for \( N \).

1. Let \( envRec \) be the declarative environment record for which the method was invoked.
2. Assert: \( envRec \) does not already have a binding for \( N \).
3. Create an immutable binding in \( envRec \) for \( N \) and record that it is uninitialised.

8.1.1.1.4 InitialiseBinding (N,V)

The concrete Environment Record method InitialiseBinding for declarative environment records is used to set the bound value of the current binding of the identifier whose name is the value of the argument \( N \) to the value of argument \( V \). An uninitialised binding for \( N \) must already exist.

1. Let \( envRec \) be the declarative environment record for which the method was invoked.
2. Assert: \( envRec \) must have an uninitialised binding for \( N \).
3. Set the bound value for \( N \) in \( envRec \) to \( V \).
4. Record that the binding for \( N \) in \( envRec \) has been initialised.

8.1.1.1.5 SetMutableBinding (N,V,S)

The concrete Environment Record method SetMutableBinding for declarative environment records attempts to change the bound value of the current binding of the identifier whose name is the value of the argument \( N \) to the value of argument \( V \). A binding for \( N \) must already exist. If the binding is an immutable binding, a TypeError is thrown if \( S \) is true.

1. Let \( envRec \) be the declarative environment record for which the method was invoked.
2. Assert: \( envRec \) must have a binding for \( N \).
3. If the binding for \( N \) in \( envRec \) has not yet been initialised throw a ReferenceError exception.
4. Else if the binding for \( N \) in \( envRec \) is a mutable binding, change its bound value to \( V \).
5. Else this must be an attempt to change the value of an immutable binding so if \( S \) is true throw a TypeError exception.
6. Return NormalCompletion(\emptyset).

8.1.1.1.6 GetBindingValue(N,S)

The concrete Environment Record method GetBindingValue for declarative environment records simply returns the value of its bound identifier whose name is the value of the argument \( N \). The binding must already exist. If \( S \) is true and the binding is an uninitialised immutable binding throw a ReferenceError exception.

1. Let \( envRec \) be the declarative environment record for which the method was invoked.
2. Assert: \( envRec \) has a binding for \( N \).
3. If the binding for \( N \) in \( envRec \) is an uninitialised binding, then
   a. If \( S \) is false, return the value undefined, otherwise throw a ReferenceError exception.
4. Else,
   a. Return the value currently bound to $N$ in $envRec$.

8.1.1.1.7 DeleteBinding ($N$)

The concrete Environment Record method DeleteBinding for declarative environment records can only delete bindings that have been explicitly designated as being subject to deletion.

1. Let $envRec$ be the declarative environment record for which the method was invoked.
2. If $envRec$ does not have a binding for the name that is the value of $N$, return true.
3. If the binding for $N$ in $envRec$ cannot be deleted, return false.
4. Remove the binding for $N$ from $envRec$.
5. Return true.

8.1.1.1.8 HasThisBinding()

Regular Declarative Environment Records do not provide a this binding.

1. Return false.

8.1.1.1.9 HasSuperBinding()

Regular Declarative Environment Records do not provide a super binding.

1. Return false.

8.1.1.1.10 WithBaseObject()

Declarative Environment Records always return undefined as their WithBaseObject.

1. Return undefined.

8.1.1.2 Object Environment Records

Each object environment record is associated with an object called its binding object. An object environment record binds the set of string identifier names that directly correspond to the property names of its binding object. Property keys that are not strings in the form of an IdentifierName are not included in the set of bound identifiers. Both own and inherited properties are included in the set regardless of the setting of their [[Enumerable]] attribute. Because properties can be dynamically added and deleted from objects, the set of identifiers bound by an object environment record may potentially change as a side-effect of any operation that adds or deletes properties. Any bindings that are created as a result of such a side-effect are considered to be a mutable binding even if the Writable attribute of the corresponding property has the value false. Immutable bindings do not exist for object environment records.

Object environment records also have a possibly empty List of strings called unscopables. The strings in this List are exclude from the environment records set of bound names, regardless of whether or not they exist as property keys of its binding object.

Object environment records created for with statements (13.10) can provide their binding object as an implicit this value for use in function calls. The capability is controlled by a withEnvironment Boolean value that is associated with each object environment record. By default, the value of withEnvironment is false for any object environment record.

The behaviour of the concrete specification methods for Object Environment Records is defined by the following algorithms.

8.1.1.2.1 HasBinding($N$)

The concrete Environment Record method HasBinding for object environment records determines if its associated binding object has a property whose name is the value of the argument $N$:
1. Let `envRec` be the object environment record for which the method was invoked.
2. If `N` is an element of `envRec`'s `unscopables`, then return `false`.
3. Let `bindings` be the binding object for `envRec`.
4. Return the result of `HasProperty(bindings, N)`.

8.1.1.2.2 CreateMutableBinding (N, D)

The concrete Environment Record method CreateMutableBinding for object environment records creates in an environment record's associated binding object a property whose name is the String value and initialises it to the value `undefined`. If Boolean argument `D` is provided and has the value `true` the new property's `[[Configurable]]` attribute is set to `true`, otherwise it is set to `false`.

1. Let `envRec` be the object environment record for which the method was invoked.
2. Let `bindings` be the binding object for `envRec`.
3. If `D` is `true` then let `configValue` be `true` otherwise let `configValue` be `false`.
4. Return the result of `DefinePropertyOrThrow(bindings, N, Property Descriptor {[[Value]]: undefined, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: configValue})`.

NOTE Normally `envRec` will not have a binding for `N` but if it does, the semantics of `DefinePropertyOrThrow` may result in an existing binding being replaced or shadowed or cause an abrupt completion to be returned.

8.1.1.2.3 CreateImmutableBinding (N)

The concrete Environment Record method CreateImmutableBinding is never used within this specification in association with Object environment records.

8.1.1.2.4 InitialiseBinding (N,V)

The concrete Environment Record method InitialiseBinding for object environment records is used to set the bound value of the current binding of the identifier whose name is the value of the argument `N` to the value of argument `V`. An uninitialised binding for `N` must already exist.

1. Let `envRec` be the object environment record for which the method was invoked.
2. Let `bindings` be the binding object for `envRec`.
3. Record that the binding for `N` in `envRec` has been initialised.
4. Return the result of calling the `SetMutableBinding` concrete method of `envRec` with `N`, `V`, and `false` as arguments.

8.1.1.2.5 SetMutableBinding (N,V,S)

The concrete Environment Record method SetMutableBinding for object environment records attempts to set the value of the environment record's associated binding object's property whose name is the value of the argument `N` to the value of argument `V`. A property named `N` normally already exists but if it does not or is not currently writable, error handling is determined by the value of the Boolean argument `S`.

1. Let `envRec` be the object environment record for which the method was invoked.
2. Let `bindings` be the binding object for `envRec`.
3. Return the result of `Put(bindings, N, V, and S)`.

8.1.1.2.6 GetBindingValue(N,S)

The concrete Environment Record method GetBindingValue for object environment records returns the value of its associated binding object's property whose name is the String value of the argument identifier `N`. The property should already exist but if it does not the result depends upon the value of the `S` argument:

1. Let `envRec` be the object environment record for which the method was invoked.
2. Let `bindings` be the binding object for `envRec`.
3. Return the result of `HasProperty(bindings, N)`.
4. If `value is false`, then

Commented [AWB9]: This probably needs a `D` option argument, just like createMutableEnvironment
a. If S is false, return the value undefined, otherwise throw a ReferenceError exception.

6. Return the result of Get(bindings, N).

8.1.1.2.7 DeleteBinding (N)

The concrete Environment Record method DeleteBinding for object environment records can only delete bindings that correspond to properties of the environment object whose [[Configurable]] attribute have the value true.

1. Let envRec be the object environment record for which the method was invoked.
2. Let bindings be the binding object for envRec.
3. Return the result of calling the [[Delete]] internal method of bindings passing N as the argument.

8.1.1.2.8 HasThisBinding ()

Regular Object Environment Records do not provide a this binding.

1. Return false.

8.1.1.2.9 HasSuperBinding ()

Regular Object Environment Records do not provide a super binding.

1. Return false.

8.1.1.2.10 WithBaseObject()

Object Environment Records return undefined as their WithBaseObject unless their withEnvironment flag is true.

1. Let envRec be the object environment record for which the method was invoked.
2. If the withEnvironment flag of envRec is true, return the binding object for envRec.
3. Otherwise, return undefined.

8.1.1.3 Function Environment Records

A function environment record is a declarative environment record that is used to represent the outer most scope of a function that provides a this binding. In addition to its identifier bindings, a function environment record contains the this value used within its scope. If such a function references super, its function environment record also contains the state that is used to perform super method invocations from within the function.

Function environment records store their this binding as the value of their thisValue. If the associated function references super, the environment record stores in HomeObject the object that the function is bound to as a method and in MethodName the property key used for unqualified super invocations from within the function. The default value for HomeObject and MethodName is undefined.

Methods environment records support all of Declarative Environment Record methods listed in Table 16 and share the same specifications for all of those methods except for HasThisBinding and HasSuperBinding. In addition, declarative environment records support the methods listed in Table 17:

<table>
<thead>
<tr>
<th>Method</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetThisBinding()</td>
<td>Return the value of this environment record’s this binding.</td>
</tr>
<tr>
<td>GetSuperBase()</td>
<td>Return the object that is the base for super property accesses bound in this environment record. The object is derived from this environment record’s HomeObject binding. If the value is Empty, return undefined.</td>
</tr>
<tr>
<td>GetMethodName()</td>
<td>Return the value of this environment record’s MethodName binding.</td>
</tr>
</tbody>
</table>
The behaviour of the additional concrete specification methods for Function Environment Records is defined by the following algorithms:

8.1.1.3.1 HasThisBinding ()
Function Environment Records always provide a `this` binding.
1. Return `true`.

8.1.1.3.2 HasSuperBinding ()
1. If this environment record’s `HomeObject` has the value `Empty`, then return `false`. Otherwise, return `true`.

8.1.1.3.3 GetThisBinding ()
1. Return the value of this environment record’s `thisValue`.

8.1.1.3.4 GetSuperBase ()
1. Let `home` be the value of this environment record’s `HomeObject`.
2. If `home` has the value `Empty`, then return `undefined`.
3. Assert Type(`home`) is Object.
4. Return the result of calling `home`’s `[[GetInheritance]]` internal method.

8.1.1.3.5 GetMethodName ()
1. Return the value of this environment record’s `MethodName`.

8.1.1.4 Global Environment Records
A global environment record is used to represent the outermost scope that is shared by all of the ECMAScript `Script` elements that are processed in a common Realm (8.2). A global environment provides the bindings for built-in globals (clause 18), properties of the global object, and for all declarations that are not function code and that occur within `Script` productions.

A global environment record is logically a single record but it is specified as a composite encapsulating an object environment record and a declarative environment record. The object environment record has as its base object the global object of the associated Realm. This global object is also the value of the global environment record’s `thisValue`. The object environment record component of a global environment record contains the bindings for all built-in globals (clause 18) and all bindings introduced by a `FunctionDeclaration` or `VariableStatement` contained in global code. The bindings for all other ECMAScript declarations in global code are contained in the declarative environment record component of the global environment record.

Properties may be created directly on a global object. Hence, the object environment record component of a global environment record may contain both bindings created explicitly by `FunctionDeclaration` or `VariableStatement` declarations and binding created implicitly as properties of the global object. In order to identify which bindings were explicitly created using declarations, a global environment record maintains a list of the names bound using its `CreateGlobalVarBindings` and `CreateGlobalFunctionBindings` concrete methods.

Global environment records have the additional state components listed in Table 18 and the additional methods listed in Table 19.
Table 18 -- Components of Global Environment Records

<table>
<thead>
<tr>
<th>Component</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ObjectEnvironment</td>
<td>A Object Environment Record whose base object is the global object. Contains global built-in bindings as well as bindings for FunctionDeclaration or VariableStatement declarations in global code for the associated Realm.</td>
</tr>
<tr>
<td>DeclarativeEnvironment</td>
<td>A Declarative Environment Record that contains bindings for all declarations in global for the associated Realm code except for FunctionDeclaration and VariableStatement declarations.</td>
</tr>
<tr>
<td>VarNames</td>
<td>A List containing the string names bound by FunctionDeclaration or VariableStatement declarations in global code for the associated Realm.</td>
</tr>
</tbody>
</table>

Table 19 — Additional Methods of Global Environment Records

<table>
<thead>
<tr>
<th>Method</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetThisBinding()</td>
<td>Return the value of this environment record’s this binding.</td>
</tr>
<tr>
<td>HasVarDeclaration (N)</td>
<td>Determines if the argument identifier has a binding in this environment record that was created using a VariableStatement or a FunctionDeclaration.</td>
</tr>
<tr>
<td>HasLexicalDeclaration (N)</td>
<td>Determines if the argument identifier has a binding in this environment record that was created using a lexical declaration such as a LexicalDeclaration or a ClassDeclaration.</td>
</tr>
<tr>
<td>CanDeclareGlobalVar (N)</td>
<td>Determines if a corresponding CreateGlobalVarBinding call would succeed if called for the same argument N.</td>
</tr>
<tr>
<td>CanDeclareGlobalFunction (N)</td>
<td>Determines if a corresponding CreateGlobalFunctionBinding call would succeed if called for the same argument N.</td>
</tr>
<tr>
<td>CreateGlobalVarBinding(N, D)</td>
<td>Used to create global var bindings in the ObjectEnvironmentComponent of the environment record. The binding will be a mutable binding. The corresponding global object property will have attribute values approxe for a var. The String value N is the text of the bound name. V is the initial value of the binding if the optional Boolean argument D is true the binding is may be subsequently deleted. This is logically equivalent to CreateMutableBinding but it allows var declarations to receive special treatment.</td>
</tr>
<tr>
<td>CreateGlobalFunctionBinding(N, V, D)</td>
<td>Used to create and initialise global function bindings in the ObjectEnvironmentComponent of the environment record. The binding will be a mutable binding. The corresponding global object property will have attribute values approxe for a function. The String value N is the text of the bound name. If the optional Boolean argument D is true the binding is may be subsequently deleted. This is logically equivalent to CreateMutableBinding followed by a SetMutableBinding but it allows function declarations to receive special treatment.</td>
</tr>
</tbody>
</table>

The behaviour of the concrete specification methods for Global Environment Records is defined by the following algorithms.

8.1.1.4.1 HasBinding(N)

The concrete environment record method HasBinding for global environment records simply determines if the argument identifier is one of the identifiers bound by the record.
1. Let envRec be the global environment record for which the method was invoked.
2. Let DeclarativeEnvironment be envRec’s DeclarativeEnvironment.
3. If the result of calling DeclarativeEnvironment’s HasBinding concrete method with argument Name is true, return true.
4. Let ObjRec be envRec’s ObjectEnvironment.
5. Return the result of calling ObjRec’s HasBinding concrete method with argument Name.

8.1.1.4.2 CreateMutableBinding (N, D)

The concrete environment record method CreateMutableBinding for global environment records creates a new mutable binding for the name N that is uninitialised. The binding is created in the associated DeclarativeEnvironment. A binding for N must not already exist in the DeclarativeEnvironment. If Boolean argument D is provided and has the value true the new binding is marked as being subject to deletion.

1. Let envRec be the global environment record for which the method was invoked.
2. Let DeclarativeEnvironment be envRec’s DeclarativeEnvironment.
3. Assert: DeclarativeEnvironment does not already have a binding for N.
4. Return the result of calling the CreateMutableBinding concrete method of DeclarativeEnvironment with arguments N and D.

8.1.1.4.3 CreateImmutableBinding (N)

The concrete Environment Record method CreateImmutableBinding for global environment records creates a new immutable binding for the name N that is uninitialised. A binding must not already exist in this environment record for N.

1. Let envRec be the global environment record for which the method was invoked.
2. Let DeclarativeEnvironment be envRec’s DeclarativeEnvironment.
3. Assert: DeclarativeEnvironment does not already have a binding for N.
4. Return the result of calling the CreateImmutableBinding concrete method of DeclarativeEnvironment with argument N.

8.1.1.4.4 InitialiseBinding (N, V)

The concrete Environment Record method InitialiseBinding for global environment records is used to set the bound value of the current binding of the identifier whose name is the value of the argument Name to the value of argument Value. An uninitialised binding for Name must already exist.

1. Let envRec be the global environment record for which the method was invoked.
2. Let DeclarativeEnvironment be envRec’s DeclarativeEnvironment.
3. If the result of calling DeclarativeEnvironment’s HasBinding concrete method with argument Name is true, then
   a. Return the result of calling DeclarativeEnvironment’s InitialiseBinding concrete method with arguments Name and Value.
4. Assert: The binding exists it must be in the object environment record.
5. Let ObjRec be envRec’s ObjectEnvironment.
6. Return the result of calling ObjRec’s InitialiseBinding concrete method with arguments Name and Value.

8.1.1.4.5 SetMutableBinding (N, V, S)

The concrete Environment Record method SetMutableBinding for global environment records attempts to change the bound value of the current binding of the identifier whose name is the value of the argument Name to the value of argument Value. If the binding is an immutable binding, a TypeError is thrown if S is true. A property named Name normally already exists but if it does not or is not currently writable, error handling is determined by the value of the Boolean argument S.

1. Let envRec be the declarative environment record for which the method was invoked.
2. Let DeclarativeEnvironment be envRec’s DeclarativeEnvironment.
3. If the result of calling DeclarativeEnvironment’s HasBinding concrete method with argument Name is true, then
   a. Return the result of calling the SetMutableBinding concrete method of DeclarativeEnvironment with arguments Name, Value, and S.
4. Let ObjRec be envRec’s ObjectEnvironment.
5. Return the result of calling the SetMutableBinding concrete method of ObjRec with arguments Name, Value, and S.
8.1.1.4.6 GetBindingValue(N,S)

The concrete Environment Record method GetBindingValue for global environment records simply returns the value of its bound identifier whose name is the value of the argument N. If S is true and the binding is an uninitialised binding throw a ReferenceError exception. A property named N normally already exists but if it does not or is not currently writable, error handling is determined by the value of the Boolean argument S.

1. Let envRec be the declarative environment record for which the method was invoked.
2. Let DclRec be envRec’s DeclarativeEnvironment.
3. If the result of calling DclRec’s HasBinding concrete method with argument N is true, then
   a. Return the result of calling the GetBindingValue concrete method of DclRec with arguments N, and S.
4. Let ObjRec be envRec’s ObjectEnvironment.
5. Return the result of calling the GetBindingValue concrete method of ObjRec with arguments N, and S.

8.1.1.4.7 DeleteBinding (N)

The concrete Environment Record method DeleteBinding for global environment records can only delete bindings that have been explicitly designated as being subject to deletion.

1. Let envRec be the declarative environment record for which the method was invoked.
2. Let DclRec be envRec’s DeclarativeEnvironment.
3. If the result of calling DclRec’s HasBinding concrete method with argument N is true, then
   a. Return the result of calling the DeleteBinding concrete method of DclRec with argument N.
4. Let ObjRec be envRec’s ObjectEnvironment.
5. If the result of calling ObjRec’s HasBinding concrete method with argument N is true, then
   a. Let status be the result of calling the DeleteBinding concrete method of ObjRec with argument N.
   b. ReturnIfAbrupt(status).
   c. If status is true, then
      i. Let varNames be envRec’s VarNames List.
      ii. If N is an element of varNames, then remove that element from the varNames.
   d. Return status.
6. Return true.

8.1.1.4.8 HasThisBinding ()

Global Environment Records always provide a this binding whose value is the associated global object.

1. Return true.

8.1.1.4.9 HasSuperBinding ()

1. Return false.

8.1.1.4.10 WithBaseObject()

Global Environment Records always return undefined as their WithBaseObject.

1. Return undefined.

8.1.1.4.11 GetThisBinding ()

1. Let envRec be the global environment record for which the method was invoked.
2. Let ObjRec be envRec’s ObjectEnvironment.
3. Let bindings be the binding object for ObjRec.
4. Return bindings.
8.1.1.4.12 HasVarDeclaration (N)

The concrete environment record method HasVarDeclaration for global environment records determines if the argument identifier has a binding in this record that was created using a VariableStatement or a FunctionDeclaration:

1. Let envRec be the global environment record for which the method was invoked.
2. Let varDeclaredNames be envRec's VarNames List.
3. If varDeclaredNames contains the value of N, return true.
4. Return false.

8.1.1.4.13 HasLexicalDeclaration (N)

The concrete environment record method HasLexicalDeclaration for global environment records determines if the argument identifier has a binding in this record that was created using a lexical declaration such as a LexicalDeclaration or a ClassDeclaration:

1. Let envRec be the global environment record for which the method was invoked.
2. Let DclRec be envRec’s DeclarativeEnvironment.
3. Return the result of calling DclRec’s HasBinding concrete method with argument N.

8.1.1.4.14 CanDeclareGlobalVar (N)

The concrete environment record method CanDeclareGlobalVar for global environment records determines if a corresponding CreateGlobalVarBinding call would succeed if called for the same argument N. Redundant var declarations and var declarations for pre-existing global object properties are allowed.

1. Let envRec be the global environment record for which the method was invoked.
2. Let ObjRec be envRec’s ObjectEnvironment.
3. If the result of calling ObjRec’s HasBinding concrete method with argument N is true, return true.
4. Let bindings be the binding object for ObjRec.
5. Let extensible be the result of IsExtensible(bindings).
6. Return extensible.

8.1.1.4.15 CanDeclareGlobalFunction (N)

The concrete environment record method CanDeclareGlobalFunction for global environment records determines if a corresponding CreateGlobalFunctionBinding call would succeed if called for the same argument N.

1. Let envRec be the global environment record for which the method was invoked.
2. Let ObjRec be envRec’s ObjectEnvironment.
3. Let globalObject be the binding object for ObjRec.
4. Let extensible be the result of IsExtensible(globalObject).
5. ReturnIfAbrupt(extensible).
6. If the result of calling ObjRec’s HasBinding concrete method with argument N is false, then return extensible.
7. Let existingProp be the result of calling the [[GetOwnProperty]] internal method of globalObject with argument N.
8. If existingProp is undefined, then return extensible.
9. If existingProp [[Configurable]] is true, then return true.
10. If IsDataDescriptor(existingProp) is true and existingProp has attribute values { [[Writable]]: true, [[Enumerable]]: true }, then return true.
11. Return false.
8.1.1.4.16 **CreateGlobalVarBinding (N, D)**

The concrete Environment Record method CreateGlobalVarBinding for global environment records creates a mutable binding in the associated object environment record and records the bound name in the associated VarNames List. If a binding already exists, it is reused.

1. Let envRec be the declarative environment record for which the method was invoked.
2. Let ObjRec be envRec’s ObjectEnvironment.
3. If the result of calling ObjRec’s HasBinding concrete method with argument N is false, then
   a. Let status be the result of calling the CreateMutableBinding concrete method of ObjRec with arguments N and D.
   b. ReturnIfAbrupt(status).
4. Let varDeclaredNames be envRec’s VarNames List.
5. If varDeclaredNames does not contain the value of N, then
   a. Append N to varDeclaredNames.
6. Return NormalCompletion(empty).

8.1.1.4.17 **CreateGlobalFunctionBinding (N, V, D)**

The concrete Environment Record method CreateGlobalFunctionBinding for global environment records creates a mutable binding in the associated object environment record and records the bound name in the associated VarNames List. If a binding already exists, it is replaced.

1. Let envRec be the declarative environment record for which the method was invoked.
2. Let ObjRec be envRec’s ObjectEnvironment.
3. Let globalObject be the binding object for ObjRec.
4. Let existingProp be the result of calling the [[GetOwnProperty]] internal method of globalObject with argument N.
5. If existingProp is undefined or existingProp.[[Configurable]] is true, then
   a. Let desc be Property Descriptor {[[Value]]: V, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: D}.
6. Else,
   a. Let desc be Property Descriptor {[[Value]]: V}.
7. Let status be the result of DefinePropertyOrThrow(globalObject, N, desc).
8. ReturnIfAbrupt(status).
9. Let varDeclaredNames be envRec’s VarNames List.
10. If varDeclaredNames does not contain the value of N, then
    a. Append N to varDeclaredNames.
11. Return NormalCompletion(empty).

**NOTE**
Global function declarations are always represented as own properties of the global object. If possible, an existing own property is reconfigured to have a standard set of attribute values.

8.1.2 **Lexical Environment Operations**

The following abstract operations are used in this specification to operate upon lexical environments:

8.1.2.1 **GetIdentifierReference (lex, name, strict)**

The abstract operation GetIdentifierReference is called with a Lexical Environment lex, a String name, and a Boolean flag strict. The value of lex may be null. When called, the following steps are performed:

1. If lex is the value null, then
   a. Return a value of type Reference whose base value is undefined, whose referenced name is name, and whose strict reference flag is strict.
2. Let envRec be lex’s environment record.
3. Let exists be the result of calling the HasBinding(N) concrete method of envRec passing name as the argument N.
4. If exists is true, then
a. Return a value of type Reference whose base value is \textit{envRec}, whose referenced name is \textit{name}, and whose strict reference flag is \textit{strict}.

5. Else
   a. Let \textit{outer} be the value of \textit{lex}'s outer environment reference.
   b. Return the result of calling GetIdentifierReference passing \textit{outer}, \textit{name}, and \textit{strict} as arguments.

8.1.2.2 NewDeclarativeEnvironment (E)

When the abstract operation NewDeclarativeEnvironment is called with either a Lexical Environment or \textit{null} as argument \textit{E} the following steps are performed:

1. Let \textit{env} be a new Lexical Environment.
2. Let \textit{envRec} be a new declarative environment record containing no bindings.
3. Set \textit{env}'s environment record to be \textit{envRec}.
4. Set the outer lexical environment reference of \textit{env} to \textit{E}.
5. Return \textit{env}.

8.1.2.3 NewObjectEnvironment (O, E)

When the abstract operation NewObjectEnvironment is called with an Object \textit{O} and a Lexical Environment \textit{E} (or \textit{null}) as arguments, the following steps are performed:

1. Let \textit{env} be a new Lexical Environment.
2. Let \textit{envRec} be a new object environment record containing \textit{O} as the binding object.
3. Let \textit{envRec}'s unscopables be an empty List.
4. Set \textit{env}'s environment record to be \textit{envRec}.
5. Set the outer lexical environment reference of \textit{env} to \textit{E}.
6. Return \textit{env}.

8.1.2.4 NewFunctionEnvironment (F, T)

When the abstract operation NewFunctionEnvironment is called with an ECMAScript function Object \textit{F} and an ECMAScript value \textit{T} as arguments, the following steps are performed:

1. Assert: The value of \textit{F}'s [[ThisMode]] internal data property is not lexical.
2. Let \textit{env} be a new Lexical Environment.
3. Let \textit{envRec} be a new Function environment record containing containing no bindings.
4. Set \textit{envRec}'s thisValue to \textit{T}.
5. If \textit{F} has a [[HomeObject]] internal data property, then
   a. Set \textit{envRec}'s HomeObject to the value of \textit{F}'s [[HomeObject]] internal data property.
   b. Set \textit{envRec}'s MethodName to the value of \textit{F}'s [[MethodName]] internal data property.
6. Else,
   a. Set \textit{envRec}'s HomeObject to \textit{Empty}.
7. Set \textit{env}'s environment record to be \textit{envRec}.
8. Set the outer lexical environment reference of \textit{env} to the value of \textit{F}'s [[Scope]] internal data property.
9. Return \textit{env}.

8.2 Code Realms

Before it is evaluated, all ECMAScript code must be associated with a \textit{Realm}. Conceptually, a realm consists of a set of intrinsic objects, an ECMAScript global environment, all of the ECMAScript code that is loaded within the scope of that global environment, a Loader object that can associate new ECMAScript code with the realm, and other associated state and resources.

A Realm is specified as a Record with the fields specified in Table 20:

Commented [AWB812]: Other possible terms that have been discussed are ‘Home’ and ‘Island’. We still need to get final agreement on terminology.
### Table 20 — Realm Record Fields

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[[intrinsics]]</code></td>
<td>A record whose field names are intrinsic keys and whose values are objects</td>
<td>These are the intrinsic values used by code associated with this Realm</td>
</tr>
<tr>
<td><code>[[globalThis]]</code></td>
<td>An ECMAScript object</td>
<td>The global object for this Realm</td>
</tr>
<tr>
<td><code>[[globalEnv]]</code></td>
<td>A ECMAScript environment</td>
<td>The global environment for this Realm</td>
</tr>
<tr>
<td><code>[[loader]]</code></td>
<td>any ECMAScript identifier or empty</td>
<td>The Loader object that can associate ECMAScript code with this Realm</td>
</tr>
</tbody>
</table>

The intrinsic objects associated with a code Realm include the well-known intrinsics listed in Table 7 and additional intrinsics specified by Table 21.

### Table 21 — Additional Intrinsic Objects with Realm Specific Bindings

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>ECMAScript Language Association</th>
</tr>
</thead>
<tbody>
<tr>
<td>???</td>
<td>???</td>
</tr>
<tr>
<td>???</td>
<td>???</td>
</tr>
</tbody>
</table>

### 8.3 Execution Contexts

An execution context is a specification device that is used to track the runtime evaluation of code by an ECMAScript implementation. At any point in time, there is at most one execution context that is actually executing code. This is known as the running execution context. A stack is used to track execution contexts. The running execution context is always the top element of this stack. A new execution context is created whenever control is transferred from the executable code associated with the currently running execution context to executable code that is not associated with that execution context. The newly created execution context is pushed onto the stack and becomes the running execution context.

An execution context contains whatever implementation specific state is necessary to track the execution progress of its associated code. Each execution context has the state components listed in Table 22.

### Table 22 — State Components for All Execution Contexts

<table>
<thead>
<tr>
<th>Component</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>code evaluation state</td>
<td>Any state needed to perform, suspend, and resume evaluation of the code associated with this execution context.</td>
</tr>
<tr>
<td>Realm</td>
<td>The Realm from which associated code accesses ECMAScript resources.</td>
</tr>
</tbody>
</table>

Evaluation of code by the running execution context may be suspended at various points defined within this specification. Once the running execution context has been suspended a different execution context may become the running execution context and commence evaluating its code. At some latter time a suspended execution context may again become the running execution context and continue evaluating its code at the point where it had previously been suspended. Transition of the running execution context status among execution contexts usually occurs in stack-like last-in/first-out manner. However, some ECMAScript features require non-LIFO transitions of the running execution context.

The value is the Realm component of the running execution context is also called the current Realm.

Execution contexts for ECMAScript code have the additional state components listed in Table 23.
Table 23 — Additional State Components for ECMAScript Code Execution Contexts

<table>
<thead>
<tr>
<th>Component</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>LexicalEnvironment</td>
<td>Identifies the Lexical Environment used to resolve identifier references made by code within this execution context.</td>
</tr>
<tr>
<td>VariableEnvironment</td>
<td>Identifies the Lexical Environment whose environment record holds bindings created by VariableStatements within this execution context.</td>
</tr>
</tbody>
</table>

The LexicalEnvironment and VariableEnvironment components of an execution context are always Lexical Environments. When an execution context is created its LexicalEnvironment and VariableEnvironment components initially have the same value. The value of the VariableEnvironment component never changes while the value of the LexicalEnvironment component may change during execution of code within an execution context.

Execution contexts representing the evaluation of generator objects have the additional state components listed in Table 24.

Table 24 -- Additional State Components for Generator Execution Contexts

<table>
<thead>
<tr>
<th>Component</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generator</td>
<td>The GeneratorObject that this execution context is evaluating.</td>
</tr>
</tbody>
</table>

In most situations only the running execution context (the top of the execution context stack) is directly manipulated by algorithms within this specification. Hence when the terms “LexicalEnvironment”, and “VariableEnvironment” are used without qualification they are in reference to those components of the running execution context.

An execution context is purely a specification mechanism and need not correspond to any particular artefact of an ECMAScript implementation. It is impossible for an ECMAScript program to directly access or observe an execution context.

8.3.1 Identifier Resolution

Identifier resolution is the process of determining the binding of an IdentifierName using the LexicalEnvironment of the running execution context. During execution of ECMAScript code, Identifier Resolution is performed using the following algorithm:

1. Let `env` be the running execution context’s LexicalEnvironment.
2. If the syntactic production that is being evaluated is contained in strict mode code, then let `strict` be `true`, else let `strict` be `false`.
3. Return the result of calling GetIdentifierReference abstract operation passing `env`, the StringValue of `IdentifierName`, and `strict` as arguments.

The result of evaluating an identifier is always a value of type Reference with its referenced name component equal to the `IdentifierName` String.

8.3.2 GetThisEnvironment

The abstract operation GetThisEnvironment finds the lexical environment that currently supplies the binding of the keyword `this`. GetThisEnvironment performs the following steps:

1. Let `lex` be the running execution context’s LexicalEnvironment.
2. Repeat
   a. Let `envRec` be `lex`’s environment record.
   b. Let `exists` be the result of calling the HasThisBinding concrete method of `envRec`.
   c. If `exists` is `true`, then return `envRec`.
   d. Let `outer` be the value of `lex`’s outer environment reference.
e. Let lex be outer.

NOTE The loop in step 2 will always terminate because the list of environments always ends with the global environment which has a this binding.

8.3.3 ThisResolution

The abstract operation ThisResolution is the process of determining the binding of the keyword this using the LexicalEnvironment of the running execution context. ThisResolution performs the following steps:

1. Let env be the result of performing the GetThisEnvironment abstract operation.
2. Return the result of calling the GetThisBinding concrete method of env.

8.3.4 GetGlobalObject

The abstract operation GetGlobalObject returns the global object used by the currently running execution context. GetGlobalObject performs the following steps:

1. Let ctx be the running execution context.
2. Let currentRealm be ctx’sRealm.
3. Return currentRealm.[[globalThis]].

9 ECMAScript Ordinary and Exotic Objects Behaviors

9.1 Ordinary Object Internal Methods and Internal Data Properties

All ordinary objects have an internal data property called [[Prototype]]. The value of this property is either null or an object and is used for implementing inheritance. Data properties of the [[Prototype]] object are inherited (are visible as properties of the child object) for the purposes of get access, but not for set access. Accessor properties are inherited for both get access and set access.

Every ordinary ECMAScript object has a Boolean-valued [[Extensible]] internal data property that controls whether or not properties may be added to the object. If the value of the [[Extensible]] internal data property is false then additional properties may not be added to the object. In addition, if [[Extensible]] is false the value of [[Prototype]] internal data properties of the object may not be modified. Once the value of an object’s [[Extensible]] internal data property has been set to false it may not be subsequently changed to true.

In the following algorithm descriptions, assume O is an ordinary ECMAScript object, P is a property key value, V is any ECMAScript language value, and Desc is a Property Description record.

9.1.1 [[GetInheritance]] ( )

When the [[GetInheritance]] internal method of O is called the following steps are taken:

1. Return the value of the [[Prototype]] internal data property of O.

9.1.2 [[SetInheritance]] (V)

When the [[SetInheritance]] internal method of O is called with argument V the following steps are taken:

1. Assert: Either Type(V) is Object or Type(V) is Null.
2. Let extensible be the value of the [[Extensible]] internal data property of O.
3. Let current be the value of the [[Prototype]] internal data property of O.
4. If SameValue(V, current), then return true.
5. If extensible is false, then return false.
6. If V is not null, then
   a. Let p be V.
   b. Repeat, while p is not null
      i. If SameValue(p, O) is true, then return false.
ii. Let nextp be the result of calling the [[GetInheritance]] internal method of p with no arguments.
iii. ReturnIfAbrupt(nextp).
iv. Let p be nextp.
7. Set the value of the [[Prototype]] internal data property of O to V.
8. Return true.

9.1.3 [[IsExtensible]] ()
When the [[IsExtensible]] internal method of O is called, the following steps are taken:
1. Return the value of the [[Extensible]] internal data property of O.

9.1.4 [[PreventExtensions]] ()
When the [[PreventExtensions]] internal method of O is called, the following steps are taken:
1. Set the value of the [[Extensible]] internal data property of O to false.
2. Return true.

9.1.5 [[HasOwnProperty]] (P)
When the [[HasOwnProperty]] internal method of O is called with property key P, the following steps are taken:
1. Assert: IsPropertyKey(P) is true.
2. If O does not have an own property with key P, return false
3. Return true.

9.1.6 [[GetOwnProperty]] (P)
When the [[GetOwnProperty]] internal method of O is called with property key P, the following steps are taken:
1. Return the result of OrdinaryGetOwnProperty with arguments O and P.

9.1.6.1 OrdinaryGetOwnProperty (O, P)
When the abstract operation OrdinaryGetOwnProperty is called with Object O and with property key P, the following steps are taken:
1. Assert: IsPropertyKey(P) is true.
2. If O does not have an own property with key P, return undefined.
3. Let X be O’s own property whose key is P.
4. Let D be a newly created Property Descriptor with no fields.
5. If X is a data property, then
   a. Set D.[[Value]] to the value of X’s [[Value]] attribute.
   b. Set D.[[Writable]] to the value of X’s [[Writable]] attribute
6. Else X is an accessor property, so
   a. Set D.[[Get]] to the value of X’s [[Get]] attribute.
   b. Set D.[[Set]] to the value of X’s [[Set]] attribute.
7. Set D.[[Enumerable]] to the value of X’s [[Enumerable]] attribute.
8. Set D.[[Configurable]] to the value of X’s [[Configurable]] attribute.
9. Return D.

9.1.7 [[DefineOwnProperty]] (P, Desc)
When the [[DefineOwnProperty]] internal method of O is called with property key P and property descriptor Desc, the following steps are taken:
1. Return the result of OrdinaryDefineOwnProperty with arguments O, P, and Desc.
9.1.7.1 OrdinaryDefineOwnProperty (O, P, Desc)

When the abstract operation OrdinaryDefineOwnProperty is called with Object O, property key P, and property descriptor Desc the following steps are taken:

1. Let current be the result of calling OrdinaryGetOwnProperty with arguments O and P.
2. Let extensible be the value of the [[Extensible]] internal data property of O.
3. Return the result of ValidateAndApplyPropertyDescriptor with arguments O, P, extensible, Desc, and current.

9.1.7.2 IsCompatiblePropertyDescriptor (Extensible, Desc, Current)

When the abstract operation IsCompatiblePropertyDescriptor is called with Boolean value Extensible, and property descriptors Desc, and Current the following steps are taken:

1. Return the result of ValidateAndApplyPropertyDescriptor with arguments undefined, undefined, Extensible, Desc, and Current.

9.1.7.3 ValidateAndApplyPropertyDescriptor (O, P, extensible, Desc, current)

When the abstract operation ValidateAndApplyPropertyDescriptor is called with Object O, property key P, Boolean value extensible, and property descriptor Desc, and current the following steps are taken:

This algorithm contains steps that test various fields of the Property Descriptor Desc for specific values. The fields that are tested in this manner need not actually exist in Desc. If a field is absent then its value is considered to be false.

NOTE  If undefined is passed as the O argument only validation is performed and no object updates are performed.

1. Assert: If O is not undefined then P is a valid property key.
2. If current is undefined, then
   a. If extensible is false, then return false.
   b. Assert: extensible is true.
   c. If IsGenericDescriptor(Desc) or IsDataDescriptor(Desc) is true, then
      i. If O is not undefined, then create an own data property named P of object O whose [[Value]], [[Writable]], [[Enumerable]] and [[Configurable]] attribute values are described by Desc. If the value of an attribute field of Desc is absent, the attribute of the newly created property is set to its default value.
   d. Else Desc must be an accessor Property Descriptor,
      i. If O is not undefined, then create an own accessor property named P of object O whose [[Get]], [[Set]], [[Enumerable]] and [[Configurable]] attribute values are described by Desc. If the value of an attribute field of Desc is absent, the attribute of the newly created property is set to its default value.
   e. Return true.
3. Return true, if every field in Desc is absent.
4. Return true, if every field in Desc also occurs in current and the value of every field in Desc is the same value as the corresponding field in current when compared using the SameValue algorithm.
5. If the [[Configurable]] field of current is false then
   a. Return false, if the [[Configurable]] field of Desc is true.
   b. Return false, if the [[Enumerable]] field of Desc is present and the [[Enumerable]] fields of current and Desc are the Boolean negation of each other.
6. If IsGenericDescriptor(Desc) is true, then no further validation is required.
7. Else if IsDataDescriptor(current) and IsDataDescriptor(Desc) have different results, then
   a. Return false, if the [[Configurable]] field of current is false.
   b. If IsDataDescriptor(current) is true, then
      i. If O is not undefined, then convert the property named P of object O from a data property to an accessor property. Preserve the existing values of the converted property’s [[Configurable]] and [[Enumerable]] attributes and set the rest of the property’s attributes to their default values.
   c. Else,
i. If \( O \) is not \texttt{undefined}, then convert the property named \( P \) of object \( O \) from an accessor property to a data property. Preserve the existing values of the converted property’s \([\text{[Configurable]}]\) and \([\text{[Enumerable]}]\) attributes and set the rest of the property’s attributes to their default values.

8. Else if \( \text{IsDataDescriptor}(\text{current}) \) and \( \text{IsDataDescriptor}(\text{Desc}) \) are both \texttt{true}, then
   a. If the \([\text{[Configurable]}]\) field of \( \text{current} \) is \texttt{false}, then
      i. \text{Return} \texttt{false}, if the \([\text{[Writable]}]\) field of \( \text{current} \) is \texttt{false} and the \([\text{[Writable]}]\) field of \( \text{Desc} \) is \texttt{true}.
      ii. If the \([\text{[Writable]}]\) field of \( \text{current} \) is \texttt{false}, then
           1. \text{Return} \texttt{false}, if the \([\text{[Value]}]\) field of \( \text{Desc} \) is present and \( \text{SameValue}(\text{Desc}.[\text{[Value]}], \text{current}.[\text{[Value]}]) \) is \texttt{false}.
   b. Else the \([\text{[Configurable]}]\) field of \( \text{current} \) is \texttt{true}, so any change is acceptable.

9. Else \( \text{IsAccessorDescriptor}(\text{current}) \) and \( \text{IsAccessorDescriptor}(\text{Desc}) \) are both \texttt{true}.
   a. If the \([\text{[Configurable]}]\) field of \( \text{current} \) is \texttt{false}, then
      i. \text{Return} \texttt{false}, if the \([\text{[Set]}]\) field of \( \text{Desc} \) is present and \( \text{SameValue}(\text{Desc}.[\text{[Set]}], \text{current}.[\text{[Set]]}) \) is \texttt{false}.
      ii. \text{Return} \texttt{false}, if the \([\text{[Get]}]\) field of \( \text{Desc} \) is present and \( \text{SameValue}(\text{Desc}.[\text{[Get]}], \text{current}.[\text{[Get]]}) \) is \texttt{false}.

10. If \( O \) is not \texttt{undefined}, then
    a. For each attribute field of \( \text{Desc} \) that is present, set the correspondingly named attribute of the property named \( P \) of object \( O \) to the value of the field.

11. \text{Return} \texttt{true}.

\textbf{NOTE} Step 8.b allows any field of \( \text{Desc} \) to be different from the corresponding field of \( \text{current} \) if \( \text{current}'s \) \([\text{[Configurable]}]\) field is \texttt{true}. This even permits changing the \([\text{[Value]}]\) of a property whose \([\text{[Writable]}]\) attribute is \texttt{false}. This is allowed because a \texttt{true} \([\text{[Configurable]}]\) attribute would permit an equivalent sequence of calls where \([\text{[Writable]}]\) is first set to \texttt{true}, a new \([\text{[Value]}]\) is set, and then \([\text{[Writable]}]\) is set to \texttt{false}.

\textbf{9.1.8 \([\text{HasProperty}](\text{current})\)(\text{P})}

When the \([\text{HasProperty}]\) internal method of \( O \) is called with property key \( P \), the following steps are taken:

1. \text{Assert: IsPropertyKey}(P) is \texttt{true}.
2. \text{Let hasOwn be the result of calling the \([\text{HasOwnProperty}]\) internal method of \( O \) with argument \( P \).}
3. \text{ReturnIfAbrupt(hasOwn).}
4. If hasOwn is \texttt{false}, then
   a. Let parent be the result of calling the \([\text{GetInheritance}]\) internal method of \( O \).
   b. \text{ReturnIfAbrupt(parent).}
   c. If parent is \texttt{null}, then \text{return undefined.}
   d. Return the result of calling the \([\text{HasProperty}]\) internal method of parent with argument \( P \).
5. \text{Return hasOwn.}

\textbf{9.1.9 \([\text{Get}]\)(\text{P}, \text{Receiver})}

When the \([\text{Get}]\) internal method of \( O \) is called with property key \( P \) and ECMAScript language value \( \text{Receiver} \) the following steps are taken:

1. \text{Assert: IsPropertyKey}(P) is \texttt{true}.
2. \text{Let desc be the result of calling the \([\text{GetOwnProperty}]\) internal method of \( O \) with argument \( P \).}
3. \text{ReturnIfAbrupt(desc).}
4. If desc is \texttt{undefined}, then
   a. Let parent be the result of calling the \([\text{GetInheritance}]\) internal method of \( O \).
   b. \text{ReturnIfAbrupt(parent).}
   c. If parent is \texttt{null}, then \text{return undefined.}
   d. Return the result of calling the \([\text{Get}]\) internal method of parent with arguments \( P \) and \( \text{Receiver} \).
5. If \( \text{IsDataDescriptor}(\text{desc}) \) is \texttt{true}, return desc.\([\text{[Value]}]\).
6. Otherwise, \( \text{IsAccessorDescriptor}(\text{desc}) \) must be \texttt{true} so, let \( \text{getter be desc.}[\text{[Get]}] \).
7. If \( \text{getter} \) is \texttt{undefined}, return \text{undefined.}
8. Return the result of calling the \([\text{Call}]\) internal method of \( \text{getter} \) with \( \text{Receiver} \) as the \text{thisArgument} and an empty List as \text{argumentsList}. 
9.1.10 \(\text{[[Set]]} (P, V, \text{Receiver})\)

When the \(\text{[[Set]]}\) internal method of \(O\) is called with property key \(P\), value \(V\), and ECMAScript language value \(\text{Receiver}\), the following steps are taken:

1. Assert: \(\text{IsPropertyKey}(P)\) is true.
2. Let \(\text{ownDesc}\) be the result of calling the \(\text{[[GetOwnProperty]]}\) internal method of \(O\) with argument \(P\).
3. ReturnIfAbrupt(\(\text{ownDesc}\)).
4. If \(\text{ownDesc}\) is undefined, then
   a. Let \(\text{parent}\) be the result of calling the \(\text{[[GetInheritance]]}\) internal method of \(O\).
   b. ReturnIfAbrupt(\(\text{parent}\)).
   c. If \(\text{parent}\) is not null, then
      i. Return the result of calling the \(\text{[[Set]]}\) internal method of \(\text{parent}\) with arguments \(P\), \(V\), and \(\text{Receiver}\).
   d. Else
      i. Let \(\text{ownDesc}\) be the Property Descriptor \(\{\text{[[Value]]}: \text{undefined}, \text{[[Writable]]}: \text{true}, \text{[[Enumerable]]}: \text{true}, \text{[[Configurable]]}: \text{true}\}\).
5. If \(\text{IsDataDescriptor}(\text{ownDesc})\) is true, then
   a. If \(\text{ownDesc}.\text{[[Writable]]}\) is false, return false.
   b. If \(\text{Type}(\text{Receiver})\) is not Object, return false.
   c. Let \(\text{existingDescriptor}\) be the result of calling the \(\text{[[GetOwnProperty]]}\) internal method of \(\text{Receiver}\) with argument \(P\).
   d. ReturnIfAbrupt(\(\text{existingDescriptor}\)).
   e. If \(\text{existingDescriptor}\) is not undefined, then
      i. Let \(\text{valueDesc}\) be the Property Descriptor \(\{\text{[[Value]]}: V\}\).
      ii. Return the result of calling the \(\text{[[DefineOwnProperty]]}\) internal method of \(\text{Receiver}\) with arguments \(P\) and \(\text{valueDesc}\).
   f. Else \(\text{Receiver}\) does not currently have a property \(P\),
      i. Return the result of performing \(\text{CreateOwnProperty}(\text{Receiver}, P, V)\).
5. If \(\text{IsAccessorDescriptor}(\text{ownDesc})\) is true, then
   a. Let \(\text{setter}\) be \(\text{ownDesc}.\text{[[Set]]}\).
   b. If \(\text{setter}\) is undefined, return false.
   c. Let \(\text{setterResult}\) be the result of calling the \(\text{[[Call]]}\) internal method of \(\text{setter}\) providing \(\text{Receiver}\) as this Argument and a new List containing \(V\) as argumentsList.
   d. ReturnIfAbrupt(\(\text{setterResult}\)).
   e. Return true.

9.1.11 \(\text{[[Invoke]]} (P, \text{ArgumentsList}, \text{Receiver})\)

When the \(\text{[[Invoke]]}\) internal method of \(O\) is called with property key \(P\), List \(\text{ArgumentsList}\), and ECMAScript language value \(\text{Receiver}\) the following steps are taken:

1. Assert: \(\text{IsPropertyKey}(P)\) is true.
2. Assert: \(\text{ArgumentsList}\) is a List.
3. Let \(\text{method}\) be the result of calling the \(\text{[[Get]]}\) internal method of \(O\) with arguments \(P\), and \(\text{Receiver}\).
4. ReturnIfAbrupt(\(\text{method}\)).
5. If \(\text{Type}(\text{method})\) is not Object, throw a \text{TypeError} exception.
6. If \(\text{IsCallable}(\text{method})\) is false, throw a \text{TypeError} exception.
7. Return the result of calling the \(\text{[[Call]]}\) internal method of \(\text{method}\) with \(\text{Receiver}\) as the \(\text{thisArgument}\) and \(\text{ArgumentsList}\) as argumentsList.

9.1.12 \(\text{[[Delete]]} (P)\)

When the \(\text{[[Delete]]}\) internal method of \(O\) is called with property key \(P\) the following steps are taken:

1. Assert: \(\text{IsPropertyKey}(P)\) is true.
2. Let \(\text{desc}\) be the result of calling the \(\text{[[GetOwnProperty]]}\) internal method of \(O\) with argument \(P\).
3. If \(\text{desc}\) is undefined, then return true.
4. If \(\text{desc}.\text{[[Configurable]]}\) is true, then
   a. Remove the own property with name \(P\) from \(O\).
b. Return true.
5. Return false.

9.1.13 \[\text{[[Enumerate]]}()\]

When the \[\text{[[Enumerate]]}\] internal method of \(O\) is called the following steps are taken:

1. Return an Iterator object (25.1.2) whose next method iterates over all the String valued keys of enumerable property keys of \(O\). The mechanics and order of enumerating the properties is not specified but must conform to the rules specified below.

Enumerated properties do not include properties whose property key is a Symbol. Properties of the object being enumerated may be deleted during enumeration. If a property that has not yet been visited during enumeration is deleted, then it will not be visited. If new properties are added to the object being enumerated during enumeration, the newly added properties are not guaranteed to be visited in the active enumeration. A property name must not be visited more than once in any enumeration.

Enumerating the properties of an object includes enumerating properties of its prototype, and the prototype of the prototype, and so on, recursively; but a property of a prototype is not enumerated if it is “shadowed” because some previous object in the prototype chain has a property with the same name. The values of [[Enumerable]] attributes are not considered when determining if a property of a prototype object is shadowed by a previous object on the prototype chain.

The following is an informative algorithm that conforms to these rules:

1. Let \(obj\) be \(O\).
2. Let \(proto\) be the result of calling the \[\text{[[GetInheritance]]}\] internal method of \(O\) with no arguments.
3. ReturnIfAbrupt(proto).
4. If \(proto\) is the value null, then
   a. Let \(propList\) be a new empty List.
5. Else
   a. Let \(propList\) be the result of calling the \[\text{[[Enumerate]]}\] internal method of \(proto\).
6. ReturnIfAbrupt(propList).
7. For each \(name\) that is the property key of an own property of \(O\)
   a. If Type(\(name\)) is String, then
      i. Let \(desc\) be the result of calling OrdinaryGetOwnProperty with arguments \(O\) and \(name\).
      ii. If \(name\) is an element of \(propList\), then remove \(name\) as an element of \(propList\).
      iii. If desc.\[\text{[[Enumerable]]}\] is true, then add \(name\) as an element of \(propList\).
8. Order the elements of \(propList\) in an implementation defined order.
9. Return \(propList\).

9.1.14 \[\text{[[OwnPropertyKeys]]}()\]

When the \[\text{[[OwnPropertyKeys]]}\] internal method of \(O\) is called the following steps are taken:

1. Let \(keys\) be a new empty List.
2. For each own property key \(P\) of \(O\)
   a. Add \(P\) as the last element of \(keys\).
3. Return \(\text{MakeListIterator}(keys)\).

9.1.15 ObjectCreate(proto, internalDataList) Abstract Operation

The abstract operation ObjectCreate with argument \(proto\) (an object or null) is used to specify the runtime creation of new ordinary objects. The optional argument \(\text{internalDataList}\) is a List of the names of internal data property names that should be defined as part of the object. If the list is not provided, an empty List is used. If no arguments are provided \(\%\text{ObjectPrototype}\%\) is used as the value of \(proto\). This abstract operation performs the following steps:

1. If \(\text{internalDataList}\) was not provided, let \(\text{internalDataList}\) be an empty List.
2. Let \( \text{obj} \) be a newly created ECMAScript object with an internal data property for each name in \( \text{internalDataList} \).
3. Set \( \text{obj} \)'s essential internal methods to the default ordinary object definitions specified in 9.1.
4. Set the [[Prototype]] internal data property of \( \text{obj} \) to \( \text{proto} \).
5. Set the [[Extensible]] internal data property of \( \text{obj} \) to \text{true}.
6. Return \( \text{obj} \).

### 9.1.16 Ordinary Function Objects

Ordinary function objects encapsulate parameterised ECMAScript code closed over a lexical environment and support the dynamic evaluation of that code. An ordinary function object is an ordinary object and has the same internal data properties and (except as noted below) the same internal methods as other ordinary objects.

Ordinary function objects have the additional internal data properties listed in Table 25.

Ordinary function objects provide alternative definitions for the [[Get]] and [[GetOwnProperty]] internal methods. These alternatives prevent the value of strict mode function from being revealed as the value of a function object property named "caller". These alternative definitions exist solely to preclude a non-standard legacy feature of some ECMAScript implementations from revealing information about strict mode callers. An implementation does not provide such a feature, it need not implement these alternative internal methods for ordinary function objects.

#### Table 25 – Internal Data Properties of Ordinary Function Objects

<table>
<thead>
<tr>
<th>Internal Data Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Scope]]</td>
<td>Lexical Environment</td>
<td>The Lexical Environment that the function was closed over. Is used as the outer environment when evaluating the code of the function.</td>
</tr>
<tr>
<td>[[FormalParameters]]</td>
<td>Parse Node</td>
<td>The root parse node of the source code that defines the function's formal parameter list.</td>
</tr>
<tr>
<td>[[FunctionKind]]</td>
<td>String</td>
<td>Either &quot;normal&quot; or &quot;generator&quot;.</td>
</tr>
<tr>
<td>[[Code]]</td>
<td>Parse Node</td>
<td>The root parse node of the source code that defines the function's body.</td>
</tr>
<tr>
<td>[[Realm]]</td>
<td>Realm Record</td>
<td>The Code Realm in which the function was created and which provides any intrinsic objects that are accessed when evaluating the function.</td>
</tr>
<tr>
<td>[[ThisMode]]</td>
<td>(lexical, strict, global)</td>
<td>Defines how this references are interpreted within the formal parameters and code body of the function. <strong>lexical</strong> means that this refers to the this value of a lexically enclosing function. <strong>strict</strong> means that the this value is used exactly as provided by an invocation of the function. <strong>global</strong> means that this a this value of undefined is interpreted as a reference to the global object.</td>
</tr>
<tr>
<td>[[Strict]]</td>
<td>Boolean</td>
<td>true if this is a strict mode function, false if this is not a strict mode function.</td>
</tr>
<tr>
<td>[[HomeObject]]</td>
<td>Object</td>
<td>If the function uses super, this is the object whose [[GetInheritance]] provides the object where super property lookups begin. Not present for functions that don’t reference super.</td>
</tr>
<tr>
<td>[[MethodName]]</td>
<td>String or Symbol</td>
<td>If the function uses super, this is the property keys that is used for unqualified references to super. Not present for functions that don’t reference super.</td>
</tr>
</tbody>
</table>

Ordinary function objects all have the [[Call]], [[Get]], and [[GetOwnProperty]] internal methods defined here. Ordinary functions that are also constructors in addition have the [[Construct]] internal method.
9.1.16.1 \f{\text{Call}} (\text{thisArgument}, \text{argumentsList})

The \f{\text{Call}} internal method for an ordinary Function object \( F \) is called with parameters \text{thisArgument} and \text{argumentsList}, a List of ECMAScript language values. The following steps are taken:

1. If \( F \)'s [[Code]] internal data property has the value \text{undefined}, then throw a \text{TypeError} exception.
2. Let \text{calleeContext} be the running execution context.
3. If, \text{calleeContext} is not already suspended, then Suspend \text{calleeContext}.
4. Let \text{calleeContext} be a new ECMAScript Code execution context.
5. Let \text{calleeRealm} be the value of \( F \)'s [[Realm]] internal data property.
6. Set \text{calleeContext}'s Realm to \text{calleeRealm}.
7. Let \text{thisMode} be the value of \( F \)'s [[ThisMode]] internal data property.
8. If \text{thisMode} is \text{strict}, then
   a. Let \text{localEnv} be the result of calling NewDeclarativeEnvironment passing the value of the [[Scope]] internal data property of \( F \) as the argument.
9. Else,
   a. If \text{thisMode} is \text{true}, set \text{thisValue} to \text{thisArgument}.
   b. Else
      i. If \text{thisArgument} is \text{null} or \text{undefined}, then
         1. Set \text{thisValue} to callerContext.[[globalThis]].
         ii. Else if Type(\text{thisArgument}) is not Object, set the \text{thisValue} to ToObject(\text{thisArgument}).
         iii. Else set the \text{thisValue} to \text{thisArgument}.
   c. Let \text{localEnv} be the result of calling NewFunctionEnvironment passing \( F \) and \text{thisValue} as the arguments.
10. Set the LexicalEnvironment of \text{calleeContext} to \text{localEnv}.
11. Set the VariableEnvironment of \text{calleeContext} to \text{localEnv}.
12. Push \text{calleeContext} onto the execution context stack, \text{calleeContext} is now the running execution context.
13. Let \text{status} be the result of performing Function Declaration Instantiation using the function \( F \), \text{argumentsList} , and \text{localEnv} as described in 9.1.16.11.
14. If \text{status} is an abrupt completion, then
   a. Remove \text{calleeContext} from the execution context stack and restore \text{calleeContext} as the running execution context.
   b. Return \text{status}.
15. Let \text{result} be the result of EvaluateBody of the production that is the value of \( F \)'s [[Code]] internal data property passing \( F \) as the argument.
16. Remove \text{calleeContext} from the execution context stack and restore \text{calleeContext} as the running execution context.
17. Return \text{result}.

\text{NOTE 1} Most ordinary functions use a Function Environment Record as their LexicalEnvironment. Ordinary functions that are arrow functions use a Declarative Environment Record as their LexicalEnvironment.

\text{NOTE 2} When \text{calleeContext} is removed from the execution context stack it must not be destroyed because it may have been suspended and retained by a generator object for later resumption.

9.1.16.2 \f{\text{Construct}} (\text{argumentsList})

The \f{\text{Construct}} internal method for an ordinary Function object \( F \) is called with a single parameter \text{argumentsList} which is a possibly empty List of ECMAScript language values. The following steps are taken:

1. Return the result of OrdinaryConstruct(\( F \), \text{argumentsList}).

9.1.16.2.1 OrdinaryConstruct(\( F \), \text{argumentsList})

When the abstract operation OrdinaryConstruct is called with Object \( F \) and List \text{argumentsList} the following steps are taken:

1. Let \text{creator} be the result of Get(\( F \), @@create).
2. ReturnIfAbrupt(\text{creator}).
3. If \text{creator} is not \text{undefined}, then
   a. If IsCallable(\text{creator}) is \text{false}, then throw a \text{TypeError} exception.
b. Let obj be the result of calling the [[Call]] internal method of creator with arguments F and an empty List.

4. Else creator is undefined so fall back to object creation defaults
   a. Let obj be the result of calling OrdinaryCreateFromConstructor(F, "%ObjectPrototype%")

5. ReturnIfAbrupt(obj).

6. If Type(obj) is not Object, then throw a TypeError exception.

7. Let result be the result of calling the [[Call]] internal method of F, providing obj and argumentsList as the arguments.

8. ReturnIfAbrupt(result).

9. If Type(result) is Object then return result.

10. Return obj.

9.1.16.3 [[Get]] (P, Receiver)

When the [[Get]] internal method of ordinary function object F is called with property key P and ECMAScript language value Receiver the following steps are taken:

1. Let v be the result of calling the default ordinary object [[Get]] internal method (9.1.9) on F passing P and Receiver as arguments.

2. ReturnIfAbrupt(v).

3. If P is "caller" and v is a strict mode Function object, return null.

4. Return v.

If an implementation does not provide such a built-in caller method for function.prototype then it must not use this definition. Instead the ordinary object [[Get]] internal method is used.

9.1.16.4 [[GetOwnProperty]] (P)

When the [[GetOwnProperty]] internal method of ordinary function object F is called with property key P, the following steps are taken:

1. Let v be the result of calling the default ordinary object [[GetOwnProperty]] internal method (9.1.9) on F passing P as the argument.

2. ReturnIfAbrupt(v).

3. If IsDataDescriptor(v) is true, then
   a. If P is "caller" and v.[[Value]] is a strict mode Function object, then
      i. Set v.[[Value]] to null.

4. Return v.

If an implementation does not provide such a built-in caller method for function.prototype then it must not use this definition. Instead the ordinary object [[GetOwnProperty]] internal method is used.

9.1.16.5 FunctionAllocate Abstract Operation

The abstract operation FunctionAllocate requires the one argument, functionPrototype and accepts one optional argument, functionKind. FunctionAllocate performs the following steps:

1. Assert: Type(functionPrototype) is Object.

2. Assert: If functionKind is present, its value is either "normal" or "generator".

3. If functionKind is not present, then let functionKind be "normal".

4. Let F be a newly created ordinary function object with the internal data properties listed in Table 25. All of those internal data properties are initialized to undefined.

5. Set F’s essential internal methods except for [[Get]] and [[GetOwnProperty]] to the default ordinary object definitions specified in 9.1.

6. Set F’s essential internal methods for [[Call]], [[Get]] and [[GetOwnProperty]] to the default ordinary object definitions specified in 9.1.16.

7. Set the [[FunctionKind]] internal data property of F to functionKind.

8. Set the [[Prototype]] internal data property of F to functionPrototype.

9. Set the [[Extensible]] internal data property of F to true.

10. Set the [[Realm]] internal data property of F to the running execution context’s Realm.

11. Return F.
9.1.16.6 FunctionInitialise Abstract Operation

The abstract operation FunctionInitialise requires the arguments: a function object \( F \), \( \text{kind} \) which is one of (Normal, Method, Arrow), an parameter list production specified by \( \text{ParameterList} \), a body production specified by \( \text{Body} \), a Lexical Environment specified by \( \text{Scope} \), a Boolean flag \( \text{Strict} \), and optionally, an object \( \text{homeObject} \) and a property key \( \text{methodName} \). FunctionInitialise performs the following steps:

1. Let \( \text{len} \) be the ExpectedArgumentCount of \( \text{ParameterList} \).
2. Let \( \text{status} \) be the result of DefinePropertyOrThrow(\( F \), "\text{length}"), Property Descriptor {\( \text{[[Value]]} \): \( \text{len} \), \( \text{[[Writable]]} \): \( \text{false} \), \( \text{[[Enumerable]]} \): \( \text{false} \), \( \text{[[Configurable]]} \): \( \text{true} \)}.
3. If \( \text{Strict} \) is \text{true}, then
   a. Let \( \text{status} \) be the result of the AddRestrictedFunctionProperties abstract operation with argument \( F \).
4. b. ReturnIfAbrupt(\( \text{status} \)).
5. Set the {\( \text{[[Scope]]} \)} internal data property of \( F \) to the value of \( \text{Scope} \).
6. Set the {\( \text{[[Code]]} \)} internal data property of \( F \) to \( \text{Body} \).
7. If the \( \text{homeObject} \) argument was provided, set the {\( \text{[[HomeObject]]} \)} internal data property of \( F \) to \( \text{homeObject} \).
8. If the \( \text{methodName} \) argument was provided, set the {\( \text{[[MethodName]]} \)} internal data property of \( F \) to \( \text{methodName} \).
9. Set the {\( \text{[[Strict]]} \)} internal data property of \( F \) to \( \text{Strict} \).
10. If \( \text{kind} \) is \text{Arrow}, then set the {\( \text{[[ThisMode]]} \)} internal data property of \( F \) to \( \text{lexical} \).
11. Else if \( \text{Strict} \) is \text{true}, then set the {\( \text{[[ThisMode]]} \)} internal data property of \( F \) to \( \text{strict} \).
12. Else set the {\( \text{[[ThisMode]]} \)} internal data property of \( F \) to \( \text{global} \).
13. Return \( F \).

9.1.16.7 FunctionCreate Abstract Operation

The abstract operation FunctionCreate requires the arguments: \( \text{kind} \) which is one of (Normal, Method, Arrow), an parameter list production specified by \( \text{ParameterList} \), a body production specified by \( \text{Body} \), a Lexical Environment specified by \( \text{Scope} \), a Boolean flag \( \text{Strict} \), and optionally, an object \( \text{functionPrototype} \), an object \( \text{homeObject} \) and a property key \( \text{methodName} \). FunctionCreate performs the following steps:

1. If the \( \text{functionPrototype} \) argument was not passed, then
   a. Let \( \text{functionPrototype} \) be the intrinsic object \%FunctionPrototype\%.
2. Let \( F \) be the result of performing FunctionAllocate with argument \( \text{functionPrototype} \).
3. Return the result of performing FunctionInitialise with passing \( F \), \( \text{kind} \), \( \text{ParameterList} \), \( \text{Body} \), \( \text{Scope} \), and \( \text{Strict} \). Also pass \( \text{homeObject} \) and \( \text{methodName} \) if they are present.

9.1.16.8 GeneratorFunctionCreate Abstract Operation

The abstract operation GeneratorFunctionCreate requires the arguments: \( \text{kind} \) which is one of (Normal, Method, Arrow), an parameter list production specified by \( \text{ParameterList} \), a body production specified by \( \text{Body} \), a Lexical Environment specified by \( \text{Scope} \), a Boolean flag \( \text{Strict} \), and optionally, an object \( \text{functionPrototype} \), an object \( \text{homeObject} \) and a property key \( \text{methodName} \). GeneratorFunctionCreate performs the following steps:

1. If the \( \text{functionPrototype} \) argument was not passed, then
   a. Let \( \text{functionPrototype} \) be the intrinsic object \%Generator\%.
2. Let \( F \) be the result of performing FunctionAllocate with arguments \( \text{functionPrototype} \) and "\text{generator}".
3. Return the result of performing FunctionInitialise with passing \( F \), \( \text{kind} \), \( \text{ParameterList} \), \( \text{Body} \), \( \text{Scope} \), and \( \text{Strict} \). Also pass \( \text{homeObject} \) and \( \text{methodName} \) if they are present.

9.1.16.9 AddRestrictedFunctionProperties Abstract Operation

The abstract operation is called with a function object \( F \) as its argument. It performs the following steps:

1. Let \( \text{thrower} \) be the \%ThrowTypeError\% intrinsic function Object.
2. Let \( \text{status} \) be the result of DefinePropertyOrThrow(\( F \), "\text{caller}"), Property Descriptor {\( \text{[[Get]]} \): \( \text{thrower} \), \( \text{[[Set]]} \): \( \text{thrower} \), \( \text{[[Enumerable]]} \): \( \text{false} \), \( \text{[[Configurable]]} \): \( \text{false} \)}.
3. ReturnIfAbrupt(\( \text{status} \)).
4. Return the result of DefinePropertyOrThrow(F, "arguments", PropertyDescriptor {[[Get]]: thrower, [[Set]]: thrower, [[Enumerable]]: false, [[Configurable]]: false}).

The %ThrowTypeError% object is a unique function object that is defined once for each Realm as follows:

1. Assert: %FunctionPrototype% for the current Realm has already been initialized.
2. Let functionPrototype be the intrinsic object %FunctionPrototype%.
3. Let scope be the Global Environment.
4. Let formalParameters be the syntactic production: FormalParameters 1:empty).
5. Let body be the syntactic production: FunctionBody : ThrowTypeError.
6. Let F be the result of performing FunctionAllocate with argument functionPrototype.
7. Let %ThrowTypeError% be F.
8. Perform the abstract operation FunctionInitialise with arguments F, Normal, formalParameters, body, scope, and true.
9. Call the [[PreventExtensions]] internal method of F.

9.1.16.10 MakeConstructor Abstract Operation

The abstract operation MakeConstructor requires a Function argument F and optionally, a Boolean writablePrototype and an object prototype. If prototype is provided, it is assumed to already contain, if needed, a "constructor" property whose value is F. This operation converts F into a constructor by performing the following steps:

1. Assert: F is a ordinary function object, that has not already had MakeConstructor applied to it. It is extensible and does not have a "constructor" or a "prototype" own property.
2. Let installNeeded be false.
3. If the prototype argument was not provided, then
   a. Let installNeeded be true.
   b. Let prototype be the result of the abstract operation ObjectCreate with the intrinsic object %ObjectPrototype% as its argument.
4. If the writablePrototype argument was not provided, then
   a. Let writablePrototype be true.
5. Set F's essential internal method [[Construct]] to the definition specified in 9.1.16.2.
6. If installNeeded, then
   a. Call the [[DefineOwnProperty]] internal method of prototype with arguments "constructor" and Property Descriptor {[[Value]]: F, [[Writable]]: writablePrototype, [[Enumerable]]: false, [[Configurable]]: writablePrototype}.
   b. Call the [[DefineOwnProperty]] internal method of F with arguments "prototype" and Property Descriptor {[[Value]]: prototype, [[Writable]]: writablePrototype, [[Enumerable]]: false, [[Configurable]]: false}.
7. Return.

9.1.16.11 Function Declaration Instantiation

This version reflects the consensus as of the Sept. 2012 TC39 meeting. However, it now appears that the binding semantics of formal parameters is like to change again.

NOTE When an execution context is established for evaluating function code a new Declarative Environment Record is created and bindings for each formal parameter, and each function level variable, constant, or function declared in the function are instantiated in the environment record. Formal parameters and functions are initialised as part of this process. All other bindings are initialised during execution of the function code.

Function Declaration Instantiation is performed as follows using arguments func, argumentsList, and env. func is the function object that for which the execution context is being established. env is the declarative environment record in which bindings are to be created.
1. Let \( \text{code} \) be the value of the \([\text{Code}]\) internal data property of \( \text{func} \).
2. Let \( \text{strict} \) be the value of the \([\text{Strict}]\) internal data property of \( \text{func} \).
3. Let \( \text{formals} \) be the value of the \([\text{FormalParameters}]\) internal data property of \( \text{func} \).
4. Let \( \text{parameterNames} \) be the \( \text{BoundNames} \) of \( \text{formals} \).
5. Let \( \text{varDeclarations} \) be the \( \text{VarScopedDeclarations} \) of \( \text{code} \).
6. Let \( \text{functionsToInitialise} \) be an empty List.
7. If the value of the \([\text{ThisMode}]\) internal data property of \( \text{func} \) is \text{lexical}, then
   a. Let \( \text{argumentsObjectNeeded} \) be \text{false}.
8. Else, let \( \text{argumentsObjectNeeded} \) be \text{true}.
9. For each \( d \) in \( \text{varDeclarations} \), in reverse list order do
   a. If \( d \) is a \( \text{FunctionDeclaration} \) then
      i. NOTE: If there are multiple \( \text{FunctionDeclarations} \) for the same name, the last declaration is used.
      ii. Let \( \text{fn} \) be the sole element of the \( \text{BoundNames} \) of \( d \).
      iii. If \( \text{fn} \) is \text{"arguments"}, then let \( \text{argumentsObjectNeeded} \) be \text{false}.
      iv. Let \( \text{alreadyDeclared} \) be the result of calling \( \text{env} \)'s \text{HasBinding} concrete method passing \( \text{fn} \) as the argument.
      v. If \( \text{alreadyDeclared} \) is \text{false}, then
         1. Let \( \text{status} \) be the result of calling \( \text{env} \)'s \text{CreateMutableBinding} concrete method passing \( \text{fn} \) as the argument.
         2. Assert: \( \text{status} \) is never an abrupt completion.
   3. Append \( d \) to \( \text{functionsToInitialise} \).
10. For each String \( \text{paramName} \) in \( \text{parameterNames} \), do
    a. Let \( \text{alreadyDeclared} \) be the result of calling \( \text{env} \)'s \text{HasBinding} concrete method passing \( \text{paramName} \) as the argument.
    b. NOTE: Duplicate parameter names can only occur in non-strict functions. Parameter names that are the same as function declaration names do not get initialsed to \text{undefined}.
    c. If \( \text{alreadyDeclared} \) is \text{false}, then
       i. If \( \text{paramName} \) is \text{"arguments"}, then let \( \text{argumentsObjectNeeded} \) be \text{false}.
       ii. Let \( \text{status} \) be the result of calling \( \text{env} \)'s \text{CreateMutableBinding} concrete method passing \( \text{paramName} \) as the argument.
       iii. Assert: \( \text{status} \) is never an abrupt completion.
       iv. Call \( \text{env} \)'s \text{InitialiseBinding} concrete method passing \( \text{paramName} \) and \text{undefined} as the arguments.
11. NOTE: If there is a function declaration or formal parameter with the name \text{"arguments"} then an argument object is not created.
12. If \( \text{argumentsObjectNeeded} \) is \text{true}, then
    a. If \( \text{strict} \) is \text{true}, then
       i. Call \( \text{env} \)'s \text{CreateImmutableBinding} concrete method passing the String \text{"arguments"} as the argument.
    b. Else,
       i. Let \( \text{status} \) be the result of calling \( \text{env} \)'s \text{CreateMutableBinding} concrete method passing the String \text{"arguments"} as the argument.
       ii. Assert: \( \text{status} \) is never an abrupt completion.
13. Let \( \text{varNames} \) be the \( \text{VarDeclaredNames} \) of \( \text{code} \).
14. For each String \( \text{varName} \) in \( \text{varNames} \), in list order do
    a. Let \( \text{alreadyDeclared} \) be the result of calling \( \text{env} \)'s \text{HasBinding} concrete method passing \( \text{varName} \) as the argument.
    b. NOTE: A \( \text{VarDeclaredNames} \) is only instantiated and initialsed here if it is not also the name of a formal parameter or a \( \text{FunctionDeclarations} \).
    c. If \( \text{alreadyDeclared} \) is \text{false}, then
       i. Let \( \text{status} \) be the result of calling \( \text{env} \)'s \text{CreateMutableBinding} concrete method passing \( \text{varName} \) as the argument.
       ii. Assert: \( \text{status} \) is never an abrupt completion.
15. Let \( \text{lexDeclarations} \) be the \( \text{LexicalDeclarations} \) of \( \text{code} \).
16. For each element \( d \) in \( \text{lexDeclarations} \) do
    a. NOTE: A lexically declared name cannot be the same as a function declaration, formal parameter, or a var name. Lexically declared names are only instantiated here but not initialsed.
    b. For each element \( \text{dn} \) of the \( \text{BoundNames} \) of \( d \) do
       i. If \( \text{IsConstantDeclaration} \) of \( d \) is \text{true}, then
1. Call `env`'s `CreateImmutableBinding` concrete method passing `dn` as the argument.
   ii. Else
   1. Let `status` be the result of calling `env`'s `CreateMutableBinding` concrete method
      passing `dn` and `false` as the arguments.
   2. Assert: `status` is never an abrupt completion.
   c. If `d` is a `GeneratorDeclaration` production, then
      i. Append `d` to `functionsToInitialise`.
17. For each production `f` in `functionsToInitialise`, do
   a. Let `fn` be the sole element of the `BoundNames` of `f`.
   b. Let `fo` be the result of performing `InstantiateFunctionObject` for `f` with argument `env`.
   c. Let `status` be the result of calling `env`'s `SetMutableBinding` concrete method passing `fn`, `fo`, and `false` as the arguments.
   d. Assert: `status` is never an abrupt completion.
18. NOTE Function declaration are initialised prior to parameter initialisation so that default value expressions may reference them. "arguments" is not initialised until after parameter initialisation.
19. Let `ao` be the result of `InstantiateArgumentsObject` with argument `argumentsList`.
20. NOTE If `argumentsObjectNeeded` is `false` then the value of `ao` is not directly observable to ECMAScript code and need not actually exist. In that case, its use in the above steps is strictly as a device for specifying formal parameter initialisation semantics.
21. Let `formalStatus` be the result of performing `Binding Initialisation` for `formals` with `ao` and `undefined` as arguments.
22. ReturnIfAbrupt(`formalStatus`).
23. If `argumentsObjectNeeded` is `true`, then
   a. If `strict` is `true`, then
      i. Perform the abstract operation `CompleteStrictArgumentsObject` with argument `ao`.
   b. Else, if `func`, `formals`, and `env`.
      i. Perform the abstract operation `CompleteMappedArgumentsObject` with arguments `ao`, `func`, `formals`, and `env`.
   c. Call `env`'s `InitialiseBinding` concrete method passing "arguments" and `ao` as arguments.
24. Return `NormalCompletion`(`empty`).

9.2 Built-in Exotic Object Internal Methods and Data Fields

This specification defines several kinds of built-in exotic objects. These objects generally behave similar to ordinary objects except for a few specific situations. The following exotic objects use the ordinary object internal methods except where it is explicitly specified otherwise below:

9.2.1 Bound Function Exotic Objects

A bound function is an exotic object that wraps another function object. A bound function is callable (it has a `[[Call]]` internal method and may have a `[[Construct]]` internal method). Calling a bound function generally results in a call of its wrapped function.

Bound function objects do not have the internal data properties of ordinary function objects defined in Table 25. Instead they have the internal data properties defined in Table 26.

Table 26 -- Internal Data Properties of Exotic Bound Function Objects

<table>
<thead>
<tr>
<th>Internal Data Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[[BoundTargetFunction]]</code></td>
<td>Callable Object</td>
<td>The wrapped function object.</td>
</tr>
<tr>
<td><code>[[BoundThis]]</code></td>
<td>Any</td>
<td>The value that is always passed as the <code>this</code> value when calling the wrapped function.</td>
</tr>
<tr>
<td><code>[[BoundArguments]]</code></td>
<td>List of Any</td>
<td>A list of values that whose elements are used as the first arguments to any call to the wrapped function.</td>
</tr>
</tbody>
</table>

Unlike ordinary function objects, bound function objects do not use alternative definitions of the `[[Get]]` and `[[GetProperty]]` internal methods. Bound function objects provide all of the essential internal methods as specified in 9.1. However, they use the following definitions for the essential internal methods of function objects.
9.2.1.1 [[Call]]

When the [[Call]] internal method of an exotic bound function object, \( F \), which was created using the bind function is called with parameters \( \text{thisArgument} \) and \( \text{argumentsList} \), a List of ECMAScript language values, the following steps are taken:

1. Let \( \text{boundArgs} \) be the value of \( F \)'s [[BoundArguments]] internal data property.
2. Let \( \text{boundThis} \) be the value of \( F \)'s [[BoundThis]] internal data property.
3. Let \( \text{target} \) be the value of \( F \)'s [[BoundTargetFunction]] internal data property.
4. Let \( \text{args} \) be a new list containing the same values as the list \( \text{boundArgs} \) in the same order followed by the same values as the list \( \text{argumentsList} \) in the same order.
5. Return the result of calling the [[Call]] internal method of \( \text{target} \) providing \( \text{boundThis} \) as \( \text{thisArgument} \) and providing \( \text{args} \) as \( \text{argumentsList} \).

9.2.1.2 [[Construct]]

When the [[Construct]] internal method of an exotic bound function object, \( F \) that was created using the bind function is called with a list of arguments \( \text{ExtraArgs} \), the following steps are taken:

1. Let \( \text{target} \) be the value of \( F \)'s [[BoundTargetFunction]] internal data property.
2. Assert: \( \text{target} \) has a [[Construct]] internal method.
3. Let \( \text{boundArgs} \) be the value of \( F \)'s [[BoundArguments]] internal data property.
4. Let \( \text{args} \) be a new list containing the same values as the list \( \text{boundArgs} \) in the same order followed by the same values as the list \( \text{ExtraArgs} \) in the same order.
5. Return the result of calling the [[Construct]] internal method of \( \text{target} \) providing \( \text{args} \) as the arguments.

9.2.1.3 BoundFunctionCreate Abstract Operation

The abstract operation BoundFunctionCreate with arguments \( \text{targetFunction} \), \( \text{boundThis} \) and \( \text{boundArgs} \) is used to specify the creation of new Bound Function exotic objects. It performs the following steps:

1. Let \( \text{proto} \) be the intrinsic %FunctionPrototype%.
2. Let \( \text{obj} \) be a newly created ECMAScript object.
3. Set \( \text{obj} \)'s essential internal methods to the default ordinary object definitions specified in 9.1.
4. Set the [[Call]] internal method of \( \text{obj} \) as described in 9.2.1.1.
5. If \( \text{targetFunction} \) has a [[Construct]] internal method, then
   a. Set the [[Construct]] internal method of \( \text{obj} \) as described in 9.2.1.2.
6. Set the [[Prototype]] internal data property of \( \text{obj} \) to \( \text{proto} \).
7. Set the [[Extensible]] internal data property of \( \text{obj} \) to \( \text{true} \).
8. Set the [[BoundTargetFunction]] internal data property of \( \text{obj} \) to \( \text{targetFunction} \).
9. Set the [[BoundThis]] internal data property of \( \text{obj} \) to the value of \( \text{boundThis} \).
10. Set the [[BoundArguments]] internal data property of \( \text{obj} \) to \( \text{boundArgs} \).
11. Return \( \text{obj} \).

9.2.2 Array Exotic Objects

An Array object is an exotic object that gives special treatment to a certain class of property names. A property name \( P \) (in the form of a String value) is an array index if and only if \( \text{ToUint32}(\text{ToObject}(P)) \) is equal to \( P \) and \( \text{ToUint32}(P) \) is not equal to \( 2^{32} - 1 \). A property whose property name is an array index is also called an element. Every Array object has a \( \text{length} \) property whose value is always a nonnegative integer less than \( 2^{32} \). The value of the \( \text{length} \) property is numerically greater than the name of every property whose name is an array index; whenever a property of an Array object is created or changed, other properties are adjusted as necessary to maintain this invariant. Specifically, whenever a property is added whose name is an array index, the \( \text{length} \) property is changed, if necessary, to be one more than the numeric value of that array index; and whenever the \( \text{length} \) property is changed, every property whose name is an array index whose value is not smaller than the new length is automatically deleted. This constraint applies only to own properties of an Array object and is unaffected by \( \text{length} \) or array index properties that may be inherited from its prototypes.

Exotic Array objects have the same internal data properties as ordinary objects. They also have an [[ArrayInitialisationState]] internal data property.
Exotic Array objects always have a non-configurable property named "length".

Exotic Array objects provide an alternative definition for the [[DefineOwnProperty]] internal method. Except for that internal methods, exotic Array objects provide all of the other essential internal methods as specified in 9.1.

9.2.2.1 [[DefineOwnProperty]] ( P, Desc)

When the [[DefineOwnProperty]] internal method of an exotic Array object A is called with property key P, and Property Descriptor Desc the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. If P is "length", then
   a. Return the result of calling ArraySetLength with arguments A and Desc.
3. Else if P is an array index, then
   a. Let oldLenDesc be the result of calling the [[GetOwnProperty]] internal method of A passing "length" as the argument. The result will never be undefined or an accessor descriptor because Array objects are created with a length data property that cannot be deleted or reconfigured.
   b. Let oldLen be oldLenDesc.[[Value]].
   c. Let index be ToUint32(P).
   d. Assert: index will never be an abrupt completion.
   e. If index ≥ oldLen and oldLenDesc.[[Writable]] is false, then return false.
   f. Let succeeded be the result of calling OrdinaryDefineOwnProperty passing A, P, and Desc as arguments.
   g. ReturnIfAbrupt(succeeded).
   h. If succeeded is false, then return false.
   i. If index ≥ oldLen
      i. Set oldLenDesc.[[Value]] to index + 1.
      ii. Let succeeded be the result of calling OrdinaryDefineOwnProperty passing A, "length", and oldLenDesc as arguments.
      iii. ReturnIfAbrupt(succeeded).
   j. Return true.
4. Return the result of calling OrdinaryDefineOwnProperty passing A, P, and Desc as arguments.

9.2.2.2 ArrayCreate Abstract Operation

The abstract operation ArrayCreate with argument length (a positive integer or undefined) and optional argument proto is used to specify the creation of new exotic Array objects. It performs the following steps:

1. If the proto argument was not passed, then let proto be the intrinsic object %ArrayPrototype%.
2. Let A be a newly created Array exotic object.
3. Set A’s essential internal methods except for [[DefineOwnProperty]] to the default ordinary object definitions specified in 9.1.
4. Set the [[DefineOwnProperty]] internal method of A as specified in 9.2.2.1.
5. Set the [[Prototype]] internal data property of A to proto.
6. Set the [[Extensible]] internal data property of A to true.
7. If length is not undefined, then
   a. Set the [[ArrayInitialisationState]] internal data property of A to true.
8. Else
   a. Set the [[ArrayInitialisationState]] internal data property of A to false.
   b. Let length be 0.
9. Call OrdinaryDefineOwnProperty with arguments A, "length" and Property Descriptor {[[Value]]: length, [[Writable]]: true, [[Enumerable]]: false, [[Configurable]]: false}.
10. Return A.

9.2.2.3 ArraySetLength Abstract Operation

When the abstract operation ArraySetLength is called with an exotic Array object A, and Property Descriptor Desc the following steps are taken:
1. If the [[Value]] field of Desc is absent, then
   a. Return the result of calling OrdinaryDefineOwnProperty passing A, "length", and Desc as arguments.
2. Let newLenDesc be a copy of Desc.
3. Let newLen = ToUint32(Desc.[[Value]]).
4. If newLen is not equal to ToNumber(Desc.[[Value]]), throw a RangeError exception.
5. Set newLenDesc.[[Value]] to newLen.
6. Let oldLenDesc be the result of calling the [[GetOwnProperty]] internal method of A passing "length" as the argument. The result will never be undefined or an accessor descriptor because Array objects are created with a length data property that cannot be deleted or reconfigured.
7. Let oldLen = oldLenDesc.[[Value]].
8. If newLen ≥ oldLen, then
   a. Return the result of calling OrdinaryDefineOwnProperty passing A, "length", and newLenDesc as arguments.
9. If oldLenDesc.[[Writable]] is false, then return false.
10. If newLenDesc.[[Writable]] is absent or has the value true, let newWritable be true.
11. Else,
   a. Need to defer setting the [[Writable]] attribute to false in case any elements cannot be deleted.
   b. Let newWritable be false.
   c. Set newLenDesc.[[Writable]] to true.
12. Let succeeded be the result of calling OrdinaryDefineOwnProperty passing A, "length", and newLenDesc as arguments.
13. ReturnIfAbrupt(succeeded).
14. If succeeded is false, return false.
15. While newLen < oldLen repeat,
   a. Set oldLen to oldLen – 1.
   b. Let deleteSucceeded be the result of calling the [[Delete]] internal method of A passing ToString(oldLen).
   c. ReturnIfAbrupt(deleteSucceeded).
   d. If deleteSucceeded is false, then
      i. Set newLenDesc.[[Value]] to oldLen+1.
      ii. If newWritable is false, set newLenDesc.[[Writable]] to false.
      iii. Let succeeded be the result of calling OrdinaryDefineOwnProperty passing A, "length", and newLenDesc as arguments.
      iv. ReturnIfAbrupt(succeeded).
      v. Return false.
16. If newWritable is false, then
   a. Call OrdinaryDefineOwnProperty passing A, "length", and Property Descriptor([[Writable]]: false) as arguments. This call will always return true.
17. Return true.

9.2.3 String Exotic Objects

A String object is an exotic object that encapsulates a String value and exposes virtual integer indexed data properties corresponding to the individual code unit elements of the string value. Exotic String objects always have a data property named "length" whose value is the number of code unit elements in the encapsulated String value. Both the code unit data properties and the "length" property are non-writable and non-configurable.

Exotic String objects have the same internal data properties as ordinary objects. They also have a [[StringLength]] internal data property.

Exotic String objects provide alternative definitions for the following internal methods. All of the other exotic String object essential internal methods that are not defined below are as specified in 9.1.

9.2.3.1 [[HasOwnProperty]] (P)
When the [[HasOwnProperty]] internal method of exotic String object O is called with property key P, the following steps are taken:
1. Assert: IsPropertyKey(P) is true.
2. Let has be the result of calling the ordinary object [[HasOwnProperty]] internal method (9.1.5) on O with argument P.
3. ReturnIfAbrupt(has).
4. If has is true, then return true.
5. If Type(P) is not String, then return false.
6. Let index be ToInteger(P).
7. Assert: index is not an abrupt completion.
8. Let absIntIndex be ToString(abs(index)).
9. If SameValue(absIntIndex, P) is false return false.
10. Let str be the String value of the `[[StringData]]` internal property of O, if the value of `[[StringData]]` is undefined the empty string is used as its value.
11. Let len be the number of elements in str.
12. If len ≤ index, return false.
13. Return true.

9.2.3.2 `[[GetOwnProperty]] ( P )`

When the `[[GetOwnProperty]]` internal method of an exotic String object S is called with property key P the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Let desc be the result of OrdinaryGetOwnProperty(S, P).
3. ReturnIfAbrupt(desc).
4. If desc is not undefined return desc.
5. If Type(P) is not String, then return undefined.
6. Let index be ToInteger(P).
7. Assert: index is not an abrupt completion.
8. Let absIntIndex be ToString(abs(index)).
9. If SameValue(absIntIndex, P) is false return undefined.
10. Let str be the String value of the `[[StringData]]` internal data property of S, if the value of `[[StringData]]` is undefined the empty string is used as its value.
11. Let len be the number of elements in str.
12. If len ≤ index, return undefined.
13. Let resultStr be a String value of length 1, containing one code unit from str, specifically the code unit at position index, where the first (leftmost) element in str is considered to be at position 0, the next one at position 1, and so on.
14. Return a Property Descriptor `{ [[Value]]: resultStr, [[Enumerable]]: true, [[Writable]]: false, [[Configurable]]: false }`.

9.2.3.3 `[[DefineOwnProperty]] ( P, Desc )`

When the `[[DefineOwnProperty]]` internal method of an exotic String object O is called with property key P, and Property Descriptor Desc the following steps are taken:

1. Let current be the result of calling the `[[GetOwnProperty]]` internal method of O with argument P.
2. Let extensible be the value of the `[[Extensible]]` internal data property of O.
3. Return the result of ValidateAndApplyPropertyDescriptor with arguments O, P, extensible, Desc, and current.

NOTE This algorithm differs from the ordinary object OrdinaryDefineOwnProperty abstract operation algorithm only in invocation of `[[GetOwnProperty]]` in step 1.

9.2.3.4 `[[Enumerate]] ()`

When the `[[Enumerate]]` internal method of an exotic String object O is called the following steps are taken:

1. Let current be the result of calling the `[[Enumerate]]` internal method of O with argument P.
2. Let extensible be the value of the `[[Extensible]]` internal data property of O.
3. Return the result of ValidateAndApplyPropertyDescriptor with arguments O, P, extensible, Desc, and current.

NOTE This algorithm differs from the ordinary object OrdinaryDefineOwnProperty abstract operation algorithm only in invocation of `[[GetOwnProperty]]` in step 1.
9.2.3.5 [[OwnPropertyKeys]] ()

When the [[OwnPropertyKeys]] internal method of an exotic String object $O$ is called, the following steps are taken:

9.2.3.6 StringCreate Abstract Operation

The abstract operation StringCreate with argument $prototype$ is used to specify the creation of new exotic String objects. It performs the following steps:

1. Let $A$ be a newly created String exotic object.
2. Set $A$’s essential internal methods to the default ordinary object definitions specified in 9.1.
3. Set the [[HasOwnProperty]] internal method of $A$ as specified in 9.2.3.1.
4. Set the [[GetOwnProperty]] internal method of $A$ as specified in 9.2.3.2.
5. Set the [[DefineOwnProperty]] internal method of $A$ as specified in 9.2.3.3.
6. Set the [[Enumerate]] internal method of $A$ as specified in 9.2.3.4.
7. Set the [[OwnPropertyKeys]] internal method of $A$ as specified in 9.2.3.5.
8. Set the [[Enumerate]] internal method of $A$ to $prototype$.
9. Set the [[Extensible]] internal data property of $A$ to true.
10. Return $A$.

9.2.4 Symbol Exotic Objects

A Symbol object is an exotic object that may be used as a property key. Symbol exotic objects are always immutable and never observably reference any other object.

Exotic Symbol objects provide alternative definitions for all of the essential internal methods.

9.2.4.1 [[GetInheritance]] ()

When the [[GetInheritance]] internal method of an exotic Symbol object $O$ is called, the following steps are taken:

1. Return null.

9.2.4.2 [[SetInheritance]] (V)

When the [[SetInheritance]] internal method of an exotic Symbol object $O$ is called with argument $V$, the following steps are taken:

1. Assert: Either Type($V$) is Object or Type($V$) is Null.
2. Return false.

9.2.4.3 [[IsExtensible]] ()

When the [[IsExtensible]] internal method of an exotic Symbol object $O$ is called, the following steps are taken:

1. Return false.

9.2.4.4 [[PreventExtensions]] ()

When the [[PreventExtensions]] internal method of an exotic Symbol object $O$ is called, the following steps are taken:

1. Return true.
9.2.4.5  \[[\text{HasOwnProperty}]\] (P)
When the \[[\text{HasOwnProperty}]\] internal method of an exotic Symbol object \(O\) is called with property key \(P\), the following steps are taken:

1. Return false.

9.2.4.6  \[[\text{GetOwnProperty}]\] (P)
When the \[[\text{GetOwnProperty}]\] internal method of an exotic Symbol object \(O\) is called with property key \(P\), the following steps are taken:

1. Return undefined.

9.2.4.7  \[[\text{DefineOwnProperty}]\] (P, Desc)
When the \[[\text{DefineOwnProperty}]\] internal method of an exotic Symbol object \(O\) is called with property key \(P\) and property descriptor \(\text{Desc}\), the following steps are taken:

1. Return false.

9.2.4.8  \[[\text{HasProperty}]\] (P)
When the \[[\text{HasProperty}]\] internal method of an exotic Symbol object \(O\) is called with property key \(P\), the following steps are taken:

1. Return false.

9.2.4.9  \[[\text{Get}]\] (P, Receiver)
When the \[[\text{Get}]\] internal method of an exotic Symbol object \(O\) is called with property key \(P\) and ECMAScript language value \(\text{Receiver}\) the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Return undefined.

9.2.4.10  \[[\text{Set}]\] (P, V, Receiver)
When the \[[\text{Set}]\] internal method of an exotic Symbol object \(O\) is called with property key \(P\), value \(V\), and ECMAScript language value \(\text{Receiver}\), the following steps are taken:

1. Return false.

9.2.4.11  \[[\text{Invoke}]\] (P, ArgumentsList, Receiver)
When the \[[\text{Invoke}]\] internal method of an exotic Symbol object \(O\) is called with property key \(P\), List \(\text{ArgumentsList}\), and ECMAScript language value \(\text{Receiver}\) the following steps are taken:

1. Throw a TypeError exception.

9.2.4.12  \[[\text{Delete}]\] (P)
When the \[[\text{Delete}]\] internal method of an exotic Symbol object \(O\) is called with property key \(P\) the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Return true.

9.2.4.13  \[[\text{Enumerate}]\] ()
When the \[[\text{Enumerate}]\] internal method of an exotic Symbol object \(O\) is called the following steps are taken:
1. Return the result of CreateEmptyIterator().

9.2.4.14  [[OwnPropertyKeys]] ()

When the [[OwnPropertyKeys]] internal method of an exotic Symbol object O is called the following steps are taken:

1. Return the result of CreateEmptyIterator().

9.2.5  Exotic Arguments Objects

An arguments object is an exotic object whose array index properties map to the formal parameters bindings of an invocation of a non-strict function.

Exotic arguments objects have the same internal data properties as ordinary objects. They also have a [[ParameterMap]] internal data.

Exotic arguments objects provide alternative definitions for the following internal methods. All of the other exotic arguments object essential internal methods that are not defined below are as specified in 9.1.

9.2.5.1  Arguments Object

When function code is evaluated, an arguments object is created unless (as specified in 9.1.16.11) the identifier arguments occurs as an Identifier in the function’s FormalParameters or occurs as the BindingIdentifier of a FunctionDeclaration contained in the outermost StatementList of the function code.

The abstract operation InstantiateArgumentsObject called with an argument args performs the following steps:

1. Let len be the number of elements in args.
2. Let obj be the result of the abstract operation ObjectCreate with the intrinsic object %ObjectPrototype% as its argument.
3. Call the [[DefineOwnProperty]] internal method on obj passing “length” and the Property Descriptor {[[Value]]: len, [[Writable]]: true, [[Enumerable]]: false, [[Configurable]]: true} as arguments.
4. Let indx = len - 1.
5. Repeat while indx ≥ 0,
   a. Let val be the element of args at 0-originated list position indx.
   b. Call the [[DefineOwnProperty]] internal method on obj passing ToString(indx) and the Property Descriptor {[[Value]]: val, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true} as arguments.
   c. Let indx = indx - 1.
6. Return obj.

The abstract operation CompleteStrictArgumentsObject is called with argument obj which must have been previously created by the abstract operation InstantiateArgumentsObject. The following steps are performed:

1. Perform the AddRestrictedFunctionProperties abstract operation with argument obj.
2. Return.

The abstract operation CompleteMappedArgumentsObject is called with argument obj, object func, grammar production formats, and environment record env. obj must have been previously created by the abstract operation InstantiateArgumentsObject. The following steps are performed:

1. Let len be the result of Get(obj, "length").
2. Let mappedNames be an empty List.
3. Let numberOfNonRestFormals be NumberOfParameters of formats.
4. Let map be the result of the abstract operation ObjectCreate with the intrinsic object %ObjectPrototype% as its argument.
5. Let indx = len - 1.

Commented [AWB 223]: Additional modification to this text will probably be need to account for the new declaration statements.
6. Repeat while \( \text{indx} \geq 0 \),
   a. If \( \text{indx} \) is less than the number of non-rest formals, then
      i. Let \( \text{param} \) be getParameter of \( \text{formals} \) with argument \( \text{indx} \).
      ii. If \( \text{param} \) is a BindingIdentifier, then
          1. Let \( \text{name} \) be the sole element of BoundNames of \( \text{param} \).
          2. If \( \text{name} \) is not an element of \( \text{mappedNames} \), then
              a. Add \( \text{name} \) as an element of the list \( \text{mappedNames} \).
              b. Let \( g \) be the result of calling the MakeArgGetter abstract operation with arguments \( \text{name} \) and \( \text{env} \).
              c. Let \( p \) be the result of calling the MakeArgSetter abstract operation with arguments \( \text{name} \) and \( \text{env} \).
              d. Call the [[DefineOwnProperty]] internal method of \( \text{map} \) passing arguments \( \text{name} \) and \( \text{env} \).
              e. If \( \text{_indx} \) is not an element of \( \text{mappedNames} \), then
                  a. Add \( \text{_indx} \) as an element of the list \( \text{mappedNames} \).
                  b. Let \( \text{indx} = \text{indx} - 1 \).
      b. Else if \( \text{ indx } \) contains a formal parameter mapping for \( \text{param} \), then
          1. Let \( \text{indx} \) be the sole element of BoundNames of \( \text{param} \).
          2. Set the [[GetOwnProperty]] internal method of \( \text{map} \) to the definitions provided below.
     8. Call the [[DefineOwnProperty]] internal method on \( \text{obj} \) passing "callee" and the Property Descriptor
        \( [[Value]]: \text{func}, [[Writable]]: \text{true}, [[Enumerable]]: \text{false}, [[Configurable]]: \text{true} \) as arguments.
   9. Return \( \text{obj} \)

The abstract operation MakeArgGetter called with String \( \text{name} \) and environment record \( \text{env} \) creates a function object that when executed returns the value bound for \( \text{name} \) in \( \text{env} \). It performs the following steps:

1. Let \( \text{bodyText} \) be the result of concatenating the Strings "return \( \text{name} \), and ; \".
2. Let \( \text{body} \) be the result of parsing \( \text{bodyText} \) using FunctionBody as the goal symbol.
3. Let \( \text{parameters} \) be a FormalParameters : (empty) production.
4. Return the result of calling the abstract operation FunctionCreate using Normal as the \( \text{kind} \), \( \text{parameters} \) as \( \text{FormalParameterList} \), \( \text{body} \) as \( \text{FunctionBody} \), env as Scope, and \text{true} for Strict.

The abstract operation MakeArgSetter called with String \( \text{name} \) and environment record \( \text{env} \) creates a function object that when executed sets the value bound for \( \text{name} \) in \( \text{env} \). It performs the following steps:

1. Let \( \text{paramText} \) be the String \( \text{name} \) concatenated with the String " \( \text{name} \), and ; \".
2. Let \( \text{parameters} \) be the result of parsing \( \text{paramText} \) using FormalParameters as the goal symbol.
3. Let \( \text{bodyText} \) be the String " \( \text{name} \) \( \text{param} \) \" with \( \text{name} \) replaced by the value of \( \text{name} \) and \( \text{param} \) replaced by the value of \( \text{paramText} \).
4. Let \( \text{body} \) be the result of parsing \( \text{bodyText} \) using FunctionBody as the goal symbol.
5. Return the result of calling the abstract operation FunctionCreate using Normal as the \( \text{kind} \), \( \text{parameters} \) as \( \text{FormalParameterList} \), \( \text{body} \) as \( \text{FunctionBody} \), env as Scope, and \text{true} for Strict.

The [[Get]] internal method of an arguments object for a non-strict mode function with formal parameters when called with a property name \( \text{P} \) performs the following steps:

1. Let \( \text{args} \) be the arguments object.
2. Let \( \text{map} \) be the value of the [[ParameterMap]] internal data property of the arguments object.
3. Let \( \text{isMapped} \) be the result of calling the [[GetOwnProperty]] internal method of \( \text{map} \) passing \( \text{P} \) as the argument.
4. If the value of \( \text{isMapped} \) is undefined, then
   a. Let \( v \) be the result of calling the default ordinary object [[Get]] internal method (9.1.9) on \( \text{args} \) passing \( \text{P} \) and \( \text{args} \) as the arguments.
   b. If \( \text{P} \) is "callee" and \( v \) is a strict mode Function object, throw a TypeError exception.
   c. Return \( v \).
5. Else \( \text{map} \) contains a formal parameter mapping for \( \text{P} \).
   a. Return the result of calling Get(map, \( \text{P} \)).

The [[DefineOwnProperty]] internal method of an arguments object for a non-strict mode function with formal parameters when called with a property name \( \text{P} \) performs the following steps:
The [[DefineOwnProperty]] internal method of an arguments object for a non-strict mode function with formal parameters when called with a property name P and Property Descriptor Desc performs the following steps:

1. Let map be the value of the [[ParameterMap]] internal data property of the arguments object.
2. Let isMapped be the result of calling the [[GetOwnProperty]] internal method of map passing P as the argument.
3. Let result be the result of calling the default [[DefineOwnProperty]] internal method of object passing P and Desc as the arguments.
4. ReturnIfAbrupt(result).
5. If the value of isMapped is not undefined, then
   a. Set desc.[[Value]] to the result of calling Get(map, P).
6. Return desc.

The [[DefineOwnProperty]] internal method of an arguments object for a non-strict mode function with formal parameters when called with a property name P and Property Descriptor Desc performs the following steps:

1. Let map be the value of the [[ParameterMap]] internal data property of the arguments object.
2. Let isMapped be the result of calling the [[GetOwnProperty]] internal method of map passing P as the argument.
3. Let allowed be the result of calling the default [[DefineOwnProperty]] internal method for ordinary objects (9.1.7) on the arguments object passing P and Desc as the arguments.
4. ReturnIfAbrupt(allowed).
5. If allowed is false, then return false.
6. If the value of isMapped is not undefined, then
   a. If IsAccessorDescriptor(desc) is true, then
      i. Call the [[Delete]] internal method of map passing P as the argument.
   b. Else
      i. If Desc.[[Value]] is present, then
         1. Let putStatus be the result of Put(map, P, Desc.[[Value]], false).
         2. Assert: putStatus is true because formal parameters mapped by argument objects are always writable.
      ii. If Desc.[[Writable]] is present and its value is false, then
         1. Call the [[Delete]] internal method of map passing P as the argument.
7. Return true.

The [[Delete]] internal method of an arguments object for a non-strict mode function with formal parameters when called with a property key P performs the following steps:

1. Let map be the value of the [[ParameterMap]] internal data property of the arguments object.
2. Let isMapped be the result of calling the [[GetOwnProperty]] internal method of map passing P as the argument.
3. Let result be the result of calling the default [[Delete]] internal method for ordinary objects (9.1.12) on the arguments object passing P as the argument.
4. If result is true and the value of isMapped is not undefined, then
   a. Call the [[Delete]] internal method of map passing P as the argument.
5. Return result.

NOTE 1 For non-strict mode functions the integer indexed data properties of an arguments object whose numeric name values are less than the number of formal parameters of the corresponding function object initially share their values with the corresponding argument bindings in the function's execution context. This means that changing the property changes the corresponding value of the argument binding and vice-versa. This correspondence is broken if such a property is deleted and then redefined or if the property is changed into an accessor property. For strict mode functions, the values of the arguments object's properties are simply a copy of the arguments passed to the function and there is no dynamic linkage between the property values and the formal parameter values.

NOTE 2 The ParameterMap object and its property values are used as a device for specifying the arguments object correspondence to argument bindings. The ParameterMap object and the objects that are the values of its properties are not directly accessible from ECMAScript code. An ECMAScript implementation does not need to actually create or use such objects to implement the specified semantics.

NOTE 3 Arguments objects for strict mode functions define non-configurable accessor properties named 'callee' and 'call' which throw a TypeError exception on access. The 'callee' property has a more specific meaning for non-strict mode functions and a 'call' property has historically been provided as an implementation-defined extension by some ECMAScript implementations. The strict mode definition of these properties exists to ensure that neither of them is defined in any other manner by conforming ECMAScript implementations.

© Ecma International 2013
9.2.6 Integer Indexed Exotic Objects

An Integer Indexed object is an exotic object that performs special handling of integer property keys.

Integer Indexed exotic objects have the same internal data properties as ordinary objects additionally [[ViewedArrayBuffer]], [[ArrayLength]], [[ByteOffset]], and [[TypedArrayName]] internal data properties.

Integer Indexed Exotic objects provide alternative definitions for the following internal methods. All of the other Integer Indexed exotic object essential internal methods that are not defined below are as specified in 9.1.

9.2.6.1 [[HasOwnProperty]] (P)

When the [[HasOwnProperty]] internal method of an Integer Indexed exotic object O is called with property key P, the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Assert: O is an Object that has a [[ViewedArrayBuffer]] internal data.
3. If Type(P) is String, then
   a. Let intIndex be ToInteger(P).
   b. Assert: intIndex is not an abrupt completion.
   c. If SameValue(ToString(intIndex), P) is true, then
      i. If intIndex < 0, then return false.
      ii. Let length be the value of O’s [[ArrayLength]] internal data property.
      iii. If length is undefined, then throw a TypeError exception.
      iv. If intIndex ≥ length, then return false.
   v. Return true.
4. Return the result of calling the ordinary object [[HasOwnProperty]] internal method (9.1.5) on O with argument P.

9.2.6.2 [[GetOwnProperty]] (P)

When the [[GetOwnProperty]] internal method of an Integer Indexed exotic object O is called with property key P the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Assert: O is an Object that has a [[ViewedArrayBuffer]] internal data.
3. If Type(P) is String, then
   a. Let intIndex be ToInteger(P).
   b. Assert: intIndex is not an abrupt completion.
   c. If SameValue(ToString(intIndex), P) is true, then
      i. Let value be the result of IntegerIndexedElementGet(O, intIndex).
      ii. ReturnIfAbrupt(value).
      iii. If value is undefined, then return undefined.
      iv. Let writable be true if the integer indexed properties of O are writable and false if they are not.
   v. Return a Property Descriptor { [[Value]]: value, [[Enumerable]]: true, [[Writable]]: writable, [[Configurable]]: false }.
4. Return the result of OrdinaryGetOwnProperty(O, P).

9.2.6.3 [[DefineOwnProperty]] (P, Desc)

When the [[DefineOwnProperty]] internal method of an Integer Indexed exotic object O is called with property key P, and Property Descriptor Desc the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Assert: O is an Object that has a [[ViewedArrayBuffer]] internal data.
3. If Type(P) is String, then
   a. Let intIndex be ToInteger(P).
   b. Assert: intIndex is not an abrupt completion.
c. If SameValue(ToString(intIndex), P) is true, then
   i. If intIndex < 0, then return false.
   ii. Let length be the value of O’s [[ArrayLength]] internal data property.
   iii. If length is undefined, then throw a TypeError exception.
   iv. If intIndex ≥ length, then return false.
   v. If IsAccessorDescriptor(Desc) is true, then return false.
   vi. If Descs a [[Configurable]] field and if Desc.$isConfigurable is true, then return false.
   vii. If Descs an [[Enumerable]] field and if Desc.$isEnumerable is false, then return false.
   viii. Let writable be true if the integer indexed properties of O are writable and false if they are not.
   ix. Let makeReadOnly be false.
   x. If Descs a [[Writable]] field, then
      1. If Desc.$isWritable is true and writable is false, then return false.
      2. If Desc.$isWritable is false and writable is true, then let makeReadOnly be true.
   xi. If Descs an [[Value]] field, then
      1. Let value be Desc.$isValue.
      2. If writable is false, then
         a. Let oldValue be the result of IntegerIndexedElementGet (O, intIndex).
         b. ReturnIfAbrupt(oldValue).
         c. If oldValue is undefined, then return false.
         d. If SameValue(value, oldValue) is false, then return false.
      3. Else
         a. Let status be the result of IntegerIndexedElementSet (O, intIndex, value).
         b. ReturnIfAbrupt(status).
   xii. If makeReadOnly is true, then mark the integer indexed properties of O as non-writable.
   xiii. Return true.

4. Return the result of OrdinaryGetOwnProperty(O, P).

9.2.6.4 [[Get]] (P, Receiver)

When the [[Get]] internal method of an Integer Indexed exotic object O is called with property key P and ECMAScript language value Receiver the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. If Type(P) is String and if SameValue(O, Receiver) is true, then
   a. Let intIndex be ToInteger(P).
   b. Assert: intIndex is not an abrupt completion.
   c. If SameValue(ToString(intIndex), P) is true, then
      i. Return the result of ToBoolean(IntegerIndexedElementGet (O, intIndex)).
3. Return the result of calling the default ordinary object [[Get]] internal method (9.1.9) on O passing P and Receiver as arguments.

9.2.6.5 [[Set]] (P, V, Receiver)

When the [[Set]] internal method of an Integer Indexed exotic object O is called with property key P, value V, and ECMAScript language value Receiver, the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. If Type(P) is String and if SameValue(O, Receiver) is true, then
   a. Let intIndex be ToInteger(P).
   b. Assert: intIndex is not an abrupt completion.
   c. If SameValue(ToString(intIndex), P) is true, then
      i. Return the result of ToBoolean(IntegerIndexedElementSet (O, intIndex, V)).
3. Return the result of calling the default ordinary object [[Set]] internal method (9.1.9) on O passing P, V, and Receiver as arguments.
9.2.6 Abstract Operation

Create Abstract Operation.

9.2.7 [OwnProperty] ()

9.2.8 IntegerIndexedObjectCreate Abstract Operation

The abstract operation IntegerIndexedObjectCreate with argument `prototype` is used to specify the creation of new Integer Indexed exotic objects. It performs the following steps:

1. Let `A` be a newly created ECMAScript object.
2. Set `A`’s essential internal methods to the default ordinary object definitions specified in 9.1.
3. Set the `[[HasOwnProperty]]` internal method of `A` as specified in 9.2.6.1.
4. Set the `[[GetOwnProperty]]` internal method of `A` as specified in 9.2.6.2.
5. Set the `[[DefineOwnProperty]]` internal method of `A` as specified in 9.2.6.3.
6. Set the `[[Get]]` internal method of `A` as specified in 9.2.6.4.
7. Set the `[[Set]]` internal method of `A` as specified in 9.2.6.5.
8. Set the `[[Enumerate]]` internal method of `A` as specified in 9.2.6.6.
9. Set the `[[OwnPropertyKeys]]` internal method of `A` as specified in 9.2.6.7.
10. Set the `[[Prototype]]` internal data property of `A` to `prototype`.
11. Set the `[[Extensible]]` internal data property of `A` to `true`.
12. Return `A`.

9.2.9 IntegerIndexedElementGet ( O, index ) Abstract Operation

1. Assert: `Type(index)` is `Number` and `index` is an integer.
2. Assert: `O` is an Object that has `[[ViewedArrayBuffer]]`, `[[ArrayLength]]`, `[[ByteOffset]]`, and `[[TypedArrayName]]` internal data properties.
3. Let `buffer` be the value of `O`’s `[[ViewedArrayBuffer]]` internal data property.
4. If `buffer` is `undefined`, then throw a `TypeError` exception.
5. Let `length` be the value of `O`’s `[[ArrayLength]]` internal data property.
6. If `index < 0` or `index ≥ length`, then return `undefined`.
7. Let `offset` be the value of `O`’s `[[ByteOffset]]` internal data property.
8. Let `arrayTypeName` be the string value of `O`’s `[[TypedArrayName]]` internal data property.
9. Let `elementType` be the `Number` value of the `Element Size` value specified in Table 36 for `arrayTypeName`.
10. Let `indexedPosition` = `(index × elementType) + offset`.
11. Let `elementType` be the string value of the `Element Type` value in `arrayTypeName`.
12. Return the result of `GetValueFromBuffer(buffer, indexedPosition, elementType)`.

9.2.10 IntegerIndexedElementSet ( O, index, value ) Abstract Operation

1. Assert: `Type(index)` is `Number` and `index` is an integer.
2. Assert: `O` is an Object that has `[[ViewedArrayBuffer]]`, `[[ArrayLength]]`, `[[ByteOffset]]`, and `[[TypedArrayName]]` internal data properties.
3. Let `buffer` be the value of `O`’s `[[ViewedArrayBuffer]]` internal data property.
4. If `buffer` is `undefined`, then throw a `TypeError` exception.
5. Let `length` be the value of `O`’s `[[ArrayLength]]` internal data property.
6. Let `numValue` be `ToNumber(value)`.
7. ReturnIfAbrupt(`numValue`).
8. If `index < 0` or `index ≥ length`, then return `false`.
9. Let `offset` be the value of `O`’s `[[ByteOffset]]` internal data property.
10. Let `arrayTypeName` be the string value of `O`’s `[[TypedArrayName]]` internal data property.
11. Let `elementType` be the `Number` value of the `Element Size` value specified in Table 36 for `arrayTypeName`.
12. Let `indexedPosition` = `(index × elementType) + offset`.
13. Let `elementType` be the string value of the `Element Type` value in `arrayTypeName`.
14. Let `status` be the result of `SetValueInBuffer(buffer, indexedPosition, elementType, numValue)`.
15. ReturnIfAbrupt(`status`).
16. Return `true`.
9.2.7 Built-in Function Objects

The built-in function objects defined in this specification may be implemented as either ordinary function objects whose behaviour is provided using ECMAScript code or as implementation provided exotic function objects whose behaviour is provided in some other manner. In either case, the effect of calling such functions must conform to their specifications.

If an implementation provided exotic object is used, the object must have the ordinary object behaviour specified in 9.1 except for [[Get]] and [[GetOwnProperty]] which must be as specified in 9.1.16. All such exotic function objects also have [[Prototype]] and [[Extensible]] internal data.

[[Call]] and [[Construct]]

9.2.7.1 CreateBuiltinFunction Abstract Operation

The abstract operation CreateBuiltinFunction takes a single argument, steps, that is a list of algorithm steps. It returns a built-in function object created by following steps:

1. Let func be a new built-in function object, in the current Realm, that when called performs the action described by steps.
2. Return func.

9.3 Proxy Object Internal Methods and Internal Data Properties

A proxy object is an exotic object whose essential internal methods are partially implemented using ECMAScript code. Every proxy objects has an internal data property called [[ProxyHandler]]. The value of [[ProxyHandler]] is always an object, called the proxy’s handler object. Methods of a handler object may be used to augment the implementation for one or more of the proxy objects internal methods. Every proxy object also has an internal data property called [[ProxyTarget]] whose value is either an object or the null value. This object is called the proxy’s target object.

When a handler method is called to provide the implementation of a proxy object internal method, the handler method is passed the proxy’s target object as a parameter. A proxy’s handler object does not necessarily have a method corresponding to every essential internal method. Invoking an internal method on the proxy results in the invocation of the corresponding internal method on the proxy’s target object if the handler object does not have a method corresponding to the internal trap.

The [[ProxyHandler]] and [[ProxyTarget]] internal data properties of a proxy object are always initialised when the object is created and typically may not be modified. Some proxy objects are created in a manner that permits them to be subsequently revoked. When a proxy is revoked, its [[ProxyHandler]] internal data property is set to a special revoked proxy handler object and its [[ProxyTarget]] internal data property is set to null.

Because proxy permit arbitrary ECMAScript code to be used to in the implementation of internal methods, it is possible to define a proxy object whose handler methods violates the invariants defined in 6.1.6.3. Some of the internal method invariants defined in 6.1.6.3 are essential integrity invariants. These invariants are explicitly enforced by the proxy internal methods specified in this section. An ECMAScript implementation must be robust in the presence of all possible invariant violations.

In the following algorithm descriptions, assume O is an ECMAScript proxy object, P is a property key value, V is any ECMAScript language value, Desc is a Property Description record, and B is a Boolean flag.

9.3.1 [[GetInheritance]] ()

When the [[GetInheritance]] internal method of an exotic Proxy object O is called the following steps are taken:

1. Let handler be the value of the [[ProxyHandler]] internal data property of O.
2. Let target be the value of the [[ProxyTarget]] internal data property of O.
3. Let trap be the result of GetMethod(handler, "getPrototypeOf").
4. ReturnIfAbrupt(trap).
5. If trap is undefined, then
   a. Return the result of calling the [[GetInheritance]] internal method of target.
6. Let handlerProto be the result of calling the [[Call]] internal method of trap with handler as the this value and a new List containing target.
7. ReturnIfAbrupt(handlerProto).
8. Let targetProto be the result of calling the [[GetInheritance]] internal method of target.
9. ReturnIfAbrupt(targetProto).
10. If SameValue(handlerProto, targetProto) is false, then throw a TypeError exception.

NOTE
[[GetInheritance]] for proxy objects enforces the following invariant:

• [[GetInheritance]] applied to the proxy object must return the same value as [[GetInheritance]] applied to the proxy object’s target object.

9.3.2 [[SetInheritance]] (V)

When the [[SetInheritance]] internal method of an exotic Proxy object O is called with argument V the following steps are taken:

1. Assert: Either Type(V) is Object or Type(V) is Null.
2. Let handler be the value of the [[ProxyHandler]] internal data property of O.
3. Let target be the value of the [[ProxyTarget]] internal data property of O.
4. Let trap be the result of GetMethod(handler, "setPrototypeOf").
5. ReturnIfAbrupt(trap).
6. If trap is undefined, then
   a. Return the result of calling the [[SetInheritance]] internal method of target with argument V.
7. Let trapResult be the result of calling the [[Call]] internal method of trap with handler as the this value and a new List containing target and V.
8. ReturnIfAbrupt(trapResult).
9. Let trapResult be ToBoolean(trapResult).
10. Let extensibleTarget be the result of IsExtensible(target).
11. ReturnIfAbrupt(extensibleTarget).
12. If extensibleTarget is true, then return trapResult.
13. Let targetProto be the result of calling the [[GetInheritance]] internal method of target.
14. ReturnIfAbrupt(targetProto).
15. If trapResult is true and SameValue(V, targetProto) is false, then throw a TypeError exception.
16. Return trapResult.

NOTE
[[SetInheritance]] for proxy objects enforces the following invariant:

• If the target object is not extensible, the argument value must be the same as the result of [[GetInheritance]] applied to target object.

9.3.3 [[IsExtensible]] ()

When the [[IsExtensible]] internal method of an exotic Proxy object O is called the following steps are taken:

1. Let handler be the value of the [[ProxyHandler]] internal data property of O.
2. Let target be the value of the [[ProxyTarget]] internal data property of O.
3. Let trap be the result of GetMethod(handler, "isExtensible").
4. ReturnIfAbrupt(trap).
5. If trap is undefined, then
   a. Return the result of calling the [[IsExtensible]] internal method of target.
6. Let trapResult be the result of calling the [[Call]] internal method of trap with handler as the this value and a new List containing target.
7. ReturnIfAbrupt(trapResult).
8. Let booleanTrapResult be ToBoolean(trapResult).
9. Let targetResult be the result of calling the [[IsExtensible]] internal method of target.
10. ReturnIfAbrupt(targetResult).
11. If SameValue(booleanTrapResult, targetResult) is false, then throw a TypeError exception.
12. Return booleanTrapResult.
NOTE  [[IsExtensible]] for proxy objects enforces the following invariant:
- [[IsExtensible]] applied to the proxy object must return the same value as [[IsExtensible]] applied to the proxy object’s target object with the same argument.

9.3.4  [[PreventExtensions]] ( )

When the [[PreventExtensions]] internal method of an exotic Proxy object O is called the following steps are taken:

1. Let handler be the value of the [[ProxyHandler]] internal data property of O.
2. Let target be the value of the [[ProxyTarget]] internal data property of O.
3. Let trap be the result of GetMethod(handler, "preventExtensions").
4. ReturnIfAbrupt(trap).
5. If trap is undefined, then
   a. Return the result of calling the [[PreventExtensions]] internal method of target.
6. Let trapResult be the result of calling the [[Call]] internal method of trap with handler as the this value and a new List containing target. Let booleanTrapResult be ToBoolean(trapResult).
7. ReturnIfAbrupt(booleanTrapResult).
8. Let targetIsExtensible be the result of calling the [[IsExtensible]] internal method of target.
9. ReturnIfAbrupt(targetIsExtensible).
10. If booleanTrapResult is true and targetIsExtensible is true, then throw a TypeError exception.

NOTE  [[PreventExtensions]] for proxy objects enforces the following invariant:
- [[PreventExtensions]] applied to the proxy object only returns true if [[IsExtensible]] applied to the proxy object’s target object is false.

9.3.5  [[HasOwnProperty]] (P)

When the [[HasOwnProperty]] internal method of an exotic Proxy object O is called with property key P, the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Let handler be the value of the [[ProxyHandler]] internal data property of O.
3. Let target be the value of the [[ProxyTarget]] internal data property of O.
4. Let trap be the result of GetMethod(handler, "hasOwnProperty").
5. ReturnIfAbrupt(trap).
6. If trap is undefined, then
   a. Return the result of calling the [[HasOwnProperty]] internal method of target with argument P.
7. Let trapResult be the result of calling the [[Call]] internal method of trap with handler as the this value and a new List containing target and P.
8. ReturnIfAbrupt(trapResult).
9. Let success be ToBoolean(trapResult).
10. If success is false, then
    a. Let targetDesc be the result of calling the [[GetOwnProperty]] internal method of target with argument P.
    b. ReturnIfAbrupt(targetDesc).
    c. If targetDesc is not undefined, then
       i. If targetDesc.[[Configurable]] is false, then throw a TypeError exception.
       ii. Let extensibleTarget be the result of calling the [[IsExtensible]] internal method of target.
       iii. ReturnIfAbrupt(extensibleTarget).
       iv. If ToBoolean(extensibleTarget) is false, then throw a TypeError exception.
11. Else success is true, then
    a. Let extensibleTarget be the result of IsExtensible(target).
    b. ReturnIfAbrupt(extensibleTarget).
    c. If ToBoolean(extensibleTarget) is true, then return success.
    d. Let targetDesc be the result of calling the [[GetOwnProperty]] internal method of target with argument P.
    e. ReturnIfAbrupt(targetDesc).
    f. If targetDesc is undefined, then throw a TypeError exception.
12. Return success.

NOTE [[HasOwnProperty]] for proxy objects enforces the following invariants:

- A property cannot be reported as non-existent, if it exists as a non-configurable own property of the target object.
- A property cannot be reported as non-existent, if it exists as a own property of the target object and the target object is not extensible.
- A property cannot be reported as exists, if it does not exists as a own property of the target object and the target object is not extensible.

9.3.6 [[GetOwnProperty]] (P)

When the [[GetOwnProperty]] internal method of an exotic Proxy object O is called with property key P, the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Let handler be the value of the [[ProxyHandler]] internal data property of O.
3. Let target be the value of the [[ProxyTarget]] internal data property of O.
4. Let trap be the result of GetMethod(handler, "getOwnPropertyDescriptor").
5. ReturnIfAbrupt(trap).
6. If trap is undefined, then
   a. Return the result of calling the [[GetOwnProperty]] internal method of target with argument P.
7. Let trapResultObj be the result of calling the [[Call]] internal method of trap with handler as the this value and a new List containing target and P.
8. ReturnIfAbrupt(trapResultObj).
9. If Type(trapResultObj) is neither Object or Undefined, then throw a TypeError exception.
10. Let targetDesc be the result of calling the [[GetOwnProperty]] internal method of target with argument P.
11. ReturnIfAbrupt(targetDesc).
12. If trapResultObj is undefined, then
   a. If targetDesc is undefined, then return undefined.
   b. If targetDesc.[[Configurable]] is false, then throw a TypeError exception.
   c. Let extensibleTarget be the result of IsExtensible(target).
   d. ReturnIfAbrupt(extensibleTarget).
   e. If ToBoolean(extensibleTarget) is false, then throw a TypeError exception.
   f. Return undefined.
13. Let extensibleTarget be the result of IsExtensible(target).
14. ReturnIfAbrupt(extensibleTarget).
15. Set extensibleTarget to ToBoolean(extensibleTarget).
16. Let resultDesc be ToPropertyDescriptor(trapResultObj).
17. ReturnIfAbrupt(resultDesc).
18. Call ComplexPropertyDescriptor(resultDesc, targetDesc).
19. Let valid be the result of IsCompatiblePropertyDescriptor (extensibleTarget, resultDesc, targetDesc).
20. If valid is false, then throw a TypeError exception.
21. If resultDesc.[[Configurable]] is false, then
   a. If targetDesc is undefined or targetDesc.[[Configurable]] is true, then
      a. Throw a TypeError exception.
22. Return resultDesc.

NOTE [[GetOwnProperty]] for proxy objects enforces the following invariants:

- The result of [[GetOwnProperty]] must be either an Object or undefined.
- A property cannot be reported as non-existent, if it exists as a non-configurable own property of the target object.
- A property cannot be reported as non-existent, if it exists as a own property of the target object and the target object is not extensible.
- A property cannot be reported as exists, if it does not exists as a own property of the target object and the target object is not extensible.
- A property cannot be reported as non-configurable, if it does not exists as a own property of the target object or if it exists as a configurable own property of the target object.
- The result of [[GetOwnProperty]] can be applied to the target object using [[DefineOwnProperty]] and will not throw an exception.

Commented [AWB1231]: Note the result descriptor defaults are set to the values in the targetDesc (if there is one) rather than the normal defaults. This is a change from the wiki spec.

Commented [AWB1232]: The resultDesc carries a reference to the original descriptor returned by the trap. A copy is not made and missing attribute properties are not added to it. This is a change from the wiki spec.
9.3.7 [[DefineOwnProperty]] (P, Desc)

When the [[DefineOwnProperty]] internal method of an exotic Proxy object O is called with property key P and property descriptor Desc, the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Let handler be the value of the [[ProxyHandler]] internal data property of O.
3. Let target be the value of the [[ProxyTarget]] internal data property of O.
4. Let trap be the result of GetMethod(handler, "defineProperty").
5. ReturnIfAbrupt(trap).
6. If trap is undefined, then
   a. Return the result of calling the [[DefineOwnProperty]] internal method of target with arguments P and Desc.
7. Let descObj be FromPropertyDescriptor(Desc).
8. NOTE If Desc was originally generated from an object using ToPropertyDescriptor, then descObj will be that original object.
9. Let trapResult be the result of calling the [[Call]] internal method of trap with handler as the this value and a new List containing target, P, and descObj.
10. ReturnIfAbrupt(trapResult).
11. If ToBoolean(trapResult) is false, then return false.
12. Let targetDesc be the result of calling the [[GetOwnProperty]] internal method of target with argument P.
13. ReturnIfAbrupt(targetDesc).
14. Let extensibleTarget be the result of IsExtensible(targetDesc).
15. ReturnIfAbrupt(extensibleTarget).
16. Set extensibleTarget to ToBoolean(extensibleTarget).
17. If Desc has a [[Configurable]] field and if Desc, [[Configurable]] is false, then
   a. Let settingConfigFalse be true.
18. Else let settingConfigFalse be false.
19. If targetDesc is undefined, then
   a. If extensibleTarget is false, then throw a TypeError exception.
20. Else targetDesc is not undefined.
   a. If IsCompatiblePropertyDescriptor(extensibleTarget, Desc, targetDesc) is false, then throw a TypeError exception.
   b. If settingConfigFalse is true and targetDesc, [[Configurable]] is true, then throw a TypeError exception.

NOTE [[DefineOwnProperty]] for proxy objects enforces the following invariants:
- A property cannot be added, if the target object is not extensible.
- A property cannot be added as or modified to be non-configurable, if it does not exists as a non-configurable own property of the target object.
- A property may not be non-configurable, if it corresponding configurable property of the target object exists.
- If a property has a corresponding target object property then apply the property descriptor of the property to the target object using [[DefineOwnProperty]] will not throw an exception.

9.3.8 [[HasProperty]] (P)

When the [[HasProperty]] internal method of an exotic Proxy object O is called with property key P, the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Let handler be the value of the [[ProxyHandler]] internal data property of O.
3. Let target be the value of the [[ProxyTarget]] internal data property of O.
4. Let trap be the result of GetMethod(handler, "has").
5. ReturnIfAbrupt(trap).
6. If trap is undefined, then
   a. Return the result of calling the [[HasProperty]] internal method of target with argument P.
7. Let trapResult be the result of calling the [[Call]] internal method of trap with handler as the this value and a new List containing target and P.
8. ReturnIfAbrupt(trapResult).
9. Let success be ToBoolean(trapResult).
10. If success is false, then
    a. Let targetDesc be the result of calling the [[GetOwnProperty]] internal method of target with argument P.
    b. ReturnIfAbrupt(targetDesc).
    c. If targetDesc is not undefined, then
       i. If targetDesc.[[Configurable]] is false, then throw a TypeError exception.
       ii. Let extensibleTarget be the result of IsExtensible(target).
       iii. ReturnIfAbrupt(extensibleTarget).
       iv. If ToBoolean(extensibleTarget) is false, then throw a TypeError exception.

NOTE [[HasProperty]] for proxy objects enforces the following invariants:
- A property cannot be reported as non-existent, if it exists as a non-configurable own property of the target object.
- A property cannot be reported as non-existent, if it exists as an own property of the target object and the target object is not extensible.

9.3.9 [[Get]] (P, Receiver)

When the [[Get]] internal method of an exotic Proxy object O is called with property key P and ECMAScript language value Receiver the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Let handler be the value of the [[ProxyHandler]] internal data property of O.
3. Let target be the value of the [[ProxyTarget]] internal data property of O.
4. Let trap be the result of GetMethod(handler, "get").
5. ReturnIfAbrupt(trap).
6. If trap is undefined, then
   a. Return the result of calling the [[Get]] internal method of target with arguments P and Receiver.
7. Let trapResult be the result of calling the [[Call]] internal method of trap with handler as the this value and a new List containing target, P, and Receiver.
8. ReturnIfAbrupt(trapResult).
9. Let targetDesc be the result of calling the [[GetOwnProperty]] internal method of target with argument P.
10. ReturnIfAbrupt(targetDesc).
11. If targetDesc is not undefined, then
    a. If IsDataDescriptor(targetDesc) and targetDesc.[[Configurable]] is false and targetDesc.[[Writable]] is false, then
       i. If SameValue(trapResult, targetDesc.[[Value]]) is false, then throw a TypeError exception.
    b. If IsAccessorDescriptor(targetDesc) and targetDesc.[[Configurable]] is false and targetDesc.[[Get]] is undefined, then
       i. If trapResult is not undefined, then throw a TypeError exception.
12. Return trapResult.

NOTE [[Get]] for proxy objects enforces the following invariants:
- The value reported for a property must be the same as the value of the corresponding target object property if the target object property is a non-writable, non-configurable data property.
- The value reported for a property must be undefined if the corresponding corresponding target object property is non-configurable accessor property that has undefined as its [[Get]] attribute.

9.3.10 [[Set]] (P, V, Receiver)

When the [[Set]] internal method of an exotic Proxy object O is called with property key P, value V, and ECMAScript language value Receiver, the following steps are taken:

1. Assert: IsPropertyKey(P) is true.
2. Let handler be the value of the [[ProxyHandler]] internal data property of O.
3. Let target be the value of the [[ProxyTarget]] internal data property of O.
4. Let trap be the result of GetMethod(handler, "set").
5. ReturnIfAbrupt(trap).
6. If `trap` is `undefined`, then
   a. Return the result of calling the `[[Set]]` internal method of `target` with arguments `P`, `V`, and `Receiver`.
7. Let `trapResult` be the result of calling the `[[Call]]` internal method of `trap` with `handler` as the `this` value and a new List containing `target`, `P`, `V`, and `Receiver`.
8. ReturnIfAbrupt(`trapResult`).
9. If `ToBoolean(trapResult)` is `false`, then return `false`.
10. Let `targetDesc` be the result of calling the `[[GetOwnProperty]]` internal method of `target` with argument `P`.
11. ReturnIfAbrupt(`targetDesc`).
12. If `targetDesc` is not `undefined`, then
   a. If `IsDataDescriptor(targetDesc)` and `targetDesc.[[Configurable]]` is `false` and `targetDesc.[[Writable]]` is `false`, then
      i. If `SameValue(V, targetDesc.[[Value]])` is `false`, then throw a `TypeError` exception.
   b. If `IsAccessorDescriptor(targetDesc)` and `targetDesc.[[Configurable]]` is `false`, then
      i. If `targetDesc.[[Set]]` is `undefined`, then throw a `TypeError` exception.
13. Return `true`.

**NOTE**  
`[[Set]]` for proxy objects enforces the following invariants:
- Cannot change the value of a property to be different from the value of the corresponding target object property if the corresponding target object property is a non-writable, non-configurable data property.
- Cannot set the value of a property if the corresponding corresponding target object property is a non-configurable accessor property that has `undefined` as its `[[Set]]` attribute.

### 9.3.11 `[[Invoke]]` (P, ArgumentsList, Receiver)

When the `[[Invoke]]` internal method of an exotic Proxy object `O` is called with property key `P`, List `ArgumentsList`, and ECMAScript language value `Receiver` the following steps are taken:

1. Assert: `IsPropertyKey(P)` is `true`.
2. Let `handler` be the value of the `[[ProxyHandler]]` internal data property of `O`.
3. Let `target` be the value of the `[[ProxyTarget]]` internal data property of `O`.
4. Let `trap` be the result of `GetMethod(handler, "invoke")`.
5. ReturnIfAbrupt(`trap`).
6. If `trap` is `undefined`, then
   a. Return the result of calling the `[[Call]]` internal method of `target` with arguments `P`, `ArgumentsList`, and `Receiver`.
7. Let `argArray` be the result of `CreateArrayFromList(ArgumentsList)`.
8. Return the result of calling the `[[Call]]` internal method of `trap` with `handler` as the `this` value and a new List containing `target`, `P`, `argArray`, and `Receiver`.

**NOTE**  
There are no invariants enforced for `[[Invoke]]`.

### 9.3.12 `[[Delete]]` (P)

When the `[[Delete]]` internal method of an exotic Proxy object `O` is called with property name `P` the following steps are taken:

1. Assert: `IsPropertyKey(P)` is `true`.
2. Let `handler` be the value of the `[[ProxyHandler]]` internal data property of `O`.
3. Let `target` be the value of the `[[ProxyTarget]]` internal data property of `O`.
4. Let `trap` be the result of `GetMethod(handler, "deleteProperty")`.
5. ReturnIfAbrupt(`trap`).
6. If `trap` is `undefined`, then
   a. Return the result of calling the `[[Delete]]` internal method of `target` with argument `P`.
7. Let `trapResult` be the result of calling the `[[Call]]` internal method of `trap` with `handler` as the `this` value and a new List containing `target` and `P`.
8. ReturnIfAbrupt(`trapResult`).
9. If `ToBoolean(trapResult)` is `false`, then return `false`.
10. Let `targetDesc` be the result of calling the `[[GetOwnProperty]]` internal method of `target` with argument `P`.
11. ReturnIfAbrupt(`targetDesc`).
12. If `targetDesc` is `undefined`, then return `true`.

© Ecma International 2013
13. If `targetDesc.[[Configurable]]` is `false`, then throw a `TypeError` exception.

NOTE [[Delete]] for proxy objects enforces the following invariant:
- A property cannot be deleted, if it exists as a non-configurable own property of the target object.

### 9.3.13 [[Enumerate]] ()

When the `[[Enumerate]]` internal method of an exotic Proxy object `O` is called the following steps are taken:

1. Let `handler` be the value of the `[[ProxyHandler]]` internal data property of `O`.
2. Let `target` be the value of the `[[ProxyTarget]]` internal data property of `O`.
3. Let `trap` be the result of `GetMethod(handler, "enumerate")`.
4. ReturnIfAbrupt(`trap`).
5. If `trap` is `undefined`, then
   a. Return the result of calling the `[[Enumerate]]` internal method of `target`.
6. Let `trapResult` be the result of calling the `[[Call]]` internal method of `trap` with `handler` as the this value and a new List containing `target`.
7. ReturnIfAbrupt(`trapResult`).
8. If Type(`trapResult`) is not `Object`, then throw a `TypeError` exception.
9. Return `trapResult`.

NOTE `[[Enumerate]]` for proxy objects enforces the following invariants:
- The result of `[[Enumerate]]` must be an `Object`.

### 9.3.14 [[OwnPropertyKeys]] ()

When the `[[OwnPropertyKeys]]` internal method of an exotic Proxy object `O` is called the following steps are taken:

1. Let `handler` be the value of the `[[ProxyHandler]]` internal data property of `O`.
2. Let `target` be the value of the `[[ProxyTarget]]` internal data property of `O`.
3. Let `trap` be the result of `GetMethod(handler, "ownKeys")`.
4. ReturnIfAbrupt(`trap`).
5. If `trap` is `undefined`, then
   a. Return the result of calling the `[[OwnPropertyKeys]]` internal method of `target`.
6. Let `trapResult` be the result of calling the `[[Call]]` internal method of `trap` with `handler` as the this value and a new List containing `target`.
7. ReturnIfAbrupt(`trapResult`).
8. If Type(`trapResult`) is not `Object`, then throw a `TypeError` exception.
9. Return `trapResult`.

NOTE `[[OwnPropertyKeys]]` for proxy objects enforces the following invariants:
- The result of `[[OwnPropertyKeys]]` must be an `Object`.

### 9.3.15 [[Call]] (thisArgument, argumentsList)

The `[[Call]]` internal method of an exotic Proxy object `O` is called with parameters `thisArgument` and `argumentsList`, a List of ECMAScript language values. The following steps are taken:

1. Let `handler` be the value of the `[[ProxyHandler]]` internal data property of `O`.
2. Let `target` be the value of the `[[ProxyTarget]]` internal data property of `O`.

Commented [AWB1233]: TODO.
Commented [AWB1234]: TODO
3. Let trap be the result of GetMethod(handler, "apply").
4. ReturnIfAbrupt(trap).
5. If trap is undefined, then
   a. Return the result of calling the [[Call]] internal method of target with arguments thisArgument and
      argumentsList.
6. Let argArray be the result of CreateArrayFromList(argumentsList).
7. Return the result of calling the [[Call]] internal method of trap with handler as the this value and a new List
      containing target, thisArgument, and argArray.

NOTE 1 An Proxy exotic object only has a [[Call]] internal method if the initial value of its [[ProxyTarget]] internal data
property is an object that has a [[Call]] internal method.

9.3.16 [[Construct]] Internal Method

The [[Construct]] internal method of an exotic Proxy object O is called with a single parameter argumentsList which is a possibly empty List of ECMAScript language values. The following steps are taken:

1. Let handler be the value of the [[ProxyHandler]] internal data property of O.
2. Let target be the value of the [[ProxyTarget]] internal data property of O.
3. Let trap be the result of GetMethod(handler, "construct").
4. ReturnIfAbrupt(trap).
5. If trap is undefined, then
   a. Return the result of calling the [[Construct]] internal method of target with argument argumentsList.
6. Let newObject be the result of CreateArrayFromList(argumentsList).
7. Let newObj be the result of calling trap with handler as the this value and a new List containing target and
   argArray.
8. ReturnIfAbrupt(newObj).
9. If Type(newObj) is not Object, then throw a TypeError exception.
10. Return newObj.

NOTE 2 [[Construct]] for proxy objects enforces the following invariants:
   • The result of [[Construct]] must be an Object.

10 ECMAScript Language: Source Code

Syntax

SourceCharacter ::
   any Unicode character

The ECMAScript code is expressed using Unicode, version 5.1 or later. ECMAScript source text is a sequence of Unicode characters. The phrase “Unicode character” refers to the abstract linguistic or typographical unit represented by a single Unicode scalar value. The actual encodings used to store and interchange ECMAScript source text is not relevant to this specification. Any well-defined encoding such as UTF-32 or UTF-16 may be used. Source text might even be externally represented using a non-Unicde character encoding. Regardless of the external source text encoding, a conforming ECMAScript implementation processes the source text as if it was an equivalent sequence of SourceCharacter values. Each SourceCharacter being an abstract Unicode character with a corresponding Unicode scalar value. Conforming ECMAScript implementations are not required to perform any normalisation of text, or behave as though they were performing normalisation of text.

The phrase “code point” refers to such a Unicode scalar value. “Unicode character” only refers to entities represented by single Unicode scalar values: the components of a combining character sequence are still individual “Unicode characters,” even though a user might think of the whole sequence as a single character.

In string literals, regular expression literals, template literals and identifiers, any Unicode characters may also be expressed as a Unicode escape sequence that explicitly express a code point’s numeric value. Within a
comment, such an escape sequence is effectively ignored as part of the comment. Within other contexts, such an escape sequence contextually contributes one Unicode character.

NOTE  ECMAScript differs from the Java programming language in the behaviour of Unicode escape sequences. In a Java program, if the Unicode escape sequence \\u000A, for example, occurs within a single-line comment, it is interpreted as a line terminator (Unicode character 000A is line feed) and therefore the next Unicode character is not part of the comment. Similarly, if the Unicode escape sequence \\u000A occurs within a string literal in a Java program, it is likewise interpreted as a line terminator, which is not allowed within a string literal—one must write \\n instead of \\u000A to cause a line feed to be part of the string value of a string literal. In an ECMAScript program, a Unicode escape sequence occurring within a comment is never interpreted and therefore cannot contribute to termination of the comment. Similarly, a Unicode escape sequence occurring within a string literal in an ECMAScript program always contributes a Unicode character to the literal and is never interpreted as a line terminator or as a quote mark that might terminate the string literal.

ECMAScript String values (6.1.4) are computational sequences of 16-bit integer values called “code units”. ECMAScript language constructs that generate string values from SourceCharacter sequences use UTF-16 encoding to generate the code unit values.

**Static Semantics: UTF-16 Encoding**

The UTF-16 Encoding of a numeric code point value, cp, is determined as follows:

1. \(\text{Assert: } 0 \leq \text{cp} \leq 0x10FFFF\)
2. If \(\text{cp} \leq 65535\), then return \(\text{cp}\).
3. Let \(cu1\) be \(\text{floor}((\text{cp} - 65536) / 1024) + 55296.\) NOTE 55296 is 0xD800.
4. Let \(cu2\) be \((\text{cp} - 65536) \mod 1024\) + 56320. NOTE 56320 is 0xDC00.
5. Return the code unit sequence consisting of \(cu1\) followed by \(cu2\).

**10.1 Types of Executable Code**

There are four types of ECMAScript code:

- **Global code** is source text that is treated as an ECMAScript Script. The global code of a particular Script does not include any source text that is parsed as part of a FunctionBody, GeneratorBody, ConciseBody, ClassBody, or ModuleBody.

- **Eval code** is the source text supplied to the built-in `eval` function. More precisely, if the parameter to the built-in `eval` function is a String, it is treated as an ECMAScript Script. The eval code for a particular invocation of `eval` is the global code portion of that Script.

- **Function code** is source text that is parsed to supply the value of the `[[Code]]` internal data property (see 9.1.16) of function and generator objects. The function code of a particular function or generator does not include any source text that is parsed as the function code of a nested FunctionBody, GeneratorBody, ConciseBody, or ClassBody.

- **Module code** is source text that is code that is provided as a ModuleBody. It is the code that is directly evaluated when a module is initialised. The module code of a particular module does not include any source text that is parsed as part of a nested FunctionBody, GeneratorBody, ConciseBody, ClassBody, or ModuleBody.

**Remark** Function code is generally provided as the bodies of Function Definitions (14.1), Arrow Function Definitions (14.2), Method Definitions (14.3) and Generator Definitions (14.4). Function code is also derived from the last argument to the Function constructor (19.2.1.1) and the GeneratorFunction constructor (25.3.1.1).

**10.1.1 Strict Mode Code**

An ECMAScript Script syntactic unit may be processed using either unrestricted or strict mode syntax and semantics. When processed using strict mode the four types of ECMAScript code are referred to as module code, strict global code, strict eval code, and strict function code. Code is interpreted as strict mode code in the following situations:
Global code is strict global code if it begins with a Directive Prologue that contains a Use Strict Directive (see 15.2).

Module code is always strict code.

A `ClassDeclaration` or a `ClassExpression` is always strict code.

Eval code is strict eval code if it begins with a Directive Prologue that contains a Use Strict Directive or if the call to eval is a direct call (see 18.2.1) to the eval function that is contained in strict mode code.

Function code that is part of a `FunctionDeclaration`, `FunctionExpression`, or accessor `PropertyDefinition` is strict function code if its `FunctionDeclaration`, `FunctionExpression`, or `PropertyDefinition` is contained in strict mode code or if the function code begins with a Directive Prologue that contains a Use Strict Directive.

Function code that is supplied as the last argument to the built-in `Function` constructor is strict function code if the last argument is a String that when processed as a `FunctionBody` begins with a Directive Prologue that contains a Use Strict Directive.

10.1.2 Non-ECMAScript Functions

An ECMAScript implementation may support the evaluation of function objects whose evaluative behaviour is expressed in some implementation defined form of executable code other than via ECMAScript code. Whether a function object is an ECMAScript code function or a non-ECMAScript function is not semantically observable from the perspective of an ECMAScript code function that calls or is called by such a non-ECMAScript function.

11 ECMAScript Language: Lexical Grammar

The source text of an ECMAScript script is first converted into a sequence of input elements, which are tokens, line terminators, comments, or white space. The source text is scanned from left to right, repeatedly taking the longest possible sequence of characters as the next input element.

There are several situations where the identification of lexical input elements is sensitive to the syntactic grammar context that is consuming the input elements. This requires multiple goal symbols for the lexical grammar. The `InputElementDiv` goal symbol is the default goal symbol and is used in those syntactic grammar contexts where a leading division (/) or division-assignment (/=) operator is permitted. The `InputElementRegExp` goal symbol is used in all syntactic grammar contexts where a `RegularExpressionLiteral` is permitted. The `InputElementTemplateTail` goal is used in syntactic grammar contexts where a `TemplateLiteral` logically continues after a substitution element.

NOTE There are no syntactic grammar contexts where both a leading division or division-assignment, and a leading `RegularExpressionLiteral` are permitted. This is not affected by semicolon insertion (see 11.9); in examples such as the following:

```
a = b / hi/g.exec(c).map(d);
```

where the first non-whitespace, non-comment character after a `LineTerminator` is slash (/) and the syntactic context allows division or division-assignment, no semicolon is inserted at the `LineTerminator`. That is, the above example is interpreted in the same way as:

```
a = b / hi / g.exec(c).map(d);
```
Syntax

InputElementDiv ::
  Whitespace
  LineTerminator
  Comment
  Token
  DivPunctuator
  RightBracePunctuator

InputElementRegExp ::
  Whitespace
  LineTerminator
  Comment
  Token
  RightBracePunctuator
  RegularExpressionLiteral

InputElementTemplateTail ::
  Whitespace
  LineTerminator
  Comment
  Token
  DivPunctuator
  TemplateSubstitutionTail

11.1 Unicode Format-Control Characters

The Unicode format-control characters (i.e., the characters in category "CF" in the Unicode Character Database such as LEFT-TO-RIGHT MARK or RIGHT-TO-LEFT MARK) are control codes used to control the formatting of a range of text in the absence of higher-level protocols for this (such as mark-up languages).

It is useful to allow format-control characters in source text to facilitate editing and display. All format control characters may be used within comments, and within string literals, template literals, and regular expression literals.

&lt;ZWJ&gt; and &lt;ZWNJ&gt; are format-control characters that are used to make necessary distinctions when forming words or phrases in certain languages. In ECMAScript source text, &lt;ZWJ&gt; and &lt;ZWNJ&gt; may also be used in an identifier after the first character.

&lt;BOM&gt; is a format-control character used primarily at the start of a text to mark it as Unicode and to allow detection of the text's encoding and byte order. &lt;BOM&gt; characters intended for this purpose can sometimes also appear after the start of a text, for example as a result of concatenating files. &lt;BOM&gt; characters are treated as white space characters (see 11.2).

The special treatment of certain format-control characters outside of comments, string literals, and regular expression literals is summarised in Table 27.

<table>
<thead>
<tr>
<th>Code Point</th>
<th>Name</th>
<th>Formal Name</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>U+200C</td>
<td>Zero width non-joiner</td>
<td>&lt;ZWNJ&gt;</td>
<td>IdentifierPart</td>
</tr>
<tr>
<td>U+200D</td>
<td>Zero width joiner</td>
<td>&lt;ZWJ&gt;</td>
<td>IdentifierPart</td>
</tr>
<tr>
<td>U+FEFF</td>
<td>Byte Order Mark</td>
<td>&lt;BOM&gt;</td>
<td>Whitespace</td>
</tr>
</tbody>
</table>

Table 27 — Format-Control Character Usage
11.2 White Space

White space characters are used to improve source text readability and to separate tokens (indivisible lexical units) from each other, but are otherwise insignificant. White space characters may occur between any two tokens and at the start or end of input. White space characters may occur within a StringLiteral, a RegularExpressionLiteral, a Template, or a TemplateSubstitutionTail where they are considered significant characters forming part of a literal value. They may also occur within a Comment, but cannot appear within any other kind of token.

The ECMAScript white space characters are listed in Table 28.

<table>
<thead>
<tr>
<th>Code Point</th>
<th>Name</th>
<th>Formal Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>U+0009</td>
<td>Tab</td>
<td>&lt;TAB&gt;</td>
</tr>
<tr>
<td>U+000B</td>
<td>Vertical Tab</td>
<td>&lt;VT&gt;</td>
</tr>
<tr>
<td>U+000C</td>
<td>Form Feed</td>
<td>&lt;FF&gt;</td>
</tr>
<tr>
<td>U+0020</td>
<td>Space</td>
<td>&lt;SP&gt;</td>
</tr>
<tr>
<td>U+00A0</td>
<td>No-break space</td>
<td>&lt;NBSP&gt;</td>
</tr>
<tr>
<td>U+FFFE</td>
<td>Byte Order Mark</td>
<td>&lt;BOM&gt;</td>
</tr>
<tr>
<td>Other category “Zs”</td>
<td>Any other Unicode</td>
<td>&lt;USP&gt;</td>
</tr>
</tbody>
</table>

ECMAScript implementations must recognise all of the white space characters defined in Unicode 5.1. Later editions of the Unicode Standard may define other white space characters. ECMAScript implementations may recognise white space characters from later editions of the Unicode Standard.

Syntax

WhiteSpace ::=
<TAB>
<VT>
<FF>
<SP>
<NBSP>
<BOM>
<USP>

11.3 Line Terminators

Like white space characters, line terminator characters are used to improve source text readability and to separate tokens (indivisible lexical units) from each other. However, unlike white space characters, line terminators have some influence over the behaviour of the syntactic grammar. In general, line terminators may occur between any two tokens, but there are a few places where they are forbidden by the syntactic grammar. Line terminators also affect the process of automatic semicolon insertion (11.9). A line terminator cannot occur within any token except a StringLiteral, Template, or TemplateSubstitutionTail. Line terminators may only occur within a StringLiteral token as part of a LineContinuation.

A line terminator can occur within a MultiLineComment (11.4) but cannot occur within a SingleLineComment.

Line terminators are included in the set of white space characters that are matched by the \s class in regular expressions.

The ECMAScript line terminator characters are listed in Table 29.
Table 29 — Line Terminator Characters

<table>
<thead>
<tr>
<th>Code Point</th>
<th>Name</th>
<th>Formal Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>U+000A</td>
<td>Line Feed</td>
<td>&lt;LF&gt;</td>
</tr>
<tr>
<td>U+000D</td>
<td>Carriage Return</td>
<td>&lt;CR&gt;</td>
</tr>
<tr>
<td>U+2028</td>
<td>Line separator</td>
<td>&lt;LS&gt;</td>
</tr>
<tr>
<td>U+2029</td>
<td>Paragraph separator</td>
<td>&lt;PS&gt;</td>
</tr>
</tbody>
</table>

Only the Unicode characters in Table 29 are treated as line terminators. Other new line or line breaking Unicode characters are treated as white space but not as line terminators. The sequence <CR><LF> is commonly used as a line terminator. It should be considered a single SourceCharacter for the purpose of reporting line numbers.

Syntax

\[\text{Line Terminator} :: \]
\[<\text{LF}> \]
\[<\text{CR}> \]
\[<\text{LS}> \]
\[<\text{PS}> \]

\[\text{Line Terminator Sequence} :: \]
\[<\text{LF}> \]
\[<\text{CR}> \text{ lookahead } <\text{LF}> ]\]
\[<\text{LS}> \]
\[<\text{PS}> \]
\[<\text{CR}> <\text{LF}> \]

11.4 Comments

Comments can be either single or multi-line. Multi-line comments cannot nest.

Because a single-line comment can contain any Unicode character except a Line Terminator character, and because of the general rule that a token is always as long as possible, a single-line comment always consists of all characters from the // marker to the end of the line. However, the Line Terminator at the end of the line is not considered to be part of the single-line comment; it is recognised separately by the lexical grammar and becomes part of the stream of input elements for the syntactic grammar. This point is very important, because it implies that the presence or absence of single-line comments does not affect the process of automatic semicolon insertion (see 11.9).

Comments behave like white space and are discarded except that, if a MultiLineComment contains a line terminator character, then the entire comment is considered to be a Line Terminator for purposes of parsing by the syntactic grammar.

Syntax

\[\text{Comment} :: \]
\[\text{MultiLineComment} \]
\[\text{SingleLineComment} \]

\[\text{MultiLineComment} :: \]
\[/ * \text{MultiLineCommentChars}\text{opt} */ \]

\[\text{MultiLineCommentChars} :: \]
\[\text{MultiLineNotAsteriskChar MultiLineCommentChars}\text{opt} \]
\[* \text{PostAsteriskCommentChars}\text{opt} \]

\[\text{PostAsteriskCommentChars} :: \]
\[\text{MultiLineNotForwardSlashOrAsteriskChar MultiLineCommentChars}\text{opt} \]
\[* \text{PostAsteriskCommentChars}\text{opt} \]
MultiLineNotAsteriskChar ::
SourceCharacter but not *

MultiLineNotForwardSlashOrAsteriskChar ::
SourceCharacter but not one of / or *

SingleLineComment ::
  // SingleLineCommentChars

SingleLineCommentChars ::
  SingleLineCommentChar SingleLineCommentChars

SingleLineCommentChar ::
  SourceCharacter but not LineTerminator

11.5 Tokens

Syntax

Token ::
  IdentifierName
  Punctuator
  NumericLiteral
  StringLiteral
  Template

NOTE The DivPunctuator, RegularExpressionLiteral, RightBracePunctuator, and TemplateSubstitutionTail productions define tokens, but are not included in the Token production.

11.6 Identifier Names and Identifiers

IdentifierName, Identifier, and ReservedWord are tokens that are interpreted according to the Default Identifier Syntax given in Unicode Standard Annex #31, Identifier and Pattern Syntax, with some small modifications. ReservedWord is an enumerated subset of IdentifierName and Identifier is an IdentifierName that is not a ReservedWord (see 11.6.1). The Unicode identifier grammar is based on character properties specified by the Unicode Standard. The Unicode characters in the specified categories in version 5.1.0 of the Unicode standard must be treated as in those categories by all conforming ECMAScript implementations. ECMAScript implementations may recognize identifier characters defined in later editions of the Unicode Standard.

NOTE 1 This standard specifies specific character additions: The dollar sign (U+0024) and the underscore (U+005F) are permitted anywhere in an IdentifierName, and the characters zero width non-joiner (U+200C) and zero width joiner (U+200D) are permitted anywhere after the first character of an IdentifierName.

Unicode escape sequences are permitted in an IdentifierName, where they contribute a single Unicode character to the IdentifierName. The code point of the contributed character is expressed by the HexDigits of the UnicodeEscapeSequence (see 11.8.4). The \ preceding the UnicodeEscapeSequence and the \ and ( ) characters, if they appear, do not contribute characters to the IdentifierName. A UnicodeEscapeSequence cannot be used to put a character into an IdentifierName that would otherwise be illegal. In other words, if a UnicodeEscapeSequence sequence were replaced by the Unicode character it contributes, the result must still be a valid IdentifierName that has the exact same sequence of characters as the original IdentifierName. All interpretations of IdentifierName within this specification are based upon their actual characters regardless of whether or not an escape sequence was used to contribute any particular characters.

Two IdentifierName that are canonically equivalent according to the Unicode standard are not equal unless they are represented by the exact same sequence of code units (in other words, conforming ECMAScript implementations are only required to do bitwise comparison on IdentifierName values).

NOTE 2 If maximal portability is a concern, programmers should only employ the identifier characters that were defined in Unicode 3.0.

Commented [AWB939]: Norbert suggests changing this to 5.1.0. Would be really be better for “portability”?
**Syntax**

Identifier ::

IdentifierName but not ReservedWord

IdentifierName ::

IdentifierStart

IdentifierName IdentifierPart

IdentifierStart ::

UnicodeIDStart

$ UnicodeEscapeSequence

IdentifierPart ::

UnicodeIDContinue

$ UnicodeEscapeSequence

<ZWNJ>

<ZWJ>

UnicodeIDStart :: any Unicode character with the Unicode property "ID_Start".

UnicodeIDContinue :: any Unicode character with the Unicode property "ID_Continue".

The definitions of the nonterminal UnicodeEscapeSequence is given in 11.8.4.

**Static Semantics: String Value**

Identifier :: IdentifierName but not ReservedWord

1. Return the StringValue of IdentifierName.

IdentifierName ::

IdentifierStart

IdentifierName IdentifierPart

1. Return the String value consisting of the sequence of code units corresponding to IdentifierName. In determining the sequence any occurrences of UnicodeEscapeSequence are first replaced with the code point represented by the UnicodeEscapeSequence and then the code points of the entire IdentifierName are converted to code units by UTF-16 Encoding (clause 10) each code point.

**11.6.1 Reserved Words**

A reserved word is an IdentifierName that cannot be used as an Identifier.

**Syntax**

ReservedWord ::

Keyword

FutureReservedWord

NullLiteral

BooleanLiteral

The ReservedWord definitions are specified as literal sequences of Unicode characters. However, any Unicode character in a ReservedWord can also be expressed by a UnicodeEscapeSequence that expresses that same
Unicode character's code point. Use of such escape sequences does not change the meaning of the ReservedWord.

### 11.6.1.1 Keywords

The following tokens are ECMAScript keywords and may not be used as Identifiers in ECMAScript programs.

#### Syntax

Keyword :: one of

- `break`
- `delete`
- `import`
- `this`
- `case`
- `do`
- `in`
- `throw`
- `catch`
- `else`
- `instanceof`
- `try`
- `class`
- `export`
- `let`
- `typeof`
- `continue`
- `finally`
- `new`
- `var`
- `const`
- `for`
- `return`
- `void`
- `debugger`
- `function`
- `super`
- `while`
- `default`
- `if`
- `switch`
- `with`

### 11.6.1.2 Future Reserved Words

The following words are used as keywords in proposed extensions and are therefore reserved to allow for the possibility of future adoption of those extensions.

#### Syntax

FutureReservedWord :: one of

- `enum`
- `extends`

The following tokens are also considered to be FutureReservedWords when they occur within strict mode code (see 10.1.1). The occurrence of any of these tokens within strict mode code in any context where the occurrence of a FutureReservedWord would produce an error must also produce an equivalent error:

- `implements`
- `private`
- `public`
- `yield`
- `interface`
- `package`
- `protected`
- `static`
11.7 Punctuators

Syntax

Punctuator :: one of

{ } [ ] . . . . ; , < > <= >= += -= *= % = += -= <<= >>= >>>& ^ ! ~ && || ? : != !== !==

DivPunctuator :: one of

/ /=

RightBracePunctuator :: 

}

11.8 Literals

11.8.1 Null Literals

Syntax

NullLiteral ::

null

11.8.2 Boolean Literals

Syntax

BooleanLiteral ::

true false

11.8.3 Numeric Literals

Syntax

NumericLiteral ::

DecimalLiteral BinaryIntegerLiteral OctalIntegerLiteral HexIntegerLiteral

DecimalLiteral ::

DecimalDigits . DecimalDigits ExponentPart opt

. DecimalDigits ExponentPart opt

DecimalIntegerLiteral ExponentPart opt

DecimalIntegerLiteral ::

0 NonZeroDigit DecimalDigits

DecimalDigits ::

DecimalDigit DecimalDigits DecimalDigit

Commented [AWB742]: From March 29 meeting notes:

Hex floating point literals:
Waldemar: Other languages include these things. They’re rarely used but when you want one, you really want one. Use cases are similar to that of hex literals. Will explore adding them.
MarkM: 0x3.p1 currently evaluates to undefined. This would be a breaking change.
Waldemar: Not clear anyone would notice. How did other languages deal with this?
DecimalDigit :: one of
  0 1 2 3 4 5 6 7 8 9

NonZeroDigit :: one of
  1 2 3 4 5 6 7 8 9

ExponentPart ::
  ExponentIndicator SignedInteger

ExponentIndicator :: one of
  e E

SignedInteger ::

  0x HexDigit
  0X HexDigit

HexDigit ::
  HexDigit
  HexDigits HexDigit

Hex ::
  one of
  0 1 2 3 4 5 6 7 8 9 a b c d e f A B C D E F

The SourceCharacter immediately following a NumericLiteral must not be an IdentifierStart or DecimalDigit.

NOTE For example:

`3in` is an error and not the two input elements 3 and in.

A conforming implementation, when processing strict mode code (see 10.1.1), must not extend the syntax of NumericLiteral to include LegacyOctalIntegerLiteral as described in B.1.1.
Static Semantics: MV's

A numeric literal stands for a value of the Number type. This value is determined in two steps: first, a mathematical value (MV) is derived from the literal; second, this mathematical value is rounded as described below.

- The MV of NumericLiteral :: DecimalLiteral is the MV of DecimalLiteral.
- The MV of NumericLiteral :: BinaryIntegerLiteral is the MV of BinaryIntegerLiteral.
- The MV of NumericLiteral :: OctalIntegerLiteral is the MV of OctalIntegerLiteral.
- The MV of NumericLiteral :: HexIntegerLiteral is the MV of HexIntegerLiteral.
- The MV of DecimalLiteral :: DecimalIntegerLiteral. is the MV of DecimalIntegerLiteral.
- The MV of DecimalLiteral :: DecimalDigits is the MV of DecimalIntegerLiteral plus (the MV of DecimalDigits × 10ⁿ), where n is the number of characters in DecimalDigits.
- The MV of DecimalLiteral :: DecimalDigits ExponentPart is the MV of DecimalIntegerLiteral × 10ⁿ, where e is the MV of ExponentPart.
- The MV of DecimalLiteral :: DecimalIntegerLiteral. , DecimalDigits ExponentPart is (the MV of DecimalIntegerLiteral plus (the MV of DecimalDigits × 10ⁿ)) × 10ⁿ, where n is the number of characters in DecimalDigits and e is the MV of ExponentPart.
- The MV of DecimalLiteral :: DecimalDigits is the MV of DecimalDigits × 10ⁿ, where n is the number of characters in DecimalDigits.
- The MV of DecimalLiteral :: DecimalDigits ExponentPart is the MV of DecimalDigits × 10ⁿ, where n is the number of characters in DecimalDigits and e is the MV of ExponentPart.
- The MV of DecimalLiteral :: DecimalIntegerLiteral is the MV of DecimalIntegerLiteral.
- The MV of DecimalLiteral :: DecimalIntegerLiteral. ExponentPart is the MV of DecimalIntegerLiteral × 10ⁿ, where e is the MV of ExponentPart.
- The MV of DecimalIntegerLiteral :: 0 is 0.
- The MV of DecimalIntegerLiteral :: NonZeroDigit is the MV of NonZeroDigit.
- The MV of DecimalIntegerLiteral :: NonZeroDigit DecimalDigits is (the MV of NonZeroDigits) plus the MV of DecimalDigits, where n is the number of characters in DecimalDigits.
- The MV of DecimalDigits :: DecimalDigit is the MV of DecimalDigit.
- The MV of DecimalDigits :: DecimalDigit ExponentPart is the MV of DecimalDigit × 10ⁿ plus the MV of DecimalDigit.
- The MV of ExponentPart :: ExponentIndicator SignedInteger is the MV of SignedInteger.
- The MV of SignedInteger :: DecimalDigits is the MV of DecimalDigits.
- The MV of SignedInteger :: DecimalDigits is the MV of DecimalDigits.
- The MV of SignedInteger :: - DecimalDigits is the negative of the MV of DecimalDigits.
- The MV of DecimalDigit :: 0 or of HexDigit :: 0 or of OctalDigit :: 0 or of BinaryDigit :: 0 is 0.
- The MV of DecimalDigit :: 1 or of NonZeroDigit :: 1 or of HexDigit :: 1 or of OctalDigit :: 1 or of BinaryDigit :: 1 is 1.
- The MV of DecimalDigit :: 2 or of NonZeroDigit :: 2 or of HexDigit :: 2 or of OctalDigit :: 2 is 2.
- The MV of DecimalDigit :: 3 or of NonZeroDigit :: 3 or of HexDigit :: 3 or of OctalDigit :: 3 is 3.
- The MV of DecimalDigit :: 4 or of NonZeroDigit :: 4 or of HexDigit :: 4 or of OctalDigit :: 4 is 4.
- The MV of DecimalDigit :: 5 or of NonZeroDigit :: 5 or of HexDigit :: 5 or of OctalDigit :: 5 is 5.
- The MV of DecimalDigit :: 6 or of NonZeroDigit :: 6 or of HexDigit :: 6 or of OctalDigit :: 6 is 6.
- The MV of DecimalDigit :: 7 or of NonZeroDigit :: 7 or of HexDigit :: 7 or of OctalDigit :: 7 is 7.
- The MV of DecimalDigit :: 8 or of NonZeroDigit :: 8 or of HexDigit :: 8 is 8.
- The MV of DecimalDigit :: 9 or of NonZeroDigit :: 9 or of HexDigit :: 9 is 9.
- The MV of HexDigit :: a or of HexDigit :: A is 10.
- The MV of HexDigit :: b or of HexDigit :: B is 11.
- The MV of HexDigit :: c or of HexDigit :: C is 12.
- The MV of HexDigit :: d or of HexDigit :: D is 13.
- The MV of HexDigit :: e or of HexDigit :: E is 14.
- The MV of HexDigit :: f or of HexDigit :: F is 15.

© Ecma International 2013
- The MV of `BinaryIntegerLiteral :: 0b BinaryDigits` is the MV of `BinaryDigits`.
- The MV of `BinaryIntegerLiteral :: 0B BinaryDigits` is the MV of `BinaryDigits`.
- The MV of `BinaryDigits :: BinaryDigits BinaryDigit` is (the MV of `BinaryDigits` × 2) plus the MV of `BinaryDigit`.
- The MV of `OctalIntegerLiteral :: 0o OctalDigits` is the MV of `OctalDigits`.
- The MV of `OctalIntegerLiteral :: 0O OctalDigits` is the MV of `OctalDigits`.
- The MV of `OctalDigits :: OctalDigit` is the MV of `OctalDigit`.
- The MV of `OctalDigits :: OctalDigits OctalDigit` is (the MV of `OctalDigits` × 8) plus the MV of `OctalDigit`.
- The MV of `HexIntegerLiteral :: 0x HexDigits` is the MV of `HexDigits`.
- The MV of `HexIntegerLiteral :: 0X HexDigits` is the MV of `HexDigits`.
- The MV of `HexDigits :: HexDigit` is the MV of `HexDigit`.
- The MV of `HexDigits :: HexDigits HexDigit` is (the MV of `HexDigits` × 16) plus the MV of `HexDigit`.

Once the exact MV for a numeric literal has been determined, it is then rounded to a value of the `Number` type. If the MV is 0, then the rounded value is `+0`; otherwise, the rounded value must be the `Number` value for the MV (as specified in 6.1.5), unless the literal is a `DecimalLiteral` and the literal has more than 20 significant digits, in which case the `Number` value may be either the `Number` value for the MV of a literal produced by replacing each significant digit after the 20th with a `0` digit or the `Number` value for the MV of a literal produced by replacing each significant digit after the 20th with a `0` digit and then incrementing the literal at the 20th significant digit position. A digit is significant if it is not part of an `ExponentPart` and
- it is not `0`; or
- there is a nonzero digit to its left and there is a nonzero digit, not in the `ExponentPart`, to its right.

### 11.8.4 String Literals

NOTE A string literal is zero or more Unicode code points enclosed in single or double quotes. Unicode code points may also be represented by an escape sequence. All characters may appear literally in a string literal except for the closing quote character, backslash, carriage return, line separator, paragraph separator, and line feed. Any character may appear in the form of an escape sequence. String literals evaluate to ECAMScript `String` values. When generating these string values Unicode code points are UTF-16 encoded as defined in clause 6. Code points belonging to Basic Multilingual Plane are encoded as a single code unit element of the string. All other code points are encoded as two code unit elements of the string.

**Syntax**

```
StringLiteral ::
  " DoubleStringCharactersopt "
  ' SingleStringCharactersopt '

DoubleStringCharacters ::
  DoubleStringCharacter DoubleStringCharactersopt

SingleStringCharacters ::
  SingleStringCharacter SingleStringCharactersopt

DoubleStringCharacter ::
  SourceCharacter but not one of " or \ or LineTerminator
  \ EscapeSequence
  LineContinuation

SingleStringCharacter ::
  SourceCharacter but not one of ' or \ or LineTerminator
  \ EscapeSequence
  LineContinuation
```
A conforming implementation, when processing strict mode code (see 10.1.1), must not extend the syntax of `EscapeSequence` to include `LegacyOctalEscapeSequence` as described in 8.1.2.

CharacterEscapeSequence ::
  SingleEscapeCharacter
  NonEscapeCharacter

SingleEscapeCharacter :: one of`
  " \ b f n r t v

NonEscapeCharacter :: `SourceCharacter` but not one of `EscapeCharacter` or `LineTerminator`

EscapeCharacter ::
  SingleEscapeCharacter
  DecimalDigit
  x
  u

HexEscapeSequence ::
  x HexDigit HexDigit

UnicodeEscapeSequence ::
  u HexDigit HexDigit HexDigit
  u{ HexDigit }

The definition of the nonterminal `HexDigit` is given in 11.8.3. `SourceCharacter` is defined in clause 10.

NOTE A line terminator character cannot appear in a string literal, except as part of a `LineContinuation` to produce the empty character sequence. The correct way to cause a line terminator character to be part of the String value of a string literal is to use an escape sequence such as `\n` or `\u000A`.

Static Semantics

Static Semantics: Early Errors

UnicodeEscapeSequence :: `u{ HexDigits }`

- It is a Syntax Error if the MV of `HexDigits` > 1114111.

Static Semantics: SV’s and CV’s

A string literal stands for a value of the String type. The String value (SV) of the literal is described in terms of code unit values (CV) contributed by the various parts of the string literal. As part of this process, some Unicode characters within the string literal are interpreted as having a mathematical value (MV), as described below or in 11.8.3.

- The SV of `StringLiteral :: " "` is the empty code unit sequence.
- The SV of `StringLiteral :: " "` is the empty code unit sequence.
- The SV of `StringLiteral :: " DoubleStringCharacters "` is the SV of `DoubleStringCharacters`.

Commented [AWB1844]: Need to make a x-ref
• The SV of SingleStringLiteral :: 'SingleStringCharacters' * is the SV of SingleStringCharacters.
• The SV of DoubleStringCharacters :: DoubleStringCharacter is a sequence of one or two code units that is the CV of DoubleStringCharacter.
• The SV of DoubleStringCharacters :: DoubleStringCharacter DoubleStringCharacters is a sequence of one or two code units that is the CV of DoubleStringCharacter followed by all the code units in the SV of DoubleStringCharacters in order.
• The SV of SingleStringCharacters :: SingleStringCharacter is a sequence of one or two code units that is the CV of SingleStringCharacter.
• The SV of LineContinuation :: \ LineTerminatorSequence is the empty code unit sequence.
• The CV of DoubleStringCharacter :: SourceCharacter but not one of " or \ or LineTerminator is the UTF-16 Encoding (clause 6) of the code point value of SourceCharacter.
• The CV of DoubleStringCharacter :: \ EscapeSequence is the CV of the EscapeSequence.
• The CV of DoubleStringCharacter :: LineContinuation is the empty character sequence.
• The CV of SingleStringCharacter :: SourceCharacter but not one of " or \ or LineTerminator is the UTF-16 Encoding (clause 6) of the code point value of SourceCharacter.
• The CV of SingleStringCharacter :: \ EscapeSequence is the CV of the EscapeSequence.
• The CV of SingleStringCharacter :: LineContinuation is the empty character sequence.
• The CV of EscapeSequence :: CharacterEscapeSequence is the CV of the CharacterEscapeSequence.
• The CV of EscapeSequence :: 0 [notahead $DecimalDigit] is the code unit value 0.
• The CV of EscapeSequence :: HexEscapeSequence is the CV of the HexEscapeSequence.
• The CV of EscapeSequence :: UnicodeEscapeSequence is the CV of the UnicodeEscapeSequence.
• The CV of CharacterEscapeSequence :: SingleEscapeCharacter is the character whose code unit value is determined by the SingleEscapeCharacter according to Table 30.

</table>

The CV of CharacterEscapeSequence :: NonEscapeCharacter is the CV of the NonEscapeCharacter.
The CV of NonEscapeCharacter :: SourceCharacter but not one of EscapeCharacter or LineTerminator is the UTF-16 Encoding (clause 6) of the code point value of SourceCharacter.
The CV of HexEscapeSequence :: \ HexDigit HexDigit is the code unit value that is (16 times the MV of the first HexDigit) plus the MV of the second HexDigit.
The CV of UnicodeEscapeSequence :: \u{HexDigit HexDigit HexDigit HexDigit} is the code unit value that is (4096 times the MV of the first HexDigit) plus (256 times the MV of the second HexDigit) plus (16 times the MV of the third HexDigit) plus the MV of the fourth HexDigit.
The CV of UnicodeEscapeSequence :: \x{HexDigit} is the UTF-16 Encoding (clause 6) of the MV of HexDigits.
11.8.5 Regular Expression Literals

NOTE A regular expression literal is an input element that is converted to a RegExp object (see 21.2) each time the literal is evaluated. Two regular expression literals in a program evaluate to regular expression objects that never compare as === to each other even if the two literals' contents are identical. A RegExp object may also be created at runtime by new RegExp (see 21.2.3.2) or calling the RegExp constructor as a function (21.2.3.1).

The productions below describe the syntax for a regular expression literal and are used by the input element scanner to find the end of the regular expression literal. The source code comprising the RegularExpressionBody and the RegularExpressionFlags are subsequently parsed using the more stringent ECMAScript Regular Expression grammar (21.2.1).

An implementation may extend the ECMAScript Regular Expression grammar defined in 21.2.1, but it must not extend the RegularExpressionBody and RegularExpressionFlags productions defined below or the productions used by these productions.

Syntax

RegularExpressionLiteral ::=
    / RegularExpressionBody / RegularExpressionFlags

RegularExpressionBody ::=
    RegularExpressionFirstChar RegularExpressionChars

RegularExpressionChars ::=
    [empty] RegularExpressionChar RegularExpressionChars

RegularExpressionFirstChar ::= RegularExpressionNonTerminator but not one of * or \ or / or [ RegularExpressionBackslashSequence RegularExpressionClass

RegularExpressionChar ::= RegularExpressionNonTerminator but not one of \ or / or [ RegularExpressionBackslashSequence RegularExpressionClass

RegularExpressionBackslashSequence ::= \ RegularExpressionNonTerminator

RegularExpressionNonTerminator ::= SourceCharacter but not LineTerminator

RegularExpressionClass ::= [ RegularExpressionClassChars ]

RegularExpressionClassChars ::= [empty] RegularExpressionClassChars RegularExpressionClassChar

RegularExpressionClassChar ::= RegularExpressionNonTerminator but not one of ] or \ RegularExpressionBackslashSequence

RegularExpressionFlags ::= [empty] RegularExpressionFlags IdentifierPart

NOTE Regular expression literals may not be empty; instead of representing an empty regular expression literal, the characters // start a single-line comment. To specify an empty regular expression, use: /(/?/)/.
Static Semantics: Early Errors

RegularExpressionFlags :: RegularExpressionFlags IdentifierPart

- It is a Syntax Error if IdentifierPart contains a Unicode escape sequence.

Static Semantics: BodyText

RegularExpressionLiteral :: / RegularExpressionBody / RegularExpressionFlags

1. Return the source code that was recognised as RegularExpressionBody.

Static Semantics: FlagText

RegularExpressionLiteral :: / RegularExpressionBody / RegularExpressionFlags

2. Return the source code that was recognised as RegularExpressionFlags.

11.8.6 Template Literal Lexical Components

Syntax

Template ::
  NoSubstitutionTemplate
  TemplateHead

NoSubstitutionTemplate ::
  ` TemplateCharactersopt `

TemplateHead ::
  ` TemplateCharactersopt $ {
    TemplateSubstitutionTail ::
      TemplateMiddle
      TemplateTail
    TemplateMiddle ::
      } TemplateCharactersopt $ {
    TemplateTail ::
      } TemplateCharactersopt

TemplateCharacters ::
  SourceCharacter
  but not one of ` or \ or $)
  $ \ lookahead $ ( \\
  \ EscapeSequence
  LineContinuation

Static Semantics: TV's and TRV's

A template literal component is interpreted as a sequence of Unicode characters. The Template Value (TV) of a literal component is described in terms of code unit values (CV, 11.8.4) contributed by the various parts of the template literal component. As part of this process, some Unicode characters within the template component are interpreted as having a mathematical value (MV, 11.8.3). In determining a TV, escape sequences are replaced by the code unit of the Unicode characters represented by the escape sequence. The Template Raw Value (TRV) is similar to a Template Value with the difference that in TRVs escape sequences are interpreted literally.

Commented [AWB945]: Note that the original proposal allowed $IdentifierName to be used as a substitution without () around the name. Line terminations characters are simply handled as literal SourceCharacters. I find this troublesome. Shouldn't we have some sort of normalizations of line terminators. Otherwise, the actual characters in a multi-line template are at the mercy of the authors editor/OS.
The TV and TRV of NoSubstitutionTemplate \` ` is the empty code unit sequence.
- The TV and TRV of TemplateHead :: ` $` is the empty code unit sequence.
- The TV and TRV of TemplateMiddle :: $` $` is the empty code unit sequence.
- The TV and TRV of TemplateTail :: ` ` is the empty code unit sequence.
- The TV of NoSubstitutionTemplate :: ` TemplateCharacters ` is the TRV of TemplateCharacters.
- The TV of TemplateHead :: ` TemplateCharacters $` is the TV of TemplateCharacters.
- The TV of TemplateMiddle :: ` TemplateCharacters $` is the TV of TemplateCharacters.
- The TV of TemplateTail :: ` TemplateCharacters ` is the TV of TemplateCharacters.
- The TV of TemplateCharacters :: TemplateCharacter is the TV of TemplateCharacter.
- The TV of TemplateCharacters :: TemplateCharacter TemplateCharacters is a sequence consisting of the code units in the TV of TemplateCharacter followed by all the code units in the TV of TemplateCharacters in order.
- The TV of TemplateCharacter :: SourceCharacter but not one of ` ` or ` \ ` or ` $` is the UTF-16 Encoding (clause 6) of the code point value of SourceCharacter.
- The TV of TemplateCharacter :: $ [lookahead e | } is the code unit value 0x0024.
- The TV of TemplateCharacter :: ` \ \ \ EscapeSequence ` is the CV of EscapeSequence.
- The TV of TemplateCharacter :: LineContinuation is the TV of LineContinuation.
- The TV of TemplateCharacter :: LineContinuation ` LineTerminatorSequence ` is the empty code unit sequence.
- The TRV of NoSubstitutionTemplate :: ` TemplateCharacters ` is the TRV of TemplateCharacters.
- The TRV of TemplateHead :: ` TemplateCharacters $` is the TRV of TemplateCharacters.
- The TRV of TemplateMiddle :: ` TemplateCharacters $` is the TRV of TemplateCharacters.
- The TRV of TemplateTail :: ` TemplateCharacters ` is the TRV of TemplateCharacters.
- The TRV of TemplateCharacters :: TemplateCharacter TemplateCharacters is a sequence consisting of the code units in the TRV of TemplateCharacter followed by all the code units in the TRV of TemplateCharacters, in order.
- The TRV of TemplateCharacter :: SourceCharacter but not one of ` ` or ` \ ` or ` $` is the UTF-16 Encoding (clause 6) of the code point value of SourceCharacter.
- The TRV of TemplateCharacter :: $ [lookahead e | } is the code unit value 0x0024.
- The TRV of TemplateCharacter :: ` \ \ \ EscapeSequence ` is the sequence consisting of the code unit value 0x003C followed by the code units of TRV of EscapeSequence.
- The TRV of TemplateCharacter :: LineContinuation is the TRV of LineContinuation.
- The TRV of EscapeSequence :: CharacterEscapeSequence ` is the TRV of the CharacterEscapeSequence.
- The TRV of EscapeSequence :: ` HexEscapeSequence ` is the code unit value 0x0030.
- The TRV of EscapeSequence :: HexEscapeSequence ` in the TRV of the HexEscapeSequence.
- The TRV of EscapeSequence :: UnicodeEscapeSequence ` is the TRV of the UnicodeEscapeSequence.
- The TRV of CharacterEscapeSequence :: SingleEscapeCharacter is the TRV of the SingleEscapeCharacter.
- The TRV of CharacterEscapeSequence :: NonEscapeCharacter ` is the CV of the NonEscapeCharacter.
- The TRV of SingleEscapeCharacter ` one of ` ` \ ` ` \ \ ` ` \ \ ` ` \ \ \ ` ` \ \ \ ` is the CV of the SourceCharacter that is that Single character.
- The TRV of HexEscapeSequence :: ` HexDigit HexDigit is the sequence consisting of code unit value 0x0078 followed by TRV of the first HexDigit followed by the TRV of the second HexDigit.
- The TRV of UnicodeEscapeSequence :: ` HexDigits HexDigit is the sequence consisting of code unit value 0x0075 followed by TRV of the first HexDigit followed by the TRV of the second HexDigit.
- The TRV of UnicodeEscapeSequence :: ` HexDigits ` is the sequence consisting of code unit value 0x0075 followed by code unit value 0x007B followed by TRV of HexDigits followed by code unit value 0x007D.
- The TRV of HexDigits :: HexDigit is the TRV of HexDigit.
- The TRV of HexDigits :: HexDigits HexDigit is the sequence consisting of TRV of HexDigits followed by TRV of HexDigit.
- The TRV of a HexDigit ` is the CV of the SourceCharacter that is that HexDigit.
• The TRV of LineContinuation :: \ LineTerminatorSequence is the sequence consisting of the code unit value 0x005C followed by the code units of TRV of LineTerminatorSequence.
• The TRV of LineTerminatorSequence :: <LF> is the code unit value 0x000A.
• The TRV of LineTerminatorSequence :: <CR> [lookahead = <LF>] is the code unit value 0x000D.
• The TRV of LineTerminatorSequence :: <LS> is the code unit value 0x2028.
• The TRV of LineTerminatorSequence :: <PS> is the code unit value 0x2029.
• The TRV of LineTerminatorSequence :: <CR><LF> is the sequence consisting of the code unit value 0x000D followed by the code unit value 0x000A.

NOTE TV excludes the code units of LineContinuation while TRV includes them.

11.9 Automatic Semicolon Insertion

Certain ECMAScript statements (empty statement, let and const declarations, variable statement, expression statement, debugger statement, continue statement, break statement, return statement, and throw statement) must be terminated with semicolons. Such semicolons may always appear explicitly in the source text. For convenience, however, such semicolons may be omitted from the source text in certain situations. These situations are described by saying that semicolons are automatically inserted into the source code token stream in those situations.

11.9.1 Rules of Automatic Semicolon Insertion

There are three basic rules of semicolon insertion:

1. When, as the script is parsed from left to right, a token (called the offending token) is encountered that is not allowed by any production of the grammar, then a semicolon is automatically inserted before the offending token if one or more of the following conditions is true:
   • The offending token is separated from the previous token by at least one LineTerminator.
   • The offending token is a binary operation.

2. When, as the script is parsed from left to right, the end of the input stream of tokens is encountered and the parser is unable to parse the input token stream as a single complete ECMAScript script, then a semicolon is automatically inserted at the end of the input stream.

3. When, as the script is parsed from left to right, a token is encountered that is allowed by some production of the grammar, but the production is a restricted production and the token would be the first token for a terminal or nonterminal immediately following the annotation "[no LineTerminator here]" within the restricted production (and therefore such a token is called a restricted token), and the restricted token is separated from the previous token by at least one LineTerminator, then a semicolon is automatically inserted before the restricted token.

However, there is an additional overriding condition on the preceding rules: a semicolon is never inserted automatically if the semicolon would then be parsed as an empty statement or if that semicolon would become one of the two semicolons in the header of a for statement (see 13.6.3).

NOTE The following are the only restricted productions in the grammar:

PrefixExpression:
   LeftHandSideExpression [no LineTerminator here] ++
   LeftHandSideExpression [no LineTerminator here] --

ContinueStatement:
   continue [no LineTerminator here] Identifier ;

BreakStatement:
   break [no LineTerminator here] Identifier ;

ReturnStatement:
   return [no LineTerminator here] Expression ;
The practical effect of these restricted productions is as follows:

When a `++` or `--` token is encountered where the parser would treat it as a postfix operator, and at least one `LineTerminator` occurred between the preceding token and the `++` or `--` token, then a semicolon is automatically inserted before the `++` or `--` token.

When a `continue`, `break`, `return`, or `throw` token is encountered and a `LineTerminator` is encountered before the next token, a semicolon is automatically inserted after the `continue`, `break`, `return`, or `throw` token.

The resulting practical advice to ECMAScript programmers is:

- A postfix `++` or `--` operator should appear on the same line as its operand.
- An `Expression` in a `return` or `throw` statement should start on the same line as the `return` or `throw` token.
- An `Identifier` in a `break` or `continue` statement should be on the same line as the `break` or `continue` token.

### 11.9.2 Examples of Automatic Semicolon Insertion

The source
```
{ 1 2 } 3
```

is not a valid sentence in the ECMAScript grammar, even with the automatic semicolon insertion rules. In contrast, the source
```
{ 1 2 } 3
```

is also not a valid ECMAScript sentence, but is transformed by automatic semicolon insertion into the following:
```
{ 1 ;2 ;} 3;
```

which is a valid ECMAScript sentence.

The source
```
for (a; b)
```

is not a valid ECMAScript sentence and is not altered by automatic semicolon insertion because the semicolon is needed for the header of a `for` statement. Automatic semicolon insertion never inserts one of the two semicolons in the header of a `for` statement.

The source
```
return a + b
```

is transformed by automatic semicolon insertion into the following:
```
return;
a + b;
```

NOTE The expression `a + b` is not treated as a value to be returned by the `return` statement, because a `LineTerminator` separates it from the token `return`.

The source
```
a = b +c
```

is transformed by automatic semicolon insertion into the following:
a = b;
++c;

NOTE  The token ++ is not treated as a postfix operator applying to the variable b, because a LineTerminator occurs between b and ++.

The source

```javascript
if (a > b)
    else c = d
```

is not a valid ECMAScript sentence and is not altered by automatic semicolon insertion before the else token, even though no production of the grammar applies at that point, because an automatically inserted semicolon would then be parsed as an empty statement.

The source

```javascript
a = b + c
(d + e).print()
```

is not transformed by automatic semicolon insertion, because the parenthesised expression that begins the second line can be interpreted as an argument list for a function call:

```javascript
a = b + c(d + e).print()
```

In the circumstance that an assignment statement must begin with a left parenthesis, it is a good idea for the programmer to provide an explicit semicolon at the end of the preceding statement rather than to rely on automatic semicolon insertion.

### 12 ECMAScript Language: Expressions

#### 12.1 Primary Expressions

**Syntax**

```
PrimaryExpression : this
    Identifier
    Literal
    ArrayInitialiser
    ObjectLiteral
    FunctionExpression
    ClassExpression
    GeneratorExpression
    GeneratorComprehension
    RegularExpressionLiteral
    TemplateLiteral
    CoverParenthesisedExpressionAndArrowParameterList

CoverParenthesisedExpressionAndArrowParameterList : 
    { Expression }
    { Identifier }
    { Expression , . . . , Identifier }
```

**Supplemental Syntax**

When processing the production PrimaryExpression : CoverParenthesisedExpressionAndArrowParameterList the following grammar is used to refine the interpretation of CoverParenthesisedExpressionAndArrowParameterList.

```
ParenthesisedExpression : 
    { Expression }
```

**Static Semantics**

© Ecma International 2013
Static Semantics: CoveredParenthesisedExpression

CoverParenthesisedExpressionAndArrowParameterList: ( Expression )

1. Return the result of parsing the lexical token stream matched by CoverParenthesisedExpressionAndArrowParameterList using ParenthesisedExpression as the goal symbol.

Static Semantics: IsValidSimpleAssignmentTarget

PrimaryExpression:
this
Literal
ArrayInitialiser
ObjectInitialiser
FunctionExpression
ClassExpression
GeneratorExpression
GeneratorComprehension
RegularExpressionLiteral
TemplateLiteral

1. Return false.

PrimaryExpression: Identifier

1. If this PrimaryExpression is contained in strict code and StringValue of Identifier is "eval" or "arguments", then return false.
2. Return true.

PrimaryExpression: CoverParenthesisedExpressionAndArrowParameterList

1. Let expr be CoverParenthesisedExpression of CoverParenthesisedExpressionAndArrowParameterList.
2. Return IsValidSimpleAssignmentTarget of expr.

12.1.1 The this Keyword

Runtime Semantics: Evaluation

PrimaryExpression: this

1. Return the result of calling the ThisResolution abstract operation.

12.1.2 Identifier Reference

Runtime Semantics: Evaluation

PrimaryExpression: Identifier

1. Let ref be the result of performing Identifier Resolution as specified in 8.3.1 using the IdentifierName corresponding to Identifier.
2. Return ref.

NOTE: The result of evaluating an Identifier is always a value of type Reference.
12.1.3 Literals

Syntax

Literal:
- NullLiteral
- ValueLiteral

ValueLiteral:
- BooleanLiteral
- NumericLiteral
- StringLiteral

Runtime Semantics

Runtime Semantics: Evaluation

Literal: NullLiteral
1. Return null.

ValueLiteral: BooleanLiteral
1. Return false if BooleanLiteral is the token BooleanLiteral :: false
2. Return true if BooleanLiteral is the token BooleanLiteral :: true

ValueLiteral: NumericLiteral
1. Return the number whose value is MV of NumericLiteral as defined in 11.8.3.

ValueLiteral: StringLiteral
1. Return the string whose elements are the SV of StringLiteral as defined in 11.8.4.

12.1.4 Array Initialiser

Syntax

ArrayInitialiser:
- ArrayLiteral
- ArrayComprehension

12.1.4.1 Array Literal

NOTE
An ArrayLiteral is an expression describing the initialisation of an Array object, using a list, of zero or more expressions each of which represents an array element, enclosed in square brackets. The elements need not be literals; they are evaluated each time the array initialiser is evaluated.

Array elements may be elided at the beginning, middle or end of the element list. Whenever a comma in the element list is not preceded by an AssignmentExpression (i.e., a comma at the beginning or after another comma), the missing array element contributes to the length of the Array and increases the index of subsequent elements. Elided array elements are not defined. If an element is elided at the end of an array, that element does not contribute to the length of the Array.

Syntax

ArrayLiteral:
- [ Elisionopt ]
- [ ElementList ]
- [ ElementList , Elisionopt ]
ElementList :  
  Elisionopt AssignmentExpression  
  Elisionopt SpreadElement  
  ElementList , Elisionopt AssignmentExpression  
  ElementList , Elisionopt SpreadElement

Elision :  
  ,  
SpreadElement :  
  ... AssignmentExpression

Static Semantics

Static Semantics: Elision Width

Elision :  
1. Return the numeric value 1.

Elision : Elision ,  
1. Let preceding be the Elision Width of Elision.  
2. Return preceding + 1.

Runtime Semantics

Runtime Semantics: Array Accumulation

With parameters array and nextIndex.

ElementList : Elisionopt AssignmentExpression

1. Let padding be the Elision Width of Elision; if Elision is not present, use the numeric value zero.  
2. Let initResult be the result of evaluating AssignmentExpression.  
3. Let initValue be GetValue(initResult).  
4. ReturnIfAbrupt(initValue).  
5. Let created be the result of calling the [[DefineOwnProperty]] internal method of array with arguments ToString(nextIndex + padding) and the Property Descriptor { [[Value]]: initValue, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true }.  
6. Assert: created is true.  
7. Return nextIndex + padding + 1.

ElementList : Elisionopt SpreadElement

1. Let padding be the Elision Width of Elision; if Elision is not present, use the numeric value zero.  
2. Return the result of performing Array Accumulation for SpreadElement with arguments array and nextIndex + padding.

ElementList : ElementList , Elisionopt AssignmentExpression

1. Let postIndex be the result of performing Array Accumulation for ElementList with arguments array and nextIndex.  
2. ReturnIfAbrupt(postIndex).  
3. Let padding be the Elision Width of Elision; if Elision is not present, use the numeric value zero.  
4. Let initResult be the result of evaluating AssignmentExpression.  
5. Let initValue be GetValue(initResult).  
6. ReturnIfAbrupt(initValue).
7. Let \( \text{created} \) be the result of calling the \([\text{DefineOwnProperty}]\) internal method of \( \text{array} \) with arguments
\( \text{ToString(ToUint32(postIndex+padding))} \) and the Property Descriptor \( \{ [\text{Value}]: \text{initValue}, [\text{Writable}]: \text{true}, [\text{Enumerable}]: \text{true}, [\text{Configurable}]: \text{true} \} \).
8. Assert: \( \text{created} \) is \text{true}.
9. Return \( \text{postIndex}+\text{padding}+1 \).

ElementList : ElementList , Elisionopt , SpreadElement
1. Let \( \text{postIndex} \) be the result of performing Array Accumulation for \( \text{ElementList} \) with arguments \( \text{array} \) and \( \text{nextIndex} \).
2. ReturnIfAbrupt(\( \text{postIndex} \)).
3. Let \( \text{padding} \) be the Elision Width of \( \text{Elision} \); if \( \text{Elision} \) is not present, use the numeric value zero.
4. Return the result of performing Array Accumulation for \( \text{SpreadElement} \) with arguments \( \text{array} \) and \( \text{postIndex}+\text{padding} \).

SpreadElement : . . . AssignmentExpression
1. Let \( \text{spreadRef} \) be the result of evaluating AssignmentExpression.
2. Let \( \text{spreadValue} \) be GetValue(\( \text{spreadRef} \)).
3. Let \( \text{spreadObj} \) be ToObject(\( \text{spreadValue} \)).
4. ReturnIfAbrupt(\( \text{spreadObj} \)).
5. Let \( \text{lenVal} \) be the result of calling Get(\( \text{spreadObj} \), "length").
6. Let \( \text{spreadLen} \) be ToUint32(\( \text{lenVal} \)).
7. ReturnIfAbrupt(\( \text{spreadLen} \)).
8. Let \( \text{n}=0 \);
9. Repeat, while \( \text{n} < \text{spreadLen} \)
   a. Let \( \text{exists} \) be the result of HasProperty(\( \text{spreadObj} \), \( \text{ToString(\( \text{n} \))} \))
   b. ReturnIfAbrupt(\( \text{exists} \)).
   c. If \( \text{exists} \) is \text{true} then,
      i. Let \( \text{v} \) be the result of calling the [[Get]] internal method of \( \text{spreadObj} \) passing \( \text{ToString(\( \text{n} \))} \) as the argument.
      ii. ReturnIfAbrupt(\( \text{v} \)).
      iii. Let \( \text{created} \) be the result of calling the \([\text{DefineOwnProperty}]\) internal method of \( \text{array} \) with arguments
          \( \text{ToString(ToUint32(\text{nextIndex}))} \) and Property Descriptor \( \{ [\text{Value}]: \text{v}, [\text{Writable}]: \text{true}, [\text{Enumerable}]: \text{true}, [\text{Configurable}]: \text{true} \} \).
      iv. Assert: \( \text{created} \) is \text{true}.
   d. Let \( \text{n} = \text{n}+1 \).
   e. Let \( \text{nextIndex} = \text{nextIndex}+1 \).
10. Return \( \text{nextIndex} \).

NOTE [\text{DefineOwnProperty}] \ is used to ensure that own properties are defined for the array even if the standard built-in \text{Array} prototype object has been modified in a manner that would preclude the creation of new own properties using [[Set]].

Runtime Semantics: Evaluation

ArrayLiteral : [ Elisionopt ]
1. Let \( \text{array} \) be the result of the abstract operation ArrayCreate with argument \( \text{0} \).
2. Let \( \text{pad} \) be the Elision Width of \( \text{Elision} \); if \( \text{Elision} \) is not present, use the numeric value zero.
3. Call Put(\( \text{array} \), "length", \( \text{pad}, \text{false} \)).
4. Return \( \text{array} \).

ArrayLiteral : [ ElementList ]
1. Let \( \text{array} \) be the result of the abstract operation ArrayCreate with argument \( \text{0} \).
2. Let \( \text{len} \) be the result of performing Array Accumulation for \( \text{ElementList} \) with arguments \( \text{array} \) and \( \text{0} \).
3. ReturnIfAbrupt(\( \text{len} \)).
4. Call Put(\( \text{array} \), "length", \( \text{len}, \text{false} \)).
5. Return \( \text{array} \).
ArrayLiteral: [ ElementList, Elision? ]

1. Let array be the result of the abstract operation ArrayCreate with argument 0.
2. Let len be the result of performing Array Accumulation for ElementList with arguments array and 0.
3. ReturnIfAbrupt(len).
4. Let padding be the Elision Width of Elision; if Elision is not present, use the numeric value zero.
5. Call Put(array, "length", ToUint32(padding+len), false).
6. Return array.

12.1.4.2 Array Comprehension

Syntax

ArrayComprehension:
  [ Comprehension ]

Comprehension:
    ComprehensionFor ComprehensionQualifierTail

ComprehensionQualifierTail:
  AssignmentExpression
  ComprehensionQualifier ComprehensionQualifierTail

ComprehensionQualifier:
  ComprehensionFor
  ComprehensionIf

ComprehensionFor:
  for ( ForBinding of AssignmentExpression )

ComprehensionIf:
  if ( AssignmentExpression )

ForBinding:
  BindingIdentifier
  BindingPattern

Static Semantics

Static Semantics: Early Errors

ComprehensionFor: for ( ForBinding of AssignmentExpression )

- It is a Syntax Error if the BoundNames of ForBinding contains any duplicate entries.

Runtime Semantics

Runtime Semantics: Binding Initialisation

With arguments value and environment.

NOTE undefined is passed for environment to indicate that a PutValue operation should be used to assign the initialisation value. This is the case for var statements formal parameter lists of non-strict functions. In those cases a lexical binding is hosted and preinitialised prior to evaluation of its initialiser.

ForBinding: BindingPattern

1. Let obj be ToObject(value).
2. ReturnIfAbrupt(obj).
3. Return the result of performing Binding Initialisation for BindingPattern passing obj and environment as the arguments.

**Runtime Semantics: ComprehensionEvaluation**

With argument accumulator.

NOTE undefined is passed for accumulator to indicate that a comprehension component is being evaluated as part of a generator comprehension. Otherwise, the value of accumulator is the array object into the elements of an array comprehension are to be accumulated.

**Comprehension:** ComprehensionFor ComprehensionQualifierTail

1. Return the result of performing QualifierEvaluation for ComprehensionFor with arguments ComprehensionQualifierTail and accumulator.

**ComprehensionQualifierTail:** ComprehensionQualifier ComprehensionQualifierTail

1. Return the result of performing QualifierEvaluation for ComprehensionQualifier with arguments ComprehensionQualifierTail and accumulator.

**ComprehensionQualifierTail:** AssignmentExpression

1. Let valueRef be the result of evaluating AssignmentExpression.
2. Let value be GetValue(valueRef).
3. ReturnIfAbrupt(value).
4. If accumulator is not undefined, then
   a. Assert: this is part of an array comprehension.
   b. Assert: accumulator is an exotic array object so access to its length property should never fail.
   c. Let len be the result of Get(accumulator, "length").
   d. If len ≥ 2^31 - 1, then throw a RangeError exception.
   e. Let putStatus be the result of Put(accumulator, ToString(len), value, true).
   f. ReturnIfAbrupt(putStatus).
   g. Increase len by 1.
   h. Let putStatus be the result of Put(accumulator, "length", len, true).
   i. ReturnIfAbrupt(putStatus).
   j. Return NormalCompletion(undefined).
5. Assert: accumulator is undefined, so this is part of a generator comprehension.
6. Let yieldStatus be the result of GeneratorYield(CreateIterResultObject(value, false)).
7. ReturnIfAbrupt(yieldStatus).
8. Return NormalCompletion(undefined).

**Runtime Semantics: QualifierEvaluation**

With arguments tail and accumulator.

NOTE undefined is passed for accumulator to indicate that a comprehension component is being evaluated as part of a generator comprehension. Otherwise, the value of accumulator is the array object into the elements of an array comprehension are to be accumulated.

**ComprehensionFor:** for (ForBinding of AssignmentExpression)

1. Let expRef be the result of evaluating AssignmentExpression.
2. Let expValue be GetValue(expRef).
3. Let obj be ToObject(expValue).
4. ReturnIfAbrupt(obj).
5. Let iterator be the result of performing Invoke with arguments obj, @ @ iterator, and an empty List.
6. Let keys be ToObject(iterator).
7. ReturnIfAbrupt(keys).
8. Let `oldEnv` be the running execution context’s LexicalEnvironment.
9. Repeat
   a. Let `nextResult` be the result of `IteratorNext(keys)`.
   b. ReturnIfAbrupt(`nextResult`).
   c. Let `done` be `IteratorComplete(`nextResult`).
   d. ReturnIfAbrupt(`done`).
   e. If `done` is `true`, then return `true`.
   f. Let `nextValue` be `IteratorValue(`nextResult`).
   g. ReturnIfAbrupt(`nextValue`).
   h. Let `forEnv` be the result of calling `NewDeclarativeEnvironment` passing `oldEnv` as the argument.
   i. For each element `name` of the `BoundNames` of `ForBinding`
      i. Call `forEnv`’s `CreateMutableBinding` concrete method with argument `name`.
      ii. Assert: The above call to `CreateMutableBinding` will never an return an abrupt completion.
   j. Let `status` be the result of performing Binding Initialisation for `ForBinding` passing `nextValue` and `forEnv` as the arguments.
   k. ReturnIfAbrupt(`status`).
   l. Set the running execution context’s LexicalEnvironment to `forEnv`.
   m. Let `continue` be the result of performing ComprehensionEvaluation for `tail` with argument `accumulator`.
   n. Set the running execution context’s LexicalEnvironment to `oldEnv`.
   o. ReturnIfAbrupt(`continue`).

ComprehensionIf : `if` (AssignmentExpression )
1. Let `valueRef` be the result of evaluating `AssignmentExpression`.
2. Let `value` be `GetValue(`valueRef`).
3. Let `boolValue` be `ToBoolean(`value`).
4. ReturnIfAbrupt(`boolValue`).
5. If `boolValue` is `true`, then
   a. Return the result of performing ComprehensionEvaluation for `tail` with argument `accumulator`.
6. Else,
   a. Return NormalCompletion( `undefined`).

Runtime Semantics: Evaluation

ArrayComprehension : [ Comprehension ]
1. Let `array` be the result of the abstract operation `ArrayCreate` with argument `0`.
2. Let `status` be the result of performing ComprehensionEvaluation for `Comprehension` with argument `array`.
3. ReturnIfAbrupt(`status`).
4. Return `array`.

12.1.5 Object Initialiser

NOTE 1 An object initialiser is an expression describing the initialisation of an Object, written in a form resembling a literal. It is a list of zero or more pairs of property names and associated values, enclosed in curly braces. The values need not be literals; they are evaluated each time the object initialiser is evaluated.

Syntax

ObjectLiteral : 
  { } 
  { PropertyDefinitionList } 
  { PropertyDefinitionList , } 

PropertyDefinitionList : 
  PropertyDefinition 
  PropertyDefinitionList , PropertyDefinition
PropertyDefinition : IdentifierName
  CoverInitialisedName
  PropertyName : AssignmentExpression
  MethodDefinition

PropertyName : LiteralPropertyName
  ComputedPropertyName

LiteralPropertyName : IdentifierName
  StringLiteral
  NumericLiteral

ComputedPropertyName : [
  AssignmentExpression
]

CoverInitialisedName :
  IdentifierName
  Initialiser

Initialiser :
  = AssignmentExpression

NOTE 2  MethodDefinition is defined in 14.3.

NOTE 3  In certain contexts, ObjectLiteral is used as a cover grammar for a more restricted secondary grammar. The CoverInitialisedName production is necessary to fully cover these secondary grammars. However, use of this production results in an early Syntax Error in normal contexts where an actual ObjectLiteral is expected.

Static Semantics

Static Semantics: Early Errors

In addition to describing an actual object initialiser the ObjectLiteral productions are also used as a cover grammar for ObjectAssignmentPattern (12.13.3). When ObjectLiteral appears in a context where ObjectAssignmentPattern is required, the following Early Error rules are not applied.

ObjectLiteral : { PropertyDefinitionList }
and
ObjectLiteral : { PropertyDefinitionList , }

- It is a Syntax Error if PropertyNameList of PropertyDefinitionList contains any duplicate entries, unless one of the following conditions are true for each duplicate entry:
  1. The source code corresponding to PropertyDefinitionList is not strict code and all occurrences in the list of the duplicated entry were obtained from productions of the form PropertyDefinition : PropertyName : AssignmentExpression.
  2. The duplicated entry occurs exactly twice in the list and one occurrence was obtained from a get accessor MethodDefinition and the other occurrence was obtained from a set accessor MethodDefinition.

PropertyDefinition : MethodDefinition

- It is a Syntax Error if ReferencesSuper of MethodDefinition is true.

PropertyDefinition : IdentifierName

- It is a Syntax Error if IdentifierName is a ReservedWord.

Commented [AW8849]: The currently prevailing position in TC39 is that use of super should not be allowed in object literals. This restriction is arbitrary in the sense that the runtime semantics would work.
PropertyDefinition : CoverInitialisedName

- Always throw a Syntax Error if this production is present

NOTE This production exists so that ObjectLiteral can serve as a cover grammar for ObjectAssignmentPattern (12.13.3). It cannot occur in an actual object initialiser.

Static Semantics: Contains

With parameter symbol.

PropertyDefinition : MethodDefinition

1. If symbol is MethodDefinition, return true.
2. Return false.

NOTE Static semantic rules that depend upon substructure generally do not look into function definitions.

LiteralPropertyName : IdentifierName

1. If symbol is a ReservedWord, return false.
2. If symbol is an Identifier and StringValue of symbol is the same value as the StringValue of IdentifierName, return true;
3. Return false.

Static Semantics: IsComputedPropertyName

PropertyName : LiteralPropertyName

1. Return false.

PropertyName : ComputedPropertyName

1. Return true.

Static Semantics: IsValidSimpleAssignmentTarget

PrimaryExpression : Literal

1. Return false.

Static Semantics: PropName

PropertyDefinition : IdentifierName

1. Return String Value of IdentifierName.

PropertyDefinition : PropertyName : AssignmentExpression

1. Return PropName of PropertyName.

LiteralPropertyName : StringLiteral

1. Return a String value whose characters are the SV of the StringLiteral.

LiteralPropertyName : NumericLiteral

1. Let nbr be the result of forming the value of the NumericLiteral.
2. Return ToString(nbr).
ComputedPropertyName : [ AssignmentExpression ]

1. Return empty.

Static Semantics: PropertyNameList

PropertyDefinitionList : PropertyDefinition

1. If PropName of PropertyDefinition is empty, return a new empty List.
2. Return a new List containing PropName of PropertyDefinition.

PropertyDefinitionList : PropertyDefinitionList , PropertyDefinition

1. Let list be PropertyNameList of PropertyDefinitionList.
2. If PropName of PropertyDefinition is empty, return list.
3. Append PropName of PropertyDefinition to the end of list.
4. Return list.

Runtime Semantics

Runtime Semantics: Evaluation

ObjectLiteral : { }

1. Return the result of the abstract operation ObjectCreate with the intrinsic object %ObjectPrototype% as its argument.

ObjectLiteral : { PropertyDefinitionList } { PropertyDefinitionList , }

1. Let obj be the result of the abstract operation ObjectCreate with the intrinsic object %ObjectPrototype% as its argument.
2. Let status be the result of performing PropertyDefinition Evaluation of PropertyDefinitionList with argument obj.
3. ReturnIfAbrupt(status).
4. Return obj.

PropertyDefinition : IdentifierName

1. Return StringValue of IdentifierName.

PropertyDefinition : PropertyName : AssignmentExpression

1. Return the result of evaluating PropertyName.

LiteralPropertyName : IdentifierName

1. Return StringValue of IdentifierName.

LiteralPropertyName : StringLiteral

1. Return a String value whose characters are the SV of the StringLiteral.

LiteralPropertyName : NumericLiteral

1. Let nbr be the result of forming the value of the NumericLiteral.
2. Return ToString(nbr).
ComputedPropertyName : [ AssignmentExpression ]

1. Let exprValue be the result of evaluating AssignmentExpression.
2. Let propName be GetValue(exprValue).
3. ReturnIfAbrupt(propName).
4. Return ToPropertyKey(propName).

Runtime Semantics: Property Definition Evaluation

With parameter object and optional parameter functionPrototype.

PropertyDefinitionList : PropertyDefinitionList , PropertyDefinition

1. Let status be the result of performing Property Definition Evaluation of PropertyDefinitionList with argument object.
2. ReturnIfAbrupt(status).
3. Return the result of performing Property Definition Evaluation of PropertyDefinition with argument object.

PropertyDefinition : IdentifierName

1. Let propName be StringValue of IdentifierName.
2. Let exprValue be the result of performing Identifier Resolution as specified in 8.3.1 using IdentifierName.
3. Let propValue be GetValue(exprValue).
4. ReturnIfAbrupt(propValue).
5. Let desc be the Property Descriptor([Value]: propValue, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true)
6. Return the result of DefinePropertyOrThrow(object, propName, desc).

NOTE An alternative semantics for this production is given in B.3.1.

12.1.6 Function Defining Expressions

See 14.1 for PrimaryExpression : FunctionExpression.

See 14.4 for PrimaryExpression : GeneratorExpression.

See 14.5 for PrimaryExpression : ClassExpression.
12.1.7 Generator Comprehensions

Syntax

GeneratorComprehension :  
(  Comprehension  )

12.1.7.1 Static Semantics

Static Semantics: Early Errors

GeneratorComprehension :  (  Comprehension  )

• It is a Syntax Error if Comprehension Contains YieldExpression is true.

12.1.7.2 Runtime Semantics

Runtime Semantics: Evaluation

GeneratorComprehension :  (  Comprehension  )

1. If GeneratorComprehension is contained in strict mode code, then let strict be true; otherwise let strict be false.
2. Let scope be the LexicalEnvironment of the running execution context.
3. Let parameters be the production: FormalParameters : [empty].
4. Using Comprehension from the production that is being evaluated, let body be the supplemental syntactic grammar production: GeneratorBody : Comprehension.
5. Let closure be the result of performing the GeneratorFunctionCreate abstract operation with arguments Arrow, parameters, body, scope, and strict.
6. Let prototype be the result of the abstract operation ObjectCreate with the intrinsic object %GeneratorPrototype% as its argument.
7. Perform the abstract operation MakeConstructor with arguments closure, true, and prototype.
8. Let iterator be the result of calling the [[Call]] internal method of closure with undefined as thisArgument and a empty List as argumentsList.
9. Return iterator.

NOTE The GeneratorFunction object created in step 5 is not observable from ECMAScript code so an implementation may choose to avoid its allocation and initialization. In that case other semantically equivalent means must be used to allocate and initialise the iterator object in step 8. In either case, the prototype object created in step 6 must be created because it is potentially observable as the value of the iterator object’s [[Prototype]] internal data property.

12.1.8 Regular Expression Literals

Syntax

See 11.8.4.

Static Semantics

Static Semantics: Early Errors

PrimaryExpression :  RegularExpressionLiteral

• It is a Syntax Error if BodyText of RegularExpressionLiteral cannot be recognised using the goal symbol Pattern of the ECMAScript RegExp grammar specified in 21.2.1.
• It is a Syntax Error if FlagText of RegularExpressionLiteral contains any character other than “g”, “i”, “m”, “u”, or “y”, or if it contains the same character more than once.

Runtime Semantics
Runtime Semantics: Evaluation

PrimaryExpression : RegularExpressionLiteral

1. A regular expression literal evaluates to a value of the Object type that is an instance of the standard built-in constructor RegExp. This value is determined in two steps: first, the characters comprising the regular expression's RegularExpressionBody and RegularExpressionFlags production expansions are collected uninterpreted into two Strings Pattern and Flags, respectively. Then each time the literal is evaluated, a new object is created as if by the expression `new RegExp(Pattern, Flags)` where RegExp is the standard built-in constructor with that name. The newly constructed object becomes the value of the RegularExpressionLiteral.

12.1.9 Template Literals

Syntax

TemplateLiteral : NoSubstitutionTemplate

TemplateSpan : TemplateTail

TemplateMiddleList : TemplateMiddle Expression

Static Semantics

Static Semantics: TemplateStrings

With parameter raw.

TemplateLiteral : NoSubstitutionTemplate

1. If raw is false, then
   a. Let string be the TV of NoSubstitutionTemplate.
2. Else,
   a. Let string be the TRV of NoSubstitutionTemplate.
3. Return a List containing the single element, string.

TemplateLiteral : TemplateHead Expression [Lexical goalInputElementTail] TemplateSpans

1. If raw is false, then
   a. Let head be the TV of TemplateHead.
2. Else,
   a. Let head be the TRV of TemplateHead.
3. Let tail be TemplateStrings of TemplateSpans with argument raw.
4. Return a List containing head followed by the element, in order of tail.

TemplateSpan : TemplateTail

1. If raw is false, then
   a. Let tail be the TV of TemplateTail.
2. Else,
   a. Let tail be the TRV of TemplateTail.
3. Return a List containing the single element, tail.

TemplateSpans : TemplateMiddleList [Lexical goalInputElementTail] TemplateTail

Commented [AWB851]: Should convert to a multistep algorithm and breakout a static semantic rule for the early error.
1. Let middle be TemplateStrings of TemplateMiddleList with argument raw.
2. If raw is false, then
   a. Let tail be the TV of TemplateTail.
3. Else,
   a. Let tail be the TRV of TemplateTail.
4. Return a List containing the elements, in order, of middle followed by tail.

TemplateMiddleList : TemplateMiddle Expression
1. If raw is false, then
   a. Let string be the TV of TemplateMiddle.
2. Else,
   a. Let string be the TRV of TemplateMiddle.
3. Return a List containing the single element, string.

TemplateMiddleList : TemplateMiddleList [LiteralInputElementTemplateTail] TemplateMiddle Expression
1. Let front be TemplateStrings of TemplateMiddleList with argument raw.
2. If raw is false, then
   a. Let last be the TV of TemplateMiddle.
3. Else,
   a. Let last be the TRV of TemplateMiddle.
4. Append last as the last element of the List front.
5. Return front.

Runtime Semantics
Runtime Semantics: ArgumentListEvaluation
TemplateLiteral : NoSubstitutionTemplate
1. Let siteObj be the result of the abstract operation GetTemplateCallSite passing this TemplateLiteral production as the argument.
2. Return a List containing the one element which is siteObj.
TemplateLiteral : TemplateHead Expression [LiteralInputElementTemplateTail] TemplateSpans
1. Let siteObj be the result of the abstract operation GetTemplateCallSite passing this TemplateLiteral production as the argument.
2. Let firstSub be the result of evaluating Expression.
3. ReturnIfAbrupt(firstSub).
4. Let restSub be SubstitutionEvaluation of TemplateSpans.
5. ReturnIfAbrupt(restSub).
6. Assert, restSub is a List.
7. Return a List whose first element is siteObj, whose second elements is firstSub, and whose subsequent elements are the elements of restSub, in order. restSub may contain no elements.

Runtime Semantics: GetTemplateCallSite Abstract Operation
The abstract operation GetTemplateCallSite is called with a grammar production, templateLiteral, as an argument. It performs the following steps:
1. If a call site object for the source code corresponding to templateLiteral has already been created by a previous call to this abstract operation, then
   a. Return that call site object.
2. Let cookedStrings be TemplateStrings of templateLiteral with argument false.
3. Let rawStrings be TemplateStrings of templateLiteral with argument true.
4. Let count be the number of elements in the List cookedStrings.
5. Let siteObj be the result of the abstract operation ArrayCreate with argument count.
6. Let rawObj be the result of the abstract operation ArrayCreate with argument count.
7. Let \(index\) be 0.
8. Repeat while \(index < count\):
   a. Let \(prop\) be ToString(index).
   b. Let \(cookedValue\) be the string value at 0-based position \(index\) of the List \(cookedStrings\).
   c. Call the \([[\text{DefineOwnProperty}]]\) internal method of \(siteObj\) with arguments \(prop\) and Property Descriptor \([[\text{Value}]\): \(cookedValue\), [[\text{Enumerable}]]: true, [[\text{Writable}]]: false, [[\text{Configurable}]]: false].
   d. Let \(rawValue\) be the string value at 0-based position \(index\) of the List \(rawStrings\).
   e. Call the \([[\text{DefineOwnProperty}]]\) internal method of \(siteObj\) with arguments \(prop\) and Property Descriptor \([[\text{Value}]\): \(rawValue\), [[\text{Enumerable}]]: true, [[\text{Writable}]]: false, [[\text{Configurable}]]: false].
   f. Let \(index\) be \(index\) + 1.
9. Perform SetIntegrityLevel(rawObj, "frozen").
10. Perform SetIntegrityLevel(siteObj, "frozen").
11. Remember an association between the source code corresponding to templateLiteral and \(siteObj\) such that \(siteObj\) can be retrieved in subsequent calls to this abstract operation.
12. Return \(siteObj\).

**NOTE 1** The creation of a call site object cannot result in an abrupt completion.

**NOTE 2** Each templateLiteral in the program code is associated with a unique template call site object that is used in the evaluation of tagged templates (12.2.6.1). The same call site object is used each time a specific tagged template is evaluated. Whether call site objects are created lazily upon first evaluation of the templateLiteral or eagerly prior to first evaluation is an implementation choice that is not observable to ECMAScript code.

**Runtime Semantics: SubstitutionEvaluation**

**TemplateSpans : TemplateTail**

1. Return an empty List.

**TemplateSpans : TemplateMiddleList [lexical goal \(InputElement\) TemplateTail]**

1. Return the result of SubstitutionEvaluation of TemplateMiddleList.

**TemplateMiddleList : TemplateMiddleExpression**

1. Let \(sub\) be the result of evaluating Expression.
2. ReturnIfAbrupt(sub).
3. Return a List containing only \(sub\).

**TemplateMiddleList : TemplateMiddleList [lexical goal \(InputElement\) TemplateTail]**

1. Let \(preceeding\) be the result of SubstitutionEvaluation of TemplateMiddleList.
2. ReturnIfAbrupt(preceeding).
3. Let \(next\) be the result of evaluating Expression.
4. ReturnIfAbrupt(next).
5. Append \(next\) as the last element of the List preceeding.
6. Return preceeding.

**Runtime Semantics: Evaluation**

**TemplateLiteral : NoSubstitutionTemplate**

1. Return the string value whose elements are the TV of NoSubstitutionTemplate as defined in 11.8.6.

**TemplateLiteral : TemplateHead Expression [lexical goal \(InputElement\) TemplateTail]**

1. Let \(head\) be the TV of TemplateHead as defined in 11.8.6.
2. Let \( sub \) be the result of evaluating \( \text{Expression} \).
3. Let \( middle \) be \( \text{ToString}(sub) \).
4. ReturnIfAbrupt(middle).
5. Let \( tail \) be the result of evaluating \( \text{TemplateSpans} \).
6. ReturnIfAbrupt(tail).
7. Return the string value whose elements are the code units of \( head \) followed by the code units of \( tail \).

TemplateSpans : TemplateTail

1. Let \( tail \) be the TV of \( \text{TemplateTail} \) as defined in 11.8.6.
2. Return the string whose elements are the code units of \( tail \).

TemplateSpans : TemplateMiddleList \{ Lexical goal TemplateTail \} TemplateTail

1. Let \( head \) be the result of evaluating TemplateMiddleList.
2. ReturnIfAbrupt(head).
3. Let \( tail \) be the TV of \( \text{TemplateTail} \) as defined in 11.8.6.
4. Return the string whose elements are the elements of \( head \) followed by the elements of \( tail \).

TemplateMiddleList : TemplateMiddleExpression

1. Let \( head \) be the TV of \( \text{TemplateMiddle} \) as defined in 11.8.6.
2. Let \( sub \) be the result of evaluating \( \text{Expression} \).
3. Let \( middle \) be \( \text{ToString}(sub) \).
4. ReturnIfAbrupt(middle).
5. Return the sequence of characters consisting of the code units of \( head \) followed by the elements of \( middle \).

TemplateMiddleList : TemplateMiddleList \{ Lexical goal TemplateTail \} TemplateMiddleExpression

1. Let \( rest \) be the result of evaluating TemplateMiddleList.
2. ReturnIfAbrupt(rest).
3. Let \( middle \) be the TV of \( \text{TemplateMiddle} \) as defined in 11.8.6.
4. Let \( sub \) be the result of evaluating \( \text{Expression} \).
5. Let \( last \) be \( \text{ToString}(sub) \).
6. ReturnIfAbrupt(last).
7. Return the sequence of characters consisting of the elements of \( rest \) followed by the code units of \( middle \) followed by the elements of \( last \).

12.1.10 The Grouping Operator

Static Semantics: Early Errors

PrimaryExpression : CoverParenthesisedExpressionAndArrowParameterList

- It is a Syntax Error if the lexical token sequence matched by CoverParenthesisedExpressionAndArrowParameterList cannot be parsed with no tokens left over using ParenthesisedExpression as the goal symbol.
- All Early Errors rules for ParenthesisedExpression and its derived productions also apply to the CoverParenthesisedExpression of CoverParenthesisedExpressionAndArrowParameterList.

Static Semantics: IsValidSimpleAssignmentTarget

PrimaryExpression : CoverParenthesisedExpressionAndArrowParameterList
1. Let \( expr \) be CoverParenthesisedExpression of CoverParenthesisedExpressionAndArrowParameterList.
2. Return IsValidSimpleAssignmentTarget of \( expr \).

ParenthesisedExpression : ( Expression )
1. Return IsValidSimpleAssignmentTarget of Expression.

Runtime Semantics: Evaluation

PrimaryExpression : CoverParenthesisedExpressionAndArrowParameterList

1. Let expr be CoverParenthesisedExpression of CoverParenthesisedExpressionAndArrowParameterList.
2. Return the result of evaluating expr.

ParenthesisedExpression : ( Expression )

1. Return the result of evaluating Expression. This may be of type Reference.

NOTE This algorithm does not apply GetValue to the result of evaluating Expression. The principal motivation for this is so that operators such as delete and typeof may be applied to parenthesised expressions.

12.2 Left-Hand-Side Expressions

Syntax

MemberExpression : [ Lexical goal inputElementRegExp ] PrimaryExpression
    MemberExpression [ Expression ]
    MemberExpression . IdentifierName
    MemberExpression TemplateLiteral
    super [ Expression ]
    super . IdentifierName
    new super Argumentsopt
    new MemberExpression Arguments

NewExpression : MemberExpression
    new NewExpression

CallExpression : MemberExpression Arguments
    super Arguments
    CallExpression Arguments
    CallExpression [ Expression ]
    CallExpression . IdentifierName
    CallExpression TemplateLiteral

Arguments : ()
    ( ArgumentList )

ArgumentList : AssignmentExpression
    . . . AssignmentExpression
    ArgumentList , AssignmentExpression
    ArgumentList , . . . AssignmentExpression

LeftHandSideExpression : NewExpression
    CallExpression

Static Semantics: Contains
With parameter `symbol`,

MemberExpression : MemberExpression . IdentifierName

1. If `MemberExpression` Contains `symbol` is `true`, return `true`.
2. If `symbol` is a `ReservedWord`, return `false`.
3. If `symbol` is an `Identifier` and `StringValue` of `symbol` is the same value as the `StringValue` of `IdentifierName`, return `true`.
4. Return `false`.

MemberExpression : `super` . IdentifierName

1. If `symbol` is the `ReservedWord` `super`, return `true`.
2. If `symbol` is a `ReservedWord`, return `false`.
3. If `symbol` is an `Identifier` and `StringValue` of `symbol` is the same value as the `StringValue` of `IdentifierName`, return `true`.
4. Return `false`.

CallExpression : CallExpression . IdentifierName

1. If `CallExpression` Contains `symbol` is `true`, return `true`.
2. If `symbol` is a `ReservedWord`, return `false`.
3. If `symbol` is an `Identifier` and `StringValue` of `symbol` is the same value as the `StringValue` of `IdentifierName`, return `true`.
4. Return `false`.

MemberExpression : `new` `super`

1. If `symbol` is the `ReservedWord` `super`, return `true`.
2. If `symbol` is the `ReservedWord` `new`, return `true`.
3. Return `false`.

MemberExpression : `new` `super` Arguments

1. If `symbol` is the `ReservedWord` `super`, return `true`.
2. If `symbol` is the `ReservedWord` `new`, return `true`.
3. Return the result of `Arguments` Contains `symbol`.

Static Semantics: IsValidSimpleAssignmentTarget

CallExpression :

- CallExpression [ Expression ]
- CallExpression . IdentifierName

MemberExpression :

- MemberExpression [ Expression ]
- MemberExpression . IdentifierName
  super [ Expression ]
  super . IdentifierName

1. Return `true`.

CallExpression :

- MemberExpression Arguments
  super Arguments
  CallExpression Arguments
  CallExpression TemplateLiteral

Commented [AWB1055]: These are false, because we disallow host functions returning reference values.
NewExpression : `new` NewExpression

MemberExpression :
  `new super` Arguments;
  `new` MemberExpression Arguments

1. Return false.

12.2.1 Property Accessors

Properties are accessed by name, using either the dot notation:

```
MemberExpression . IdentifierName
CallExpression . IdentifierName
```

or the bracket notation:

```
MemberExpression [ Expression ]
CallExpression [ Expression ]
```

The dot notation is explained by the following syntactic conversion:

```
MemberExpression . IdentifierName
```

is identical in its behaviour to

```
MemberExpression [ <identifier-name-string> ]
```

and similarly

```
CallExpression . IdentifierName
```

is identical in its behaviour to

```
CallExpression [ <identifier-name-string> ]
```

where `<identifier-name-string>` is a string literal containing the same sequence of characters after processing of Unicode escape sequences as the `IdentifierName`.

Runtime Semantics: Evaluation

```
MemberExpression : MemberExpression [ Expression ]
```

1. Let `baseReference` be the result of evaluating `MemberExpression`.
2. Let `baseValue` be `GetValue(baseReference)`.
3. ReturnIfAbrupt(`baseValue`).
4. Let `propertyNameReference` be the result of evaluating `Expression`.
5. Let `propertyNameValue` be `GetValue(propertyNameReference)`.
6. ReturnIfAbrupt(`propertyNameValue`).
7. Let `bv` be `CheckObjectCoercible(baseValue)`.
8. ReturnIfAbrupt(`bv`).
9. Let `propertyNameString` be `ToString(propertyNameValue)`.
10. If the code matched by the syntactic production that is being evaluated is strict mode code, let `strict` be `true`, else let `strict` be `false`.
11. Return a value of type `Reference` whose base value is `bv` and whose referenced name is `propertyNameString`, and whose strict reference flag is `strict`.

```
CallExpression : CallExpression [ Expression ]
```

Is evaluated in exactly the same manner as `MemberExpression : MemberExpression [ Expression ]` except that the contained `CallExpression` is evaluated in step 1.
12.2.2 The new Operator

Runtime Semantics: Evaluation

NewExpression : new NewExpression
1. Let ref be the result of evaluating NewExpression.
2. Let constructor be GetValue(ref).
3. ReturnIfAbrupt(constructor).
4. If IsConstructor(constructor) is false, throw a TypeError exception.
5. Return the result of calling the [[Construct]] internal method on constructor with an empty List as the argument.

MemberExpression : new MemberExpression Arguments
1. Let ref be the result of evaluating MemberExpression.
2. Let constructor be GetValue(ref).
3. ReturnIfAbrupt(constructor).
4. Let argList be the result of evaluating Arguments, producing an internal List of argument values (12.2.5).
5. ReturnIfAbrupt(argList).
6. If IsConstructor(constructor) is false, throw a TypeError exception.
7. Return the result of calling the [[Construct]] internal method on constructor, passing argList as the argument.

12.2.3 Function Calls

Runtime Semantics: Evaluation

CallExpression : MemberExpression Arguments
1. Let ref be the result of evaluating MemberExpression.
2. If this CallExpression is in a tail position (14.6) then let tailCall be true, otherwise let tailCall be false.
3. Return the result of the abstract operation EvaluateCall with arguments ref, Arguments, and tailCall.

CallExpression : CallExpression Arguments
1. Let ref be the result of evaluating CallExpression.
2. If this CallExpression is in a tail position (14.6) then let tailCall be true, otherwise let tailCall be false.
3. Return the result of the abstract operation EvaluateCall with arguments ref, Arguments, and tailCall.

Runtime Semantics: EvaluateCall Abstract Operation

The abstract operation EvaluateCall takes as arguments a value ref, and a syntactic grammar production arguments, and a Boolean argument tailPosition. It performs the following steps:

1. If Type(ref) is Reference, then
   a. If IsPropertyReference(ref) is true, then
      i. Return the result of the abstract operation EvaluateMethodCall with arguments ref, arguments, and tailPosition.
   b. Else, the base of ref is an Environment Record
      i. Let thisValue be the result of calling the WithBaseObject concrete method of GetBase(ref).
      ii. If thisValue is not undefined, then
          1. Let newRef be a value of type Reference whose base value is thisValue and whose referenced name is GetReferencedName(ref), and whose strict reference flag is IsStrictReference(ref).
          2. Return the result of the abstract operation EvaluateMethodCall with arguments newRef, arguments, and tailPosition.
   2. Else Type(ref) is not Reference:
      a. Let thisValue be undefined.

Commented [AWB8956]: TODO probably need to do something about new operators in tail position.

Commented [AWB757]: TODO: tail calls.
Jan 19 meeting notes: Tentative decision is to support tail calls in strict mode only.

Commented [AWB1558]: Explicit property references are handled as method calls.

Commented [AWB1559]: Implicit property references (via a with binding or global object binding) are also handled as method calls.
3. Assert: This is a direct function call rather than a method call.
4. Let func be GetValue(ref).
5. ReturnIfAbrupt(func).
7. ReturnIfAbrupt(argList).
8. If Type(func) is not Object, throw a TypeError exception.
9. If IsCallable(func) is false, throw a TypeError exception.
10. If tailPosition is true, then perform the PrepareForTailCall abstract operation.
11. Let result be the result of calling the [[Call]] internal method on func, passing thisValue as the thisArgument and argList as the argumentsList.
12. Assert: If tailPosition is true, the above call will not return here, but instead evaluation will continue with the resumption of leafCallerContext as the running execution context.
13. Assert: If result is not an abrupt completion then Type(result) is an ECMAScript language type
14. Return result.

Runtime Semantics: EvaluateMethodCall Abstract Operation

The abstract operation EvaluateMethodCall takes as arguments a value ref, and a syntactic grammar production arguments, and a Boolean argument tailPosition. It performs the following steps:

1. Assert: Type(ref) is Reference and IsPropertyReference(ref) is true
2. Let base be the result of calling GetBase(ref).
3. If HasPrimitiveBase(ref) is true, then
   a. Assert: In this case, base will never be null or undefined
   b. Let base be ToObject(base)
4. Let argList be the result of performing ArgumentListEvaluation of arguments.
5. ReturnIfAbrupt(argList).
6. Let key be GetReferencedName(ref).
7. If tailPosition is true, then perform the PrepareForTailCall abstract operation.
8. Let result be the result of calling the [[Invoke]] internal method on base, passing key, argList, and thisValue
9. Assert: If tailPosition is true, the above [[Invoke]] will not return here, but instead evaluation will continue with the resumption of leafCallerContext as the running execution context.
10. Assert: If result is not an abrupt completion then Type(result) is an ECMAScript language type
11. Return result.

12.2.4 The super Keyword

Static Semantics

MemberExpression : super [ Expression ]
super : IdentifierName
new super Arguments

CallExpression : super Arguments

• It is a Syntax Error if the source code parsed with this production is global code that is not eval code.
• It is a Syntax Error if the source code parsed with this production is eval code and the source code is not being processed by a direct call to eval that is contained in function code.

Runtime Semantics: Evaluation

MemberExpression : super [ Expression ]
1. Let propertyNameReference be the result of evaluating Expression.
2. Let propertyNameValue be GetValue(propertyNameReference).
3. Let `propertyKey` be `ToPropertyKey(propertyNameValue)`.  
4. If the code matched by the syntactic production that is being evaluated is strict mode code, let `strict` be `true`, else let `strict` be `false`.  
5. Return the result of `MakeSuperReference(propertyKey, strict)`.

**MemberExpression : super . IdentifierName**

1. Let `propertyKey` be `StringValue of IdentifierName`.  
2. If the code matched by the syntactic production that is being evaluated is strict mode code, let `strict` be `true`, else let `strict` be `false`.  
3. Return the result of `MakeSuperReference(propertyKey, strict)`.

**MemberExpression : new super Arguments**

1. If the code matched by the syntactic production that is being evaluated is strict mode code, let `strict` be `true`, else let `strict` be `false`.  
2. Let `ref` be the result of `MakeSuperReference(undefined, strict)`.  
3. Let `constructor` be `GetValue(ref)`.  
4. ReturnIfAbrupt(`constructor`).  
5. If `Arguments` is present, then  
   a. Let `argList` be the result of evaluating `Arguments`, producing an internal List of argument values (12.2.5).  
   b. ReturnIfAbrupt(`argList`).  
5. Else,  
   a. Let `argList` be a new empty List.  
7. If `IsConstructor(constructor)` is `false`, throw a `TypeError` exception.  
8. Return the result of calling the `[[Construct]]` internal method on `constructor`, passing `argList` as the argument.

**CallExpression : super Arguments**

1. If the code matched by the syntactic production that is being evaluated is strict mode code, let `strict` be `true`, else let `strict` be `false`.  
2. Let `ref` be the result of `MakeSuperReference(undefined, strict)`.  
3. ReturnIfAbrupt(`ref`).  
4. If this `CallExpression` is in a tail position (13.7) then let `tailCall` be `true`, otherwise let `tailCall` be `false`.  
5. Return the result of the abstract operation `EvaluateMethodCall` with arguments `ref`, `Arguments`, and `tailCall`.

**Runtime Semantics: Abstract Operation MakeSuperReference(propertyKey, strict)**

1. Let `env` be the result of performing the `GetThisEnvironment` abstract operation.  
2. If the result of calling the `HasSuperBinding` concrete method of `env` is `false`, then throw a `ReferenceError` exception.  
3. Let `actualThis` be the result of calling the `GetThisBinding` concrete method of `env`.  
4. Let `baseValue` be the result of calling the `GetSuperBase` concrete method of `env`.  
5. Let `bv` be `CheckObjectCoercible(baseValue)`.  
6. ReturnIfAbrupt(`bv`).  
7. If `propertyKey` is `undefined`, then  
   a. Let `propertyKey` be the result of calling the `GetMethodName` concrete method of `env`.  
8. Return a value of type `Reference` that is a Super Reference whose base value is `bv`, whose referenced name is `propertyKey`, whose thisValue is `actualThis`, and whose strict reference flag is `strict`.

**12.2.5 Argument Lists**

The evaluation of an argument list produces a List of values (see 6.2.2).
12.2.5.1 Runtime Semantics

ArgumentListEvaluation

Arguments: {}  
1. Return an empty List.

ArgumentList : AssignmentExpression

1. Let ref be the result of evaluating AssignmentExpression.
2. Let arg be GetValue(ref).
3. ReturnIfAbrupt(arg).
4. Return a List whose sole item is arg.

ArgumentList : ... AssignmentExpression

1. Let list be an empty List.
2. Let spreadRef be the result of evaluating AssignmentExpression.
3. Let spreadValue be GetValue(spreadRef).
4. Let spreadObj be ToObject(spreadValue).
5. ReturnIfAbrupt(spreadObj).
6. Let lenVal be the result of calling Get(spreadObj, "length").
7. Let spreadLen be ToUint32(lenVal).
8. ReturnIfAbrupt(spreadLen).
9. Let n = 0.
10. Repeat, while n < spreadLen
   a. Let nextArg be the result of calling Get(spreadObj, ToString(n)).
   b. ReturnIfAbrupt(nextArg).
   c. Append nextArg as the last element of list.
   d. Let n = n+1.
11. Return list.

ArgumentList : ArgumentList , AssignmentExpression

1. Let precedingArgs be the result of evaluating ArgumentList.
2. ReturnIfAbrupt(precedingArgs).
3. Let ref be the result of evaluating AssignmentExpression.
4. Let arg be GetValue(ref).
5. ReturnIfAbrupt(arg).
6. Return a List whose length is one greater than the length of precedingArgs and whose items are the items of precedingArgs, in order, followed at the end by arg which is the last item of the new list.

ArgumentList : ArgumentList , ... AssignmentExpression

1. Let precedingArgs be an empty List.
2. Let spreadRef be the result of evaluating AssignmentExpression.
3. Let spreadValue be GetValue(spreadRef).
4. Let spreadObj be ToObject(spreadValue).
5. ReturnIfAbrupt(spreadObj).
6. Let lenVal be the result of calling Get(spreadObj, "length").
7. Let spreadLen be ToUint32(lenVal).
8. ReturnIfAbrupt(spreadLen).
9. Let n = 0.
10. Repeat, while n < spreadLen
   a. Let nextArg be the result of calling Get(spreadObj, ToString(n)).
   b. ReturnIfAbrupt(nextArg).
   c. Append nextArg as the last element of precedingArgs.
   d. Let n = n+1.

12.2.6 Tagged Templates

12.2.6.1 Runtime Semantics

Runtime Semantics: Evaluation

`MemberExpression : MemberExpression TemplateLiteral`

1. Let `tagRef` be the result of evaluating `MemberExpression`.
2. If this `MemberExpression` is in a tail position (13.7) then let `tailCall` be `true`, otherwise let `tailCall` be `false`.
3. Return the result of the abstract operation `EvaluateCall` with arguments `tagRef`, `TemplateLiteral`, and `tailCall`.

`CallExpression : CallExpression TemplateLiteral`

1. Let `tagRef` be the result of evaluating `CallExpression`.
2. If this `CallExpression` is in a tail position (13.7) then let `tailCall` be `true`, otherwise let `tailCall` be `false`.
3. Return the result of the abstract operation `EvaluateCall` with arguments `tagRef`, `TemplateLiteral`, and `tailCall`.

12.3 Postfix Expressions

Syntax

`PostfixExpression : LeftHandSideExpression [no LineTerminator here] ++`

`PostfixExpression : LeftHandSideExpression [no LineTerminator here] --`

Static Semantics

Static Semantics: Early Errors

`PostfixExpression : LeftHandSideExpression [no LineTerminator here] ++`

`PostfixExpression : LeftHandSideExpression [no LineTerminator here] --`

- It is an early Reference Error if `IsValidSimpleAssignmentTarget` of `LeftHandSideExpression` is `false`.

Static Semantics: IsValidSimpleAssignmentTarget

`PostfixExpression : LeftHandSideExpression [no LineTerminator here] ++`

`PostfixExpression : LeftHandSideExpression [no LineTerminator here] --`

1. Return `false`.

12.3.1 Postfix Increment Operator

Runtime Semantics: Evaluation

`PostfixExpression : LeftHandSideExpression [no LineTerminator here] ++`

1. Let `lhs` be the result of evaluating `LeftHandSideExpression`.
2. Let `oldValue` be `ToNumber(GetValue(lhs))`.
3. ReturnIfAbrupt(oldValue).
4. Let newValue be the result of adding the value 1 to oldValue, using the same rules as for the + operator (see 12.6.3).
5. Let status be PutValue(lhs, newValue).
6. ReturnIfAbrupt(status).
7. Return oldValue.

12.3.2 Postfix Decrement Operator

Runtime Semantics: Evaluation

1. Let lhs be the result of evaluating LeftHandSideExpression.
2. Let oldValue be ToNumber(GetValue(lhs)).
3. Let newValue be the result of subtracting the value 1 from oldValue, using the same rules as for the – operator (12.6.3).
4. Let status be PutValue(lhs, newValue).
5. ReturnIfAbrupt(status).
6. Return oldValue.

12.4 Unary Operators

Syntax

UnaryExpression :
  PostfixExpression
  delete UnaryExpression
  void UnaryExpression
  typeof UnaryExpression
  ++ UnaryExpression
  -- UnaryExpression
  + UnaryExpression
  – UnaryExpression
  ~ UnaryExpression
  ! UnaryExpression

Static Semantics

Static Semantics: Early Errors

UnaryExpression :
  ++ UnaryExpression
  -- UnaryExpression

• It is an early Reference Error if IsValidSimpleAssignmentTarget of UnaryExpression is false.

Static Semantics: IsValidSimpleAssignmentTarget

UnaryExpression :
  delete UnaryExpression
  void UnaryExpression
  typeof UnaryExpression
  ++ UnaryExpression
  – UnaryExpression
  ~ UnaryExpression
  ! UnaryExpression
1. Return false.

12.4.1 The delete Operator

Static Semantics: Early Errors

UnaryExpression: delete UnaryExpression

- It is a Syntax Error if the UnaryExpression is contained in strict code and the derived UnaryExpression is PrimaryExpression: Identifier.
- It is a Syntax Error if the derived UnaryExpression is PrimaryExpression: CoverParenthesizedExpressionAndArrowParameterList and derives a production that, if used in place of UnaryExpression, would produce a Syntax Error according to these rules. This rule is recursively applied.

NOTE The last rule means that expressions such as delete (((foo))) produce early errors because of recursive application of the first rule.

Runtime Semantics: Evaluation

UnaryExpression: delete UnaryExpression

1. Let ref be the result of evaluating UnaryExpression.
2. ReturnIfAbrupt(ref).
3. If Type(ref) is not Reference, return true.
4. If IsUnresolvableReference(ref) is true, then,
   a. If IsStrictReference(ref) is true, then throw a SyntaxError exception.
   b. Return true.
5. If IsPropertyReference(ref) is true, then
   a. If IsSuperReference(ref), then throw a ReferenceError exception.
   b. Let deleteStatus be the result of calling the [[Delete]] internal method on ToObject(GetBase(ref)), providing GetReferencedName(ref) as the argument.
   c. ReturnIfAbrupt(deleteStatus).
   d. If deleteStatus is false and IsStrictReference(ref) is true, then throw a TypeError exception.
   e. Return deleteStatus.
6. Else ref is a Reference to an Environment Record binding,
   a. Let bindings be GetBase(ref).
   b. Return the result of calling the DeleteBinding concrete method of bindings, providing GetReferencedName(ref) as the argument.

NOTE When a delete operator occurs within strict mode code, a SyntaxError exception is thrown if its UnaryExpression is a direct reference to a variable, function argument, or function name. In addition, if a delete operator occurs within strict mode code and the property to be deleted has the attribute ( [[Configurable]]: false ), a TypeError exception is thrown.

12.4.2 The void Operator

Runtime Semantics: Evaluation

UnaryExpression: void UnaryExpression

1. Let expr be the result of evaluating UnaryExpression.
2. Let status be GetValue(expr).
3. ReturnIfAbrupt(status).
4. Return undefined.

NOTE GetValue must be called even though its value is not used because it may have observable side-effects.
12.4.3 The typeof Operator

Runtime Semantics: Evaluation

UnaryExpression : typeof UnaryExpression

1. Let val be the result of evaluating UnaryExpression.
2. If Type(val) is Reference, then
   a. If IsUnresolvableReference(val) is true, return “undefined”.
   b. Let val be GetValue(val).
3. ReturnIfAbrupt(val).
4. Return a String determined by Type(val) according to Table 31.

Table 31 — typeof Operator Results

<table>
<thead>
<tr>
<th>Type of val</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>“undefined”</td>
</tr>
<tr>
<td>Null</td>
<td>“object”</td>
</tr>
<tr>
<td>Boolean</td>
<td>“boolean”</td>
</tr>
<tr>
<td>Number</td>
<td>“number”</td>
</tr>
<tr>
<td>String</td>
<td>“string”</td>
</tr>
<tr>
<td>Object (ordinary and does not implement [[Call]])</td>
<td>“object”</td>
</tr>
<tr>
<td>Object (is a Symbol exotic object)</td>
<td>“symbol”</td>
</tr>
<tr>
<td>Object (standard exotic other than Symbol and does not implement [[Call]])</td>
<td>“object”</td>
</tr>
<tr>
<td>Object (implements [[Call]])</td>
<td>“function”</td>
</tr>
<tr>
<td>Object (non-standard exotic and does not implement [[Call]])</td>
<td>Implementation-defined. May not be “undefined”, “boolean”, “number”, “symbol”, or “string”.</td>
</tr>
</tbody>
</table>

NOTE: Implementations are discouraged from defining new typeof result values for non-standard exotic objects. If possible “object” should be used for such objects.

12.4.4 Prefix Increment Operator

Runtime Semantics: Evaluation

UnaryExpression += UnaryExpression

1. Let expr be the result of evaluating UnaryExpression.
2. Let oldValue be ToNumber(GetValue(expr)).
3. ReturnIfAbrupt(oldValue).
4. Let newValue be the result of adding the value 1 to oldValue, using the same rules as for the + operator (see 12.6.3).
5. Let status be PutValue(expr, newValue).
6. ReturnIfAbrupt(status).
7. Return newValue.
12.4.5 Prefix Decrement Operator

Runtime Semantics: Evaluation

\[ UnaryExpression : -- UnaryExpression \]

1. Let \( expr \) be the result of evaluating \( UnaryExpression \).
2. Let \( oldValue \) be ToNumber(GetValue(\( expr \))).
3. ReturnIfAbrupt(\( oldValue \)).
4. Let \( newValue \) be the result of subtracting the value 1 from \( oldValue \), using the same rules as for the \( - \) operator (see 12.6.3).
5. Let \( status \) be PutValue(\( expr \), \( newValue \)).
6. ReturnIfAbrupt(\( status \)).
7. Return \( newValue \).

12.4.6 Unary + Operator

NOTE The unary + operator converts its operand to Number type.

Runtime Semantics: Evaluation

\[ UnaryExpression : + UnaryExpression \]

1. Let \( expr \) be the result of evaluating \( UnaryExpression \).
2. Return ToNumber(GetValue(\( expr \))).

12.4.7 Unary − Operator

NOTE The unary − operator converts its operand to Number type and then negates it. Negating +0 produces −0, and negating −0 produces +0.

Runtime Semantics: Evaluation

\[ UnaryExpression : − UnaryExpression \]

1. Let \( expr \) be the result of evaluating \( UnaryExpression \).
2. Let \( oldValue \) be ToNumber(GetValue(\( expr \))).
3. ReturnIfAbrupt(\( oldValue \)).
4. If \( oldValue \) is NaN, return NaN.
5. Return the result of negating \( oldValue \); that is, compute a Number with the same magnitude but opposite sign.

12.4.8 Bitwise NOT Operator ( ~ )

Runtime Semantics: Evaluation

\[ UnaryExpression : ~ UnaryExpression \]

1. Let \( expr \) be the result of evaluating \( UnaryExpression \).
2. Let \( oldValue \) be ToInt32(GetValue(\( expr \))).
3. ReturnIfAbrupt(\( oldValue \)).
4. Return the result of applying bitwise complement to \( oldValue \). The result is a signed 32-bit integer.

12.4.9 Logical NOT Operator ( ! )

Runtime Semantics: Evaluation

\[ UnaryExpression : ! UnaryExpression \]
1. Let `expr` be the result of evaluating `UnaryExpression`.
2. Let `oldValue` be `ToBoolean(GetValue(expr))`.
3. ReturnIfAbrupt(`oldValue`).
4. If `oldValue` is `true`, return `false`.
5. Return `true`.

### 12.5 Multiplicative Operators

**Syntax**

```
MultiplicativeExpression ::=
    UnaryExpression
    MultiplicativeExpression * UnaryExpression
    MultiplicativeExpression / UnaryExpression
    MultiplicativeExpression % UnaryExpression
```

**Static Semantics:** `IsValidSimpleAssignmentTarget` MultiplicativeExpression:

```
MultiplicativeExpression ::=
    MultiplicativeExpression * UnaryExpression
    MultiplicativeExpression / UnaryExpression
    MultiplicativeExpression % UnaryExpression
```

1. Return `false`.

**Runtime Semantics:** `Evaluation`

The production `MultiplicativeExpression : MultiplicativeExpression @ UnaryExpression`, where `@` stands for one of the operators in the above definitions, is evaluated as follows:

1. Let `left` be the result of evaluating `MultiplicativeExpression`.
2. Let `leftValue` be `GetValue(left)`.
3. ReturnIfAbrupt(`leftValue`).
4. Let `right` be the result of evaluating `UnaryExpression`.
5. Let `rightValue` be `GetValue(right)`.
6. Let `lNum` be `ToNumber(leftValue)`.
7. ReturnIfAbrupt(`lNum`).
8. Let `rNum` be `ToNumber(rightValue)`.
9. ReturnIfAbrupt(`rNum`).
10. Return the result of applying the specified operation (`*`, `/`, or `%`) to `lNum` and `rNum`. See the Notes below 12.5.1, 12.5.2, 12.5.3.

### 12.5.1 Applying the `*` Operator

The `*` operator performs multiplication, producing the product of its operands. Multiplication is commutative. Multiplication is not always associative in ECMAScript, because of finite precision.

The result of a floating-point multiplication is governed by the rules of IEEE 754 binary double-precision arithmetic:

- If either operand is `NaN`, the result is `NaN`.
- The sign of the result is positive if both operands have the same sign, negative if the operands have different signs.
- Multiplication of an infinity by a zero results in `NaN`.
- Multiplication of an infinity by an infinity results in an infinity. The sign is determined by the rule already stated above.
- Multiplication of an infinity by a finite nonzero value results in a signed infinity. The sign is determined by the rule already stated above.
In the remaining cases, where neither an infinity or NaN is involved, the product is computed and rounded to the nearest representable value using IEEE 754 round-to-nearest mode. If the magnitude is too large to represent, the result is then an infinity of appropriate sign. If the magnitude is too small to represent, the result is then a zero of appropriate sign. The ECMAScript language requires support of gradual underflow as defined by IEEE 754.

12.5.2 Applying the / Operator

The / operator performs division, producing the quotient of its operands. The left operand is the dividend and the right operand is the divisor. ECMAScript does not perform integer division. The operands and result of all division operations are double-precision floating-point numbers. The result of division is determined by the specification of IEEE 754 arithmetic:

- If either operand is NaN, the result is NaN.
- The sign of the result is positive if both operands have the same sign, negative if the operands have different signs.
- Division of an infinity by an infinity results in NaN.
- Division of an infinity by a zero results in an infinity. The sign is determined by the rule already stated above.
- Division of an infinity by a nonzero finite value results in a signed infinity. The sign is determined by the rule already stated above.
- Division of a finite value by an infinity results in zero. The sign is determined by the rule already stated above.
- Division of a zero by a zero results in NaN; division of zero by any other finite value results in zero, with the sign determined by the rule already stated above.
- Division of a nonzero finite value by a zero results in a signed infinity. The sign is determined by the rule already stated above.
- In the remaining cases, where neither an infinity, nor a zero, nor NaN is involved, the quotient is computed and rounded to the nearest representable value using IEEE 754 round-to-nearest mode. If the magnitude is too large to represent, the operation overflows; the result is then an infinity of appropriate sign. If the magnitude is too small to represent, the operation underflows and the result is a zero of the appropriate sign. The ECMAScript language requires support of gradual underflow as defined by IEEE 754.

12.5.3 Applying the % Operator

The % operator yields the remainder of its operands from an implied division; the left operand is the dividend and the right operand is the divisor.

NOTE In C and C++, the remainder operator accepts only integral operands; in ECMAScript, it also accepts floating-point operands.

The result of a floating-point remainder operation as computed by the % operator is not the same as the “remainder” operation defined by IEEE 754. The IEEE 754 “remainder” operation computes the remainder from a rounding division, not a truncating division, and so its behaviour is not analogous to that of the usual integer remainder operator. Instead the ECMAScript language defines % on floating-point operations to behave in a manner analogous to that of the Java integer remainder operator; this may be compared with the C library function fmod.

The result of an ECMAScript floating-point remainder operation is determined by the rules of IEEE arithmetic:

- If either operand is NaN, the result is NaN.
- The sign of the result equals the sign of the dividend.
- If the dividend is an infinity, or the divisor is a zero, or both, the result is NaN.
- If the dividend is finite and the divisor is an infinity, the result equals the dividend.
- If the dividend is a zero and the divisor is nonzero and finite, the result is the same as the dividend.
- In the remaining cases, where neither an infinity, nor a zero, nor NaN is involved, the floating-point remainder r from a dividend n and a divisor d is defined by the mathematical
relation \( r = n - (d \times q) \) where \( q \) is an integer that is negative only if \( n/d \) is negative and positive only if \( n/d \) is positive, and whose magnitude is as large as possible without exceeding the magnitude of the true mathematical quotient of \( n \) and \( d \). \( r \) is computed and rounded to the nearest representable value using IEEE 754 round-to-nearest mode.

### 12.6 Additive Operators

#### Syntax

AdditiveExpression : 

- MultiplicativeExpression + MultiplicativeExpression
- MultiplicativeExpression - MultiplicativeExpression

#### Static Semantics: `IsvalidSimpleAssignmentTarget`

AdditiveExpression :

- AdditiveExpression + MultiplicativeExpression
- AdditiveExpression - MultiplicativeExpression

1. Return `false`.

#### 12.6.1 The Addition operator ( + )

**NOTE** The addition operator either performs string concatenation or numeric addition.

#### Runtime Semantics: Evaluation

AdditiveExpression : AdditiveExpression + MultiplicativeExpression

1. Let `lref` be the result of evaluating `AdditiveExpression`.
2. Let `lval` be `GetValue(lref)`.
3. ReturnIfAbrupt(lval).
4. Let `rref` be the result of evaluating `MultiplicativeExpression`.
5. Let `rval` be `GetValue(rref)`.
6. ReturnIfAbrupt(rval).
7. Let `lprim` be `ToPrimitive(lval)`.
8. ReturnIfAbrupt(lprim).
9. Let `rprim` be `ToPrimitive(rval)`.
10. ReturnIfAbrupt(rprim).
11. If `Type(lprim)` is `String` or `Type(rprim)` is `String`, then
   a. Return the String that is the result of concatenating `ToString(lprim)` followed by `ToString(rprim)`.
12. Return the result of applying the addition operation to `ToNumber(lprim)` and `ToNumber(rprim)`. See the Note below 12.6.3.

**NOTE 1** No hint is provided in the calls to `ToPrimitive` in steps 7 and 9. All standard ECMAScript objects except `Date` objects handle the absence of a hint as if the hint `Number` were given. `Date` objects handle the absence of a hint as if the hint `String` were given. Exotic objects may handle the absence of a hint in some other manner.

**NOTE 2** Step 11 differs from step 5 of the Abstract Relational Comparison algorithm (7.2.8), by using the logical-or operation instead of the logical-and operation.

#### 12.6.2 The Subtraction Operator ( - )

#### Runtime Semantics: Evaluation

AdditiveExpression : AdditiveExpression - MultiplicativeExpression

1. Let `lref` be the result of evaluating `AdditiveExpression`.
2. Let `lval` be `GetValue(lref)`.
3. ReturnIfAbrupt(lval).
4. Let rref be the result of evaluating MultiplicativeExpression.
5. Let rval be GetValue(rref).
6. ReturnIfAbrupt(rval).
7. Let lnum be ToNumber(lval).
8. ReturnIfAbrupt(lnum).
9. Let rnum be ToNumber(rval).
10. ReturnIfAbrupt(rnum).
11. Return the result of applying the subtraction operation to lnum and rnum. See the note below 12.6.3.

12.6.3 Applying the Additive Operators to Numbers

The + operator performs addition when applied to two operands of numeric type, producing the sum of the operands. The – operator performs subtraction, producing the difference of two numeric operands.

Addition is a commutative operation, but not always associative.

The result of an addition is determined using the rules of IEEE 754 binary double-precision arithmetic:

- If either operand is NaN, the result is NaN.
- The sum of two infinities of opposite sign is NaN.
- The sum of two infinities of the same sign is the infinity of that sign.
- The sum of an infinity and a finite value is equal to the infinite operand.
- The sum of two negative zeroes is –0. The sum of two positive zeroes, or of two zeroes of opposite sign, is +0.
- The sum of a zero and a nonzero finite value is equal to the nonzero operand.
- The sum of two nonzero finite values of the same magnitude and opposite sign is +0.
- In the remaining cases, where neither an infinity, nor a zero, nor NaN is involved, and the operands have the same sign or have different magnitudes, the sum is computed and rounded to the nearest representable value using IEEE 754 round-to-nearest mode. If the magnitude is too large to represent, the operation overflows and the result is then an infinity of appropriate sign. The ECMAScript language requires support of gradual underflow as defined by IEEE 754.

NOTE The – operator performs subtraction when applied to two operands of numeric type, producing the difference of its operands; the left operand is the minuend and the right operand is the subtrahend. Given numeric operands a and b, it is always the case that a – b produces the same result as a + (–b).

12.7 Bitwise Shift Operators

Syntax

ShiftExpression :
  AdditiveExpression
  ShiftExpression << AdditiveExpression
  ShiftExpression >> AdditiveExpression
  ShiftExpression >>> AdditiveExpression

Static Semantics: IsValidSimpleAssignmentTarget

ShiftExpression :
  ShiftExpression << AdditiveExpression
  ShiftExpression >> AdditiveExpression
  ShiftExpression >>> AdditiveExpression

1. Return false.
12.7.1 The Left Shift Operator (<<)

**NOTE**  Performs a bitwise left shift operation on the left operand by the amount specified by the right operand.

**Runtime Semantics: Evaluation**

**ShiftExpression : ShiftExpression << AdditiveExpression**

1. Let lref be the result of evaluating ShiftExpression.
2. Let lval be GetValue(lref).
3. ReturnIfAbrupt(lval).
4. Let rref be the result of evaluating AdditiveExpression.
5. Let rval be GetValue(rref).
6. ReturnIfAbrupt(rval).
7. Let lnun be ToInt32(lval).
8. ReturnIfAbrupt(lnun).
9. Let rnum be ToUint32(rval).
10. ReturnIfAbrupt(rnum).
11. Let shiftCount be the result of masking out all but the least significant 5 bits of rnum, that is, compute rnum & 0x1F.
12. Return the result of left shifting lnun by shiftCount bits. The result is a signed 32-bit integer.

12.7.2 The Signed Right Shift Operator (>>) 

**NOTE**  Performs a sign-filling bitwise right shift operation on the left operand by the amount specified by the right operand.

**Runtime Semantics: Evaluation**

**ShiftExpression : ShiftExpression >> AdditiveExpression**

1. Let lref be the result of evaluating ShiftExpression.
2. Let lval be GetValue(lref).
3. ReturnIfAbrupt(lval).
4. Let rref be the result of evaluating AdditiveExpression.
5. Let rval be GetValue(rref).
6. ReturnIfAbrupt(rval).
7. Let lnun be ToInt32(lval).
8. ReturnIfAbrupt(lnun).
9. Let rnum be ToUint32(rval).
10. ReturnIfAbrupt(rnum).
11. Let shiftCount be the result of masking out all but the least significant 5 bits of rnum, that is, compute rnum & 0x1F.
12. Return the result of performing a sign-extending right shift of lnun by shiftCount bits. The most significant bit is propagated. The result is a signed 32-bit integer.

12.7.3 The Unsigned Right Shift Operator (>>>)

**NOTE**  Performs a zero-filling bitwise right shift operation on the left operand by the amount specified by the right operand.

**Runtime Semantics: Evaluation**

**ShiftExpression : ShiftExpression >>> AdditiveExpression**

1. Let lref be the result of evaluating ShiftExpression.
2. Let lval be GetValue(lref).
3. ReturnIfAbrupt(lval).
4. Let rref be the result of evaluating AdditiveExpression.
5. Let `rval` be `GetValue(rref)`.  
6. `ReturnIfAbrupt(rval)`.  
7. Let `lnum` be `ToUint32(rval)`.  
8. `ReturnIfAbrupt(lnum)`.  
9. Let `rnum` be `ToUint32(rval)`.  
10. `ReturnIfAbrupt(rnum)`.  
11. Let `shiftCount` be the result of masking out all but the least significant 5 bits of `rnum`, that is, compute `rnum & 0x1F`.  
12. Return the result of performing a zero-filling right shift of `lnum` by `shiftCount` bits. Vacated bits are filled with zero. The result is an unsigned 32-bit integer.

12.8 Relational Operators

The result of evaluating a relational operator is always of type Boolean, reflecting whether the relationship named by the operator holds between its two operands.

Syntax

```
RelationalExpression :  
  ShiftExpression  
    RelationalExpression < ShiftExpression  
    RelationalExpression > ShiftExpression  
    RelationalExpression <= ShiftExpression  
    RelationalExpression >= ShiftExpression  
    RelationalExpression instanceof ShiftExpression  
    RelationalExpression in ShiftExpression
```

Static Semantics: IsValidSimpleAssignmentTarget

```
RelationalExpression :  
  RelationalExpression < ShiftExpression  
  RelationalExpression > ShiftExpression  
  RelationalExpression <= ShiftExpression  
  RelationalExpression >= ShiftExpression  
  RelationalExpression instanceof ShiftExpression  
  RelationalExpression in ShiftExpression
```

1. Return false.

12.8.1 Runtime Semantics

Runtime Semantics: Evaluation

```
RelationalExpression : RelationalExpression < ShiftExpression  
1. Let `lref` be the result of evaluating `RelationalExpression`.  
2. Let `lval` be `GetValue(lref)`.  
3. `ReturnIfAbrupt(lval)`.  
4. Let `rref` be the result of evaluating `ShiftExpression`.  
5. Let `rval` be `GetValue(rref)`.  
6. Let `r` be the result of performing Abstract Relational Comparison `lval < rval` (see 7.2.8)  
7. `ReturnIfAbrupt(r)`.  
8. If `r` is `undefined`, return false. Otherwise, return `r`
```

```
RelationalExpression : RelationalExpression > ShiftExpression  
1. Let `lref` be the result of evaluating `RelationalExpression`.  
2. Let `lval` be `GetValue(lref)`.  
3. `ReturnIfAbrupt(lval)`.  
```
4. Let `lref` be the result of evaluating `RelationalExpression`.
5. Let `lval` be `GetValue(lref)`.
6. ReturnIfAbrupt(`lval`).
7. ReturnIfAbrupt(`rval`).
8. Return the result of `instanceof` operator `lval`, `rval`.

The abstract operation `instanceof` operator `(O, C)` implements the generic algorithm for determining if an object `O` inherits from the inheritance path defined by constructor `C`. This abstract operation performs the following steps:

1. If `Type(C)` is not `Object`, throw a `TypeError` exception.
2. Let `нст GENERIC` be the result of `GetMethod(C, @@hasInstance)`.
3. ReturnIfAbrupt(`нст GENERIC`).
4. If `нст GENERIC` is not `undefined`, then
   a. Let `result` be the result of calling the [[Call]] internal method of `нст GENERIC` passing `C` as `this` argument and a new List containing `O` as `argumentsList`.
   b. Return `ToBoolean(result)`.
5. If `IsCallable(C)` is `false`, then throw a `TypeError` exception.
6. Return the result of `OrdinaryHasInstance(C, O)`.

**NOTE** Steps 5 and 6 provide compatibility with previous editions of ECMAScript that did not use a `@@hasInstance` method to define the `instanceof` operator semantics. If a function object does not define or inherit `@@hasInstance` it uses the default `instanceof` semantics.
2. Let lval be GetValue(lref).
3. ReturnIfAbrupt(lval).
4. Let ref be the result of evaluating ShiftExpression.
5. Let rval be GetValue(ref).
6. ReturnIfAbrupt(rval).
7. If Type(rval) is not Object, throw a TypeError exception.
8. Return the result of HasProperty(rval, ToPropertyKey(lval)).

12.9 Equality Operators

NOTE The result of evaluating an equality operator is always of type Boolean, reflecting whether the relationship named by the operator holds between its two operands.

Syntax

EqualityExpression :
  RelationalExpression
  EqualityExpression == RelationalExpression
  EqualityExpression !== RelationalExpression
  EqualityExpression === RelationalExpression
  EqualityExpression !=== RelationalExpression

Static Semantics: IsValidSimpleAssignmentTarget

EqualityExpression :
  EqualityExpression == RelationalExpression
  EqualityExpression !== RelationalExpression
  EqualityExpression === RelationalExpression
  EqualityExpression !=== RelationalExpression

1. Return false.

12.9.1 Runtime Semantics

Runtime Semantics: Evaluation

EqualityExpression : EqualityExpression == RelationalExpression

1. Let lref be the result of evaluating EqualityExpression.
2. Let lval be GetValue(lref).
3. ReturnIfAbrupt(lval).
4. Let ref be the result of evaluating RelationalExpression.
5. Let rval be GetValue(ref).
6. ReturnIfAbrupt(rval).
7. Return the result of performing Abstract Equality Comparison rval == lval.

EqualityExpression : EqualityExpression !== RelationalExpression

1. Let lref be the result of evaluating EqualityExpression.
2. Let lval be GetValue(lref).
3. ReturnIfAbrupt(lval).
4. Let ref be the result of evaluating RelationalExpression.
5. Let rval be GetValue(ref).
6. ReturnIfAbrupt(rval).
7. Let r be the result of performing Abstract Equality Comparison rval == lval.
8. If r is true, return false. Otherwise, return true.

EqualityExpression : EqualityExpression === RelationalExpression

EqualityExpression : EqualityExpression !=== RelationalExpression

EqualityExpression : EqualityExpression === RelationalExpression

EqualityExpression : EqualityExpression !== RelationalExpression
1. Let lref be the result of evaluating EqualityExpression.
2. Let lval be GetValue(lref).
3. ReturnIfAbrupt(lval).
4. Let rref be the result of evaluating RelationalExpression.
5. Let rval be GetValue(rref).
6. ReturnIfAbrupt(rval).
7. Return the result of performing Strict Equality Comparison rval === lval.

EqualityExpression : EqualityExpression !== RelationalExpression

1. Let lref be the result of evaluating EqualityExpression.
2. Let lval be GetValue(lref).
3. ReturnIfAbrupt(lval).
4. Let rref be the result of evaluating RelationalExpression.
5. Let rval be GetValue(rref).
6. ReturnIfAbrupt(rval).
7. Let r be the result of performing Strict Equality Comparison rval === lval.
8. If r is true, return false. Otherwise, return true.

NOTE 1: Given the above definition of equality:
- String comparison can be forced by: "" + a == "" + b.
- Numeric comparison can be forced by: +a == +b.
- Boolean comparison can be forced by: !a == !b.

NOTE 2: The equality operators maintain the following invariants:
- A !== B is equivalent to !(A == B).
- A == B is equivalent to B == A, except in the order of evaluation of A and B.

NOTE 3: The equality operator is not always transitive. For example, there might be two distinct String objects, each representing the same string value; each String object would be considered equal to the string value by the == operator, but the two String objects would not be equal to each other. For example:
- new String("a") == "a" and "a" == new String("a") are both true.
- new String("a") !== new String("a") is false.

NOTE 4: Comparison of Strings uses a simple equality test on sequences of code unit values. There is no attempt to use the more complex, semantically oriented definitions of character or string equality and collating order defined in the Unicode specification. Therefore Strings values that are canonically equal according to the Unicode standard could test as unequal. In effect this algorithm assumes that both Strings are already in normalised form.

12.10 Binary Bitwise Operators

Syntax

BitwiseANDExpression :
EqualityExpression
BitwiseANDExpression & EqualityExpression

BitwiseXORExpression :
BitwiseANDExpression
BitwiseXORExpression ^ BitwiseANDExpression

BitwiseORExpression :
BitwiseXORExpression
BitwiseORExpression | BitwiseXORExpression

Static Semantics: isValidSimpleAssignmentTarget
BitwiseANDExpression : BitwiseANDExpression & EqualityExpression
BitwiseXORExpression : BitwiseXORExpression ^ BitwiseANDExpression
BitwiseORExpression : BitwiseORExpression | BitwiseXORExpression

1. Return false.

Runtime Semantics: Evaluation

The production \( A : A \ @ B \), where \( \@ \) is one of the bitwise operators in the productions above, is evaluated as follows:

1. Let \( lref \) be the result of evaluating \( A \).
2. Let \( lval \) be GetValue\((lref)\).
3. ReturnIfAbrupt\((lval)\).
4. Let \( rref \) be the result of evaluating \( B \).
5. Let \( rval \) be GetValue\((rref)\).
6. ReturnIfAbrupt\((rval)\).
7. Let \( lnum \) be ToInt32\((lval)\).
8. ReturnIfAbrupt\((lnum)\).
9. Let \( rnum \) be ToInt32\((rval)\).
10. ReturnIfAbrupt\((rnum)\).
11. Return the result of applying the bitwise operator \( \@ \) to \( lnum \) and \( rnum \). The result is a signed 32 bit integer.

12.11 Binary Logical Operators

Syntax

LogicalANDExpression : LogicalANDExpression && BitwiseORExpression
LogicalXORExpression : LogicalXORExpression || LogicalANDExpression

NOTE The value produced by a && or || operator is not necessarily of type Boolean. The value produced will always be the value of one of the two operand expressions.

Static Semantics: IsValidSimpleAssignmentTarget

LogicalANDExpression : LogicalANDExpression && BitwiseORExpression
LogicalORExpression : LogicalORExpression || LogicalANDExpression

1. Return false.

Runtime Semantics: Evaluation

LogicalANDExpression : LogicalANDExpression && BitwiseORExpression

1. Let \( lref \) be the result of evaluating LogicalANDExpression.
2. Let \( lval \) be GetValue\((lref)\).
3. Let \( lbool \) be ToBoolean\((lval)\).
4. ReturnIfAbrupt\((lbool)\).
5. If \( lbool \) is false, return \( lval \).
6. Let \( rref \) be the result of evaluating BitwiseORExpression.
7. Return GetValue\((rref)\).

LogicalORExpression : LogicalORExpression || LogicalANDExpression
12.12 Conditional Operator ( ? : )

Syntax

ConditionalExpression : LogicalORExpression LogicalORExpression ? AssignmentExpression : AssignmentExpression

NOTE The grammar for a ConditionalExpression in ECMA-Script is a little bit different from that in C and Java, which each allow the second subexpression to be an Expression but restrict the third expression to be a ConditionalExpression. The motivation for this difference in ECMA-Script is to allow an assignment expression to be governed by either arm of a conditional and to eliminate the confusing and fairly useless case of a comma expression as the centre expression.

Static Semantics: IsValidSimpleAssignmentTarget

ConditionalExpression : LogicalORExpression ? AssignmentExpression : AssignmentExpression
1. Return false.

Runtime Semantics: Evaluation

ConditionalExpression : LogicalORExpression ? AssignmentExpression : AssignmentExpression
1. Let lref be the result of evaluating LogicalORExpression.
2. Let lval be ToBoolean(GetValue(lref)).
3. ReturnIfAbrupt(lval).
4. If lval is true, then
   a. Let trueRef be the result of evaluating the first AssignmentExpression.
   b. Return GetValue(trueRef).
5. Else
   a. Let falseRef be the result of evaluating the second AssignmentExpression.
   b. Return GetValue(falseRef).

12.13 Assignment Operators

Syntax

AssignmentExpression : ConditionalExpression YieldExpression ArrowFunction

AssignmentOperator : one of *= /= += -= <<= >>= >>>= &= ^= |=

Static Semantics: Early Errors
AssignmentExpression : LeftHandSideExpression = AssignmentExpression

- It is a Syntax Error if LeftHandSideExpression is either an ObjectLiteral or an ArrayLiteral and if the lexical token sequence matched by LeftHandSideExpression cannot be parsed with no tokens left over using AssignmentPattern as the goal symbol.
- If LeftHandSideExpression is either an ObjectLiteral or an ArrayLiteral and if the lexical token sequence matched by LeftHandSideExpression can be parsed with no tokens left over using AssignmentPattern as the goal symbol then the following rules are not applied. Instead, the Early Error rules for AssignmentPattern are used.
- It is a Syntax Error if LeftHandSideExpression is an Identifier that can be statically determined to always resolve to a declarative environment record binding and the resolved binding is an immutable binding.
- It is an early Reference Error if LeftHandSideExpression is neither an ObjectLiteral nor an ArrayLiteral and IsValidSimpleAssignmentTarget of LeftHandSideExpression is false.

AssignmentExpression : LeftHandSideExpression AssignmentOperator AssignmentExpression

- It is a Syntax Error if the LeftHandSideExpression is an Identifier that can be statically determined to always resolve to a declarative environment record binding and the resolved binding is an immutable binding.
- It is an early Reference Error if IsValidSimpleAssignmentTarget of LeftHandSideExpression is false.

Static Semantics: IsValidSimpleAssignmentTarget
AssignmentExpression :
YieldExpression
ArrowFunction
LeftHandSideExpression = AssignmentExpression
LeftHandSideExpression AssignmentOperator AssignmentExpression

1. Return false.

12.13.2 Runtime Semantics
Runtime Semantics: Evaluation
AssignmentExpression : LeftHandSideExpression = AssignmentExpression

1. If LeftHandSideExpression is neither an ObjectLiteral nor an ArrayLiteral then
   a. Let lref be the result of evaluating LeftHandSideExpression.
   b. ReturnIfAbrupt(lref).
   c. Let ref be the result of evaluating AssignmentExpression.
   d. Let rval be GetValue(ref).
   e. Let status be PutValue(lref, rval).
   f. ReturnIfAbrupt(status).
   g. Return rval.
2. Let AssignmentPattern be the parse of the source code corresponding to LeftHandSideExpression using AssignmentPattern as the goal symbol.
3. Let rval be the result of evaluating AssignmentExpression.
4. Let rval be GetValue(rval).
5. ReturnIfAbrupt(rval).
6. If Type(rval) is not Object, then throw a TypeError exception.
7. Let status be the result of performing Destructuring Assignment Evaluation of AssignmentPattern using rval as the argument.
8. ReturnIfAbrupt(status).
9. Return rval.
1. Let lref be the result of evaluating LeftHandSideExpression.
2. Let lval be GetValue(lref).
3. ReturnIfAbrupt(lval).
4. Let rref be the result of evaluating AssignmentExpression.
5. Let rval be GetValue(rref).
6. ReturnIfAbrupt(rval).
7. Let operator be the @@ where AssignmentOperator is @@
8. Let r be the result of applying operator @@ to lval and rval.
9. Let status be PutValue(lref, r).
10. ReturnIfAbrupt(status).
11. Return r.

NOTE When an assignment occurs within strict mode code, it is a runtime error if lref in step 1.e of the first algorithm or step 9 of the second algorithm it is an unresolvable reference. If it is, a ReferenceError exception is thrown. The LeftHandSide also may not be a reference to a data property with the attribute value {[[Writable]]:false}, to an accessor property with the attribute value {[[Set]]:undefined}, nor to a non-existent property of an object for which the IsExtensible predicate returns the value false. In these cases a TypeError exception is thrown.

12.13.3 Destructuring Assignment

Supplemental Syntax

In certain circumstances when processing the production AssignmentExpression : LeftHandSideExpression = AssignmentExpression the following grammar is used to refine the interpretation of LeftHandSideExpression.

AssignmentPattern:
  ObjectAssignmentPattern
  ArrayAssignmentPattern

ObjectAssignmentPattern:
  { }
  { AssignmentPropertyList }
  { AssignmentPropertyList , }

ArrayAssignmentPattern:
  [ Elision opt AssignmentRestElement opt ]
  [ AssignmentElementList , Elision opt AssignmentRestElement opt ]

AssignmentPropertyList:
  AssignmentProperty
  AssignmentPropertyList , AssignmentProperty

AssignmentElementList:
  Elision opt AssignmentElement
  AssignmentElementList , Elision opt AssignmentElement

AssignmentProperty:
  Identifier Initialiser opt
 (PropertyName : AssignmentElement)

AssignmentElement:
  DestructuringAssignmentTarget Initialiser opt

AssignmentRestElement:
  . . . DestructuringAssignmentTarget

DestructuringAssignmentTarget:
  LeftHandSideExpression
12.13.3.1 Static Semantics

Static Semantics: Early Errors

AssignmentProperty : Identifier Initialiser

• It is a Syntax Error if Identifier is the Identifier eval or the Identifier arguments.
• It is a Syntax Error if Identifier does not statically resolve to a declarative environment record binding or if the resolved binding is an immutable binding.

AssignmentRestElement : ... RestElement

• It is a Syntax Error if IsValidSimpleAssignmentTarget of RestElement is false.

DestructuringAssignment : LeftHandSideExpression

• It is a Syntax Error if LeftHandSideExpression is either an ObjectLiteral or an ArrayLiteral and if the lexical token sequence matched by LeftHandSideExpression cannot be parsed with no tokens left over using AssignmentPattern as the goal symbol.
• It is a Syntax Error if LeftHandSideExpression is neither an ObjectLiteral nor an ArrayLiteral and IsValidSimpleAssignmentTarget of LeftHandSideExpression is false.
• It is a Syntax Error if LeftHandSideExpression is an Identifier that can be statically determined to always resolve to a declarative environment record binding and the resolved binding is an immutable binding.
• It is a Syntax Error if LeftHandSideExpression is the Identifier eval or the Identifier arguments.
• It is a Syntax Error if LeftHandSideExpression is a CoverParenthesisedExpressionAndArrowParameterList : ( Expression ) and Expression derives a production that would produce a Syntax Error according to these rules if that production is substituted for LeftHandSideExpression. This rule is recursively applied.

NOTE The last rule means that the other rules are applied even if multiple levels of nested parenthesis are surround Expression.

12.13.3.2 Runtime Semantics

Runtime Semantics: Destructuring Assignment Evaluation

with parameter obj

ObjectAssignmentPattern : { }
and
ArrayAssignmentPattern : [ ]

1. Return NormalCompletion(empty).

AssignmentPropertyList : AssignmentPropertyList , AssignmentProperty

1. Let status be the result of performing Destructuring Assignment Evaluation for AssignmentPropertyList using obj as the argument.
2. ReturnIfAbrupt(status).
3. Return the result of performing Destructuring Assignment Evaluation for AssignmentProperty using obj as the argument.

AssignmentProperty : Identifier Initialiser

1. Let P be StringValue of Identifier.
2. Let v be the result of calling Get(obj, P).
3. ReturnIfAbrupt(v).
4. If InitialiserOpt is present and v is undefined, then
   a. Let defaultValue be the result of evaluating Initialiser.
   b. Let v be ToObject(GetValue(defaultValue)).
5. ReturnIfAbrupt(v).
6. Let lref be the result of performing Identifier Resolution (8.3.1) with the IdentifierName corresponding to Identifier.

AssignmentProperty : PropertyName : AssignmentElement
1. Let name be the result of evaluating PropertyName.
2. ReturnIfAbrupt(name).
3. Return the result of performing Keyed Destructuring Assignment Evaluation of AssignmentElement with obj and name as the arguments.

ArrayAssignmentPattern : [ ElisionOpt AssignmentRestElement ]
1. Let skip be the Elision Width of Elision; if Elision is not present, use the numeric value zero.
2. Return the result of performing Indexed Destructuring Assignment Evaluation of AssignmentRestElement with obj and skip as the arguments.

ArrayAssignmentPattern : [ AssignmentElementList ]
1. Return the result of performing Indexed Destructuring Assignment Evaluation of AssignmentElementList using obj and 0 as the arguments.

ArrayAssignmentPattern : [ AssignmentElementList, ElisionOpt AssignmentRestElementOpt ]
1. Let lastIndex be the result of performing Indexed Destructuring Assignment Evaluation of AssignmentElementList with obj and 0 as the arguments.
2. Let skip be the Elision Width of Elision; if Elision is not present, use the numeric value zero.
3. If AssignmentRestElement is present, then return the result of performing Indexed Destructuring Assignment Evaluation of AssignmentRestElement with obj and lastIndex+skip as the arguments.
4. Return lastIndex.

Runtime Semantics: Indexed Destructuring Assignment Evaluation
with parameters obj and index
AssignmentElementList : ElisionOpt AssignmentElement
1. Let skip be the Elision Width of Elision; if Elision is not present, use the numeric value zero.
2. Let name be ToString(index+skip).
3. Let status be the result of performing Keyed Destructuring Assignment Evaluation of AssignmentElement with obj and name as the arguments.
4. ReturnIfAbrupt(status).
5. Return index+skip+1.

AssignmentElementList : AssignmentElementList, ElisionOpt AssignmentElement
1. Let listNext be the result of performing Indexed Destructuring Assignment Evaluation of AssignmentElementList using obj as the obj parameter and index as the index parameter.
2. Let skip be the Elision Width of Elision; if Elision is not present, use the numeric value zero.
3. ReturnIfAbrupt(listNext).
4. Let name be ToString(listNext+skip).
5. Let status be the result of performing Keyed Destructuring Assignment Evaluation of AssignmentElement with obj and name as the arguments.
6. ReturnIfAbrupt(status).
7. Return listNext+skip+1.

AssignmentRestElement: . . . DestructuringAssignmentTarget
1. Let lref be the result of evaluating DestructuringAssignmentTarget.
2. ReturnIfAbrupt(lref).
3. Let lenVal be the result of Get(obj, "length").
4. Let len be ToUint32(lenVal).
5. ReturnIfAbrupt(len).
6. Let A be the result of the abstract operation ArrayCreate with argument 0.
7. Let n=0;
8. Repeat, while index < len
   a. Let P be ToString(index).
   b. Let exists be the result of HasProperty(obj, P).
   c. ReturnIfAbrupt(exists).
   d. If exists is true, then
      i. Let v be the result of Get(obj, ToString(index)).
      ii. ReturnIfAbrupt(v).
      iii. Call the [[DefineOwnProperty]] internal method of A with arguments ToString(n) and Property Descriptor {
           [[Value]]: v, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}.
   e. Let n = n+1.
   f. Let index = index+1.

Runtime Semantics: Keyed Destructuring Assignment Evaluation
with parameters obj and propertyName
AssignmentElement: DestructuringAssignmentTarget Initialiseropt
1. Let exists be the result of HasProperty(obj, propertyName).
2. ReturnIfAbrupt(exists).
3. If exists is false, then
   a. If Initialiseropt is not present, then throw a TypeError exception.
   b. Else, let v be undefined.
4. Else,
   a. Let v be the result of Get(obj, propertyName).
   b. ReturnIfAbrupt(v).
5. If Initialiseropt is present and v is undefined, then
   a. Let defaultVal be the result of evaluating Initialiser.
   b. Let v be GetValue(defaultVal)
   c. ReturnIfAbrupt(v).
6. If DestructuringAssignmentTarget is an ObjectLiteral or an ArrayLiteral then
   a. Let AssignmentPattern be the parse of the source code corresponding to
      DestructuringAssignmentTarget using AssignmentPattern as the goal symbol
   b. If Type(v) is not Object, then throw a TypeError exception.
   c. Return the result of performing Destructuring Assignment Evaluation of AssignmentPattern with v as the argument.
7. Let lref be the result of evaluating DestructuringAssignmentTarget.
12.14 Comma Operator ( , )

Syntax
Expression :
   AssignmentExpression
   Expression , AssignmentExpression

Static Semantics: IsValidSimpleAssignmentTarget
Expression : Expression , AssignmentExpression
1. Return false.

Runtime Semantics: Evaluation
Expression : Expression , AssignmentExpression
1. Let lref be the result of evaluating Expression.
2. ReturnIfAbrupt(GetValue(lref))
3. Let rref be the result of evaluating AssignmentExpression.
4. Return GetValue(rref).

NOTE GetValue must be called even though its value is not used because it may have observable side-effects.

13 ECMAScript Language: Statements and Declarations

Syntax
Statement :
   BlockStatement
   VariableStatement
   EmptyStatement
   ExpressionStatement
   IfStatement
   BreakableStatement
   ContinueStatement
   BreakStatement
   ReturnStatement
   WithStatement
   LabelledStatement
   ThrowStatement
   TryStatement
   DebuggerStatement

Declaration :
   FunctionDeclaration
   GeneratorDeclaration
   ClassDeclaration
   LexicalDeclaration

BreakableStatement :
  IterationStatement
   SwitchStatement

Static Semantics

Static Semantics: VarDeclaredNames
Statement:
  EmptyStatement
  ExpressionStatement
  ContinueStatement
  BreakStatement
  ReturnStatement
  ThrowStatement
  DebuggerStatement

1. Return a new empty List.

Runtime Semantics:

Runtime Semantics: Labelled Evaluation

With argument labelSet.

BreakableStatement: IterationStatement

1. Let stmtResult be the result of performing Labelled Evaluation of IterationStatement with argument labelSet.
2. If stmtResult.[[type]] is break and stmtResult.[[target]] is empty, then
   a. If stmtResult.[[value]] is empty, then let stmtResult be NormalCompletion(undefined).
   b. Else, let stmtResult be NormalCompletion(stmtResult.[[value]])
3. Return stmtResult.

BreakableStatement: SwitchStatement

1. Let stmtResult be the result of evaluating SwitchStatement.
2. If stmtResult.[[type]] is break and stmtResult.[[target]] is empty, then
   a. If stmtResult.[[value]] is empty, then let stmtResult be NormalCompletion(undefined).
   b. Else, let stmtResult be NormalCompletion(stmtResult.[[value]])
3. Return stmtResult.

NOTE: A BreakableStatement is one that can be exited via an unlabelled BreakStatement.

Runtime Semantics: Evaluation

BreakableStatement: IterationStatement

1. Let newLabelSet be a new empty List.
2. Return the result of performing Labelled Evaluation of this BreakableStatement with argument newLabelSet.

13.1 Block

Syntax

BlockStatement: Block

Block:
  { StatementListopt }

StatementList:
  StatementListItem
  StatementList StatementListItem
13.1.1 Static Semantics

Static Semantics: Early Errors

Block : { StatementList }

- It is a Syntax Error if the LexicallyDeclaredNames of StatementList contains any duplicate entries.
- It is a Syntax Error if any element of the LexicallyDeclaredNames of StatementList also occurs in the VarDeclaredNames of StatementList.

Static Semantics: LexicalDeclarations

StatementList : StatementList StatementListItem

1. Let declarations be LexicalDeclarations of StatementList.
2. Append to declarations the elements of the LexicalDeclarations of StatementListItem.
3. Return declarations.

StatementListItem : Statement

1. Return a new empty List.

StatementListItem : Declaration

1. Return a new List containing Declaration.

Static Semantics: LexicallyDeclaredNames

Block : { }

1. Return a new empty List.

StatementList : StatementList StatementListItem

1. Let names be LexicallyDeclaredNames of StatementList.
2. Append to names the elements of the LexicallyDeclaredNames of StatementListItem.
3. Return names.

StatementListItem : Statement

1. Return a new empty List.

StatementListItem : Declaration

1. Return the BoundNames of Declaration.

Static Semantics: TopLevelLexicallyDeclaredNames

StatementList : StatementList StatementListItem

1. Let names be TopLevelLexicallyDeclaredNames of StatementList.
2. Append to names the elements of the TopLevelLexicallyDeclaredNames of StatementListItem.
3. Return names.

StatementListItem : Statement
1. Return a new empty List.

StatementList : Declaration

1. If Declaration is Statement : FunctionDeclaration, then return a new empty List.
2. Return the BoundNames of Declaration.

NOTE At the top level of a function, or script, function declarations are treated like var declarations rather than like lexical declarations.

Static Semantics: TopLevelLexicallyScopedDeclarations

StatementList : StatementList StatementListItem

1. Let declarations be TopLevelLexicallyScopedDeclarations of StatementList.
2. Append to declarations the elements of the TopLevelLexicallyScopedDeclarations of StatementListItem.
3. Return declarations.

StatementListItem : Statement

1. Return a new empty List.

StatementListItem : Declaration

1. If Declaration is Declaration : FunctionDeclaration, then return a new empty List.
2. Return the BoundNames of Declaration.

Static Semantics: TopLevelVarDeclaredNames

StatementList : StatementList StatementListItem

1. Let names be TopLevelVarDeclaredNames of StatementList.
2. Append to names the elements of the TopLevelVarDeclaredNames of StatementListItem.
3. Return names.

StatementListItem : Declaration

1. If Declaration is Declaration : FunctionDeclaration, then return the LexicallyDeclaredNames of Declaration.
2. Return a new empty List.

StatementListItem : Statement

1. Return VarDeclaredNames of Statement.

NOTE At the top level of a function or script, inner function declarations are treated like var declarations.

Static Semantics: TopLevelVarScopedDeclarations

StatementList : StatementList StatementListItem

1. Let declarations be TopLevelVarScopedDeclarations of StatementList.
2. Append to declarations the elements of the TopLevelVarScopedDeclarations of StatementListItem.
3. Return declarations.

StatementListItem : Statement

1. If Statement is Statement : VariableStatement, then return a new List containing VariableStatement.
2. Return a new empty List.
StatementListItem : Declaration

1. If Declaration is Declaration : FunctionDeclaration, then return a new List containing Declaration.
2. Return a new empty List.

Static Semantics: VarDeclaredNames

Block : { }

1. Return a new empty List.

StatementList : StatementList StatementListItem

1. Let names be VarDeclaredNames of StatementList.
2. Append to names the elements of the VarDeclaredNames of StatementListItem.
3. Return names.

StatementListItem : Declaration

1. Return a new empty List.

13.1.2 Runtime Semantics

Runtime Semantics: Evaluation

Block : { }  
1. Return NormalCompletion[undefined].

Block : { StatementList }

1. Let oldEnv be the running execution context’s LexicalEnvironment.
2. Let blockEnv be the result of calling NewDeclarativeEnvironment passing oldEnv as the argument.
3. Perform Block Declaration Instantiation using StatementList and blockEnv.
4. Set the running execution context’s LexicalEnvironment to blockEnv.
5. Set the running execution context’s LexicalEnvironment to oldEnv.
6. If blockValue.[[type]] is normal and blockValue.[[value]] is empty, then
   a. Return NormalCompletion[undefined].
7. Return blockValue.

NOTE No matter how control leaves the Block the LexicalEnvironment is always restored to its former state.

StatementList : StatementList StatementListItem

1. Let sl be the result of evaluating StatementList.
2. ReturnIfAbrupt(sl).
3. Let s be the result of evaluating StatementListItem.
4. If s.[[type]] is throw, return s.
5. If s.[[value]] is empty, let V = sl.[[value]], otherwise let V = s.[[value]].
6. Return Completion {{[[type]]: s.[[type]], [[value]]: V, [[target]]: s.[[target]]}}.

NOTE Steps 5 and 6 of the above algorithm ensure that the value of a StatementList is the value of the last value producing Statement in the StatementList. For example, the following calls to the eval function all return the value 1:

```javascript
 eval("1; ; ; ; ;;")
 eval("1;\{\}")
 eval("1;var a;")
```
13.1.2.1 Block Declaration Instantiation

NOTE When a Block or CaseBlock production is evaluated a new Declarative Environment Record is created and bindings for each block scoped variable, constant, or function declared in the block are instantiated in the environment record.

Block Declaration Instantiation is performed as follows using arguments code and env. code is the grammar production corresponding to the body of the block. env is the declarative environment record in which bindings are to be created.

Let declarations be the LexicalDeclarations of code.
2. Let functionsToInitialise be an empty List.
3. For each element d in declarations do
   a. For each element dn of the BoundNames of d do
      i. If IsConstantDeclaration of d is true, then
         1. Call env’s CreateImmutableBinding concrete method passing dn as the argument.
      ii. Else,
         1. Let status be the result of calling env’s CreateMutableBinding concrete method passing dn and false as the arguments.
         2. Assert: status is never an abrupt completion.
   b. If d is a GeneratorDeclaration production or a FunctionDeclaration production, then
      i. Append d to functionsToInitialise.
4. For each production f in functionsToInitialise, in list order do
   a. Let fn be the sole element of the BoundNames of f.
   b. Let fo be the result of performing InstantiateFunctionObject for f with argument env.
   c. Call env’s InitialiseBinding concrete method passing fn, and fo as the arguments.

13.2 Declarations and the Variable Statement

13.2.1 Let and Const Declarations

NOTE A let and const declarations define variables that are scoped to the running execution context’s LexicalEnvironment. The variables are created when their containing Lexical Environment is instantiated but may not be accessed in any way until the variable’s LexicalBinding is evaluated. A variable defined by a LexicalBinding with an Initialiser is assigned the value of its Initialiser's AssignmentExpression when the LexicalBinding is evaluated, not when the variable is created. If a LexicalBinding in a let declaration does not have an Initialiser the variable is assigned the value undefined when the LexicalBinding is evaluated.

Syntax
LexicalDeclaration : LetOrConst BindingList ;

LetOrConst : let const

BindingList : LexicalBinding
             BindingList , LexicalBinding

LexicalBinding : BindingIdentifier Initialiser opt
               BindingPattern Initialiser

BindingIdentifier : Identifier
13.2.1 Static Semantics

Static Semantics: Early Errors

LexicalBinding : BindingIdentifier

- It is a Syntax Error if IsConstantDeclaration of the LexicalDeclaration containing this production is true.

Commented [AWB870]: Consider disallowing undefined as a binding identifier in all new declaration forms.

BindingIdentifier : Identifier

- It is a Syntax Error if the BindingIdentifier is contained in strict code and if the Identifier is `eval` or `arguments`.

Static Semantics: BoundNames

LexicalDeclaration : LetOrConst BindingList ;

1. Return the BoundNames of BindingList.

BindingList : BindingList , LexicalBinding

1. Let names be the BoundNames of BindingList.
2. Append to names the elements of the BoundNames of LexicalBinding.
3. Return names.

LexicalBinding : BindingIdentifier Initialiseropt

1. Return the BoundNames of BindingIdentifier.

LexicalBinding : BindingPattern Initialiser

1. Return the BoundNames of BindingPattern.

BindingIdentifier : Identifier

1. Return a new List containing the StringValue of Identifier.

Static Semantics: IsConstantDeclaration

LexicalDeclaration : LetOrConst BindingList ;

1. Return IsConstantDeclaration of LetOrConst.

LetOrConst : let

1. Return false.

LetOrConst : const

1. Return true.

13.2.1.2 Runtime Semantics

Runtime Semantics: Binding Initialisation

With arguments `value` and `environment`. 
NOTE undefined is passed for environment to indicate that a PutValue operation should be used to assign the initialisation value. This is the case for var statements formal parameter lists of non-strict functions. In those cases a lexical binding is hosted and preinitialised prior to evaluation of its initialiser.

**BindingIdentifier : Identifier**

1. If environment is not undefined, then
   a. Let name be StringValue of Identifier.
   b. Let env be the environment record component of environment.
   c. Call the InitialiseBinding concrete method of env passing name and value as the arguments.
   d. Return NormalCompletion(undefined).
2. Else
   a. Let lhs be the result of evaluating Identifier as described in 12.1.2.
   b. Return PutValue(lhs, value).

**Runtime Semantics: Evaluation**

**LexicalDeclaration : LetOrConst BindingList ;**

1. Let next be the result of evaluating BindingList.
2. ReturnIfAbrupt(next).
3. Return NormalCompletion(empty).

**BindingList : BindingList , LexicalBinding**

1. Let next be the result of evaluating BindingList.
2. ReturnIfAbrupt(next).
3. Return the result of evaluating LexicalBinding.

**LexicalBinding : BindingIdentifier**

1. Let env be the running execution context’s LexicalEnvironment.
2. Return the result of performing Binding Initialisation for BindingIdentifier passing undefined and env as the arguments.

**LexicalBinding : BindingPattern Initialiser**

1. Let rhs be the result of evaluating Initialiser.
2. Let value be GetValue(rhs).
3. ReturnIfAbrupt(value).
4. Let env be the running execution context’s LexicalEnvironment.
5. Return the result of performing Binding Initialisation for BindingPattern using value and env as the arguments.

**LexicalBinding : BindingPattern Initialiser**

1. Let rhs be the result of evaluating Initialiser.
2. Let value be GetValue(rhs).
3. ReturnIfAbrupt(value).
4. If Type(value) is not Object, then throw a TypeError exception.
5. Let env be the running execution context’s LexicalEnvironment.
6. Return the result of performing Binding Initialisation for BindingPattern using value and env as the arguments.
13.2.2 Variable Statement

NOTE A var statement declares variables that are scoped to the running execution context’s VariableEnvironment. Var variables are created when their containing Lexical Environment is instantiated and are initialised to undefined when created. Within the scope of any VariableEnvironment a common Identifier may appear in more than one VariableDeclaration but those declarations collective define only one variable. A variable defined by a VariableDeclaration with an Initialiser is assigned the value of its Initialiser’s AssignmentExpression when the VariableDeclaration is executed, not when the variable is created.

Syntax

VariableStatement : var VariableDeclarationList ;

VariableDeclarationList : VariableDeclaration

VariableDeclaration : BindingIdentifier Initialiser opt

VariableDeclaration : BindingPattern Initialiser

13.2.2.1 Static Semantics

Static Semantics: BoundNames

VariableDeclarationList : VariableDeclarationList , VariableDeclaration

1. Let names be BoundNames of VariableDeclarationList.
2. Append to names the elements of BoundNames of VariableDeclaration.
3. Return names.

VariableDeclaration : BindingIdentifier Initialiser opt

1. Return the BoundNames of BindingIdentifier.

VariableDeclaration : BindingPattern Initialiser

1. Return the BoundNames of BindingPattern.

13.2.2.2 Runtime Semantics

Runtime Semantics: Binding Initialisation

With arguments value and environment.

NOTE undefined is passed for environment to indicate that a PutValue operation should be used to assign the initialisation value. This is the case for var statements formal parameter lists of non-strict functions. In those cases a lexical binding is hosted and preinitialised prior to evaluation of its initialiser.

VariableDeclaration : BindingIdentifier

1. Return the result of performing Binding Initialisation for BindingIdentifier passing value and undefined as the arguments.

VariableDeclaration : BindingIdentifier Initialiser

1. Return the result of performing Binding Initialisation for BindingIdentifier passing value and undefined as the arguments.
VariableDeclaration : BindingPattern Initialiser

1. Return the result of performing Binding Initialisation for BindingPattern passing value and undefined as the arguments.

Runtime Semantics: Evaluation

VariableStatement : var VariableDeclarationList ;

1. Let next be the result of evaluating VariableDeclarationList.
2. ReturnIfAbrupt(next).
3. Return NormalCompletion(empty).

VariableDeclarationList : VariableDeclarationList , VariableDeclaration

1. Let next be the result of evaluating VariableDeclarationList.
2. Return the result of evaluating VariableDeclaration.

VariableDeclaration : BindingIdentifier

1. Return NormalCompletion(empty).

VariableDeclaration : BindingIdentifier Initialiser

1. Let rhs be the result of evaluating Initialiser.
2. Let value be GetValue(rhs).
3. ReturnIfAbrupt(value).
4. Return the result of performing Binding Initialisation for BindingIdentifier passing value and undefined as the arguments.

NOTE If a VariableDeclaration is nested within a with statement and the Identifier in the VariableDeclaration is the same as a property name of the binding object of the with statement’s object environment record, then step 3 will assign value to the property instead of to the VariableEnvironment binding of the Identifier.

VariableDeclaration : BindingPattern Initialiser

1. Let rhs be the result of evaluating Initialiser.
2. Let rval be GetValue(rhs).
3. ReturnIfAbrupt(rval).
4. If Type(rval) is not Object, then throw a TypeError exception.
5. Return the result of performing Binding Initialisation for BindingPattern passing rval and undefined as arguments.

13.2.3 Destructuring Binding Patterns

Syntax

BindingPattern : ObjectBindingPattern
ArrayBindingPattern

ObjectBindingPattern :
   { }
   { BindingPropertyList }
   { BindingPropertyList , }
ArrayBindingPattern:
  [ Elisionopt BindingRestElementopt ]
  [ BindingElementList ]
  [ BindingElementList , Elisionopt BindingRestElementopt ]

BindingPropertyList:
  BindingProperty
  BindingPropertyList , BindingProperty

BindingElementList:
  Elisionopt BindingElement
  BindingElementList , Elisionopt BindingElement

BindingProperty:
  SimpleNameBinding
  PropertyName BindingElement

BindingElement:
  SimpleNameBinding
  BindingPattern Initialiseropt

SimpleNameBinding:
  BindingIdentifier Initialiseropt

BindingRestElement:
  ...

13.2.3.1 Static Semantics

Static Semantics: Early Errors

BindingPattern : ObjectBindingPattern
  • It is a Syntax Error if the BoundNames of ObjectBindingPattern contains the string "eval" or the string "arguments".

BindingPattern : ArrayBindingPattern
  • It is a Syntax Error if the BoundNames of ArrayBindingPattern contains the string "eval" or the string "arguments".

Static Semantics: BoundNames

ObjectBindingPattern : { }
1. Return an empty List.

ArrayBindingPattern : [ ]
1. Return an empty List.

ArrayBindingPattern : [ Elisionopt BindingRestElement ]
1. Return the BoundNames of BindingRestElement.

ArrayBindingPattern : [ BindingElementList , Elisionopt ]
1. Return the BoundNames of BindingElementList.

Commented [AWB1671]: Note that this may be a computed property name
ArrayBindingPattern : [ BindingElementList , Elisionopt BindingRestElement ]
1. Let names be BoundNames of BindingElementList.
2. Append to names the elements of BoundNames of BindingRestElement.
3. Return names.

BindingPropertyList : BindingPropertyList , BindingProperty
1. Let names be BoundNames of BindingPropertyList.
2. Append to names the elements of BoundNames of BindingProperty.
3. Return names.

BindingElementList : Elisionopt BindingElement
1. Return BoundNames of BindingElement.

BindingElementList : BindingElementList , Elisionopt BindingElement
1. Let names be BoundNames of BindingElementList.
2. Append to names the elements of BoundNames of BindingElement.
3. Return names.

BindingProperty : PropertyName : BindingElement
1. Return the BoundNames of BindingElement.

SingleNameBinding : BindingIdentifier Initialiseropt
1. Return the BoundNames of BindingIdentifier.

BindingElement : BindingPattern Initialiseropt
1. Return the BoundNames of BindingPattern.

Static Semantics: HasInitialiser

BindingElement : BindingPattern
1. Return false.

BindingElement : BindingPattern Initialiser
1. Return true.

SingleNameBinding : BindingIdentifier
1. Return false.

SingleNameBinding : BindingIdentifier Initialiser
1. Return true.

13.2.3.2 Runtime Semantics

Runtime Semantics: Binding Initialisation

With parameters value and environment.
NOTE When `undefined` is passed for `environment` it indicates that a `PutValue` operation should be used to assign the initialisation value. This is the case for formal parameter lists of non-strict functions. In that case the formal parameter bindings are preinitialised in order to deal with the possibility of multiple parameters with the same name.

**BindingPattern : ObjectBindingPattern**

1. Assert: Type(`value`) is `Object`
2. Return the result of performing Binding Initialisation for `ObjectBindingPattern` using `value` and `environment` as arguments.

**BindingPattern : ArrayBindingPattern**

1. Assert: Type(`value`) is `Object`
2. Return the result of performing Indexed Binding Initialisation for `ArrayBindingPattern` using `value`, `0`, and `environment` as arguments.

**ObjectBindingPattern : { }**

1. Return `NormalCompletion(EMPTY)`.

**BindingPropertyList : BindingPropertyList , BindingProperty**

1. Let `status` be the result of performing Binding Initialisation for `BindingPropertyList` using `value` and `environment` as arguments.
2. ReturnIfAbrupt(`status`).
3. Return the result of performing Keyed Binding Initialisation for `BindingProperty` using `value`, `environment`, and `name` as the arguments.

**BindingProperty : SingleNameBinding**

1. Let `name` be the string that is the only element of `BoundNames` of `SingleNameBinding`.
2. Return the result of performing Keyed Binding Initialisation for `SingleNameBinding` using `value`, `environment`, and `name` as the arguments.

**BindingProperty : PropertyName : BindingElement**

1. Let `P` be the result of evaluating `PropertyName`
2. ReturnIfAbrupt(`P`).
3. Return the result of performing Keyed Binding Initialisation for `BindingElement` using `value`, `environment`, and `name` and `P` as arguments.

**Runtime Semantics: Indexed Binding Initialisation**

With parameters `array`, `nextIndex`, and `environment`.

NOTE When `undefined` is passed for `environment` it indicates that a `PutValue` operation should be used to assign the initialisation value. This is the case for formal parameter lists of non-strict functions. In that case the formal parameter bindings are preinitialised in order to deal with the possibility of multiple parameters with the same name.

**ArrayBindingPattern : [ Elision_opt ]**

1. Return `NormalCompletion(EMPTY)`.

**ArrayBindingPattern : [ Elision_opt , BindingRestElement ]**

1. Let `nextIndex` be the Elision Width of `Elision`; if `Elision` is not present, use the numeric value zero.
2. Return the result of performing Indexed Binding Initialisation for `BindingRestElement` using `array`, `nextIndex`, and `environment` as arguments.
ArrayBindingPattern: [ BindingElementList ]

1. Return the result of performing Indexed Binding Initialisation for BindingElementList using array, nextIndex, and environment as arguments.

ArrayBindingPattern: [ BindingElementList, Elisionopt ]

1. Return the result of performing Indexed Binding Initialisation for BindingElementList using array, nextIndex, and environment as arguments.

ArrayBindingPattern: [ BindingElementList, Elisionopt BindingRestElement ]

1. Let next be the result of performing Indexed Binding Initialisation for BindingElementList using array, nextIndex, and environment as arguments.
2. ReturnIfAbrupt(next).
3. Let skip be the Elision Width of Elision; if Elision is not present, use the numeric value zero.
4. Return the result of performing Indexed Binding Initialisation for BindingRestElement using array, next + skip, and environment as arguments.

BindingElementList: Elisionopt BindingElement

1. Let skip be the Elision Width of Elision; if Elision is not present, use the numeric value zero.
2. Let status be the result of performing Indexed Binding Initialisation for BindingElement using array, nextIndex + skip, and environment as arguments.
3. ReturnIfAbrupt(status).
4. Return nextIndex + skip + 1.

BindingElementList: BindingElementList, Elisionopt BindingElement

1. Let listNext be the result of performing Indexed Binding Initialisation for BindingElementList using array, nextIndex, and environment as arguments.
2. ReturnIfAbrupt(listNext).
3. Let skip be the Elision Width of Elision; if Elision is not present, use the numeric value zero.
4. Let status be the result of performing Indexed Binding Initialisation for BindingElement using array, listNext + skip, and environment as arguments.
5. ReturnIfAbrupt(status).
6. Return listNext + skip + 1.

BindingElement: SingleNameBinding

1. Return the result of performing Keyed Binding Initialisation for SingleNameBinding using array, environment, and ToString(nextIndex) as the arguments.

BindingElement: BindingPattern Initialiseropt

1. Let P be ToString(nextIndex).
2. Let exists be the result of HasProperty(obj, P).
3. ReturnIfAbrupt(exists).
4. If exists is false, then
   a. If Initialiseropt is not present, then throw a TypeError exception.
   b. Else, let v be undefined.
5. Else,
   a. Let v be the result of Get(array, P).
   b. ReturnIfAbrupt(v).
6. If Initialiseropt is present and v is undefined, then
   a. Let defaultValue be the result of evaluating Initialiser.
   b. Let v be GetValue(defaultValue).
   c. ReturnIfAbrupt(v).
7. If Type(v) is not Object, then throw a TypeError exception.
7. Return the result of performing Binding Initialisation for BindingPattern passing v and environment as arguments.

**BindingRestElement**: . . . BindingIdentifier

1. Let A be the result of the abstract operation ArrayCreate with argument 0.
2. Let lenVal be the result of Get(array, "length").
3. Let arrayLength be ToLength(lenVal).
4. ReturnIfAbrupt(arrayLength).
5. Let n=0.
6. Let index = nextIndex.
7. Repeat, while index < arrayLength
   a. Let P be ToString(index).
   b. Let exists be the result of HasProperty(array, P).
   c. ReturnIfAbrupt(exists).
   d. If exists is true, then
      i. Let v be the result of Get(array, P).
      ii. ReturnIfAbrupt(v).
   e. Let n = n+1.
   f. Let index = index+1.
8. Return the result of performing Binding Initialisation for BindingIdentifier using A and environment as arguments.

**Runtime Semantics: Keyed Binding Initialisation**

1. Let exists be the result of HasProperty(obj, propertyName).
2. ReturnIfAbrupt(exists).
3. If exists is false, then
   a. If Initialiser is not present, then throw a TypeError exception.
   b. Else, let v be undefined.
4. Else,
   a. Let v be the result of Get(obj, propertyName).
   b. ReturnIfAbrupt(v).
5. If Initialiser is present and v is undefined, then
   a. Let defaultValue be the result of evaluating Initialiser.
   b. Let v be GetValue(defaultValue).
   c. ReturnIfAbrupt(v).
6. If Type(v) is not Object, then throw a TypeError exception.
7. Return the result of performing Binding Initialisation for BindingPattern passing v and environment as arguments.

**SingleNameBinding** : BindingIdentifier Initialiser, opt

1. Let exists be the result of HasProperty(obj, propertyName).
2. ReturnIfAbrupt(exists).
3. If exists is false, then
   a. If Initialiser is not present, then throw a TypeError exception.
   b. Else, let v be undefined.
4. Else,
a. Let v be the result of Get(obj, propertyName).
b. ReturnIfAbrupt(v).

5. If Initialiseropt is present and v is undefined, then
   a. Let defaultValue be the result of evaluating Initialiser.
   b. Let v be GetValue(defaultValue).
   c. ReturnIfAbrupt(v).

6. Return the result of performing Binding Initialisation for BindingIdentifier passing v and environment as arguments.

13.3 Empty Statement

Syntax
EmptyStatement: ;

13.3.1 Runtime Semantics

Runtime Semantics: Evaluation
EmptyStatement: ;
1. Return NormalCompletion(empty).

13.4 Expression Statement

Syntax
ExpressionStatement: [lookahead \[\{, function, class \]}] Expression ;

NOTE: An ExpressionStatement cannot start with an opening curly brace because that might make it ambiguous with a Block. Also, an ExpressionStatement cannot start with the function or class keywords because that would make it ambiguous with a FunctionDeclaration, a GeneratorDeclaration, or a ClassDeclaration.

13.4.1 Runtime Semantics

Runtime Semantics: Evaluation
ExpressionStatement: [lookahead \[\{, function, class \]}] Expression ;
1. Let exprRef be the result of evaluating Expression.
2. Let value be GetValue(exprRef).
3. ReturnIfAbrupt(value).
4. Return NormalCompletion(value).

13.5 The if Statement

Syntax
IfStatement: if ( Expression ) Statement else Statement
   if ( Expression ) Statement

Each else for which the choice of associated if is ambiguous shall be associated with the nearest possible if that would otherwise have no corresponding else.

Static Semantics: VarDeclaredNames

IfStatement: if ( Expression ) Statement else Statement
1. Let names be VarDeclaredNames of the first Statement.
2. Append to names the elements of the VarDeclaredNames of the second Statement.
3. Return names.

IfStatement: if (Expression) Statement
1. Return the VarDeclaredNames of Statement.

13.5.1 Runtime Semantics

Runtime Semantics: Evaluation

IfStatement: if (Expression) Statement else Statement
1. Let exprRef be the result of evaluating Expression.
2. Let exprValue be ToBoolean(GetValue(exprRef)).
3. ReturnIfAbrupt(exprValue).
4. If exprValue is true, then
   a. Let stmtValue be the result of evaluating the first Statement.
5. Else,
   a. Let stmtValue be the result of evaluating the second Statement.
6. If stmtValue.[[type]] is normal and stmtValue.[[value]] is empty, then
   a. Return NormalCompletion(undefined).
7. Return stmtValue.

IfStatement: if (Expression) Statement
1. Let exprRef be the result of evaluating Expression.
2. Let exprValue be ToBoolean(GetValue(exprRef)).
3. ReturnIfAbrupt(exprValue).
4. If exprValue is false, then
   a. Return NormalCompletion(undefined).
5. Else,
   a. Let stmtValue be the result of evaluating Statement.
6. If stmtValue.[[type]] is normal and stmtValue.[[value]] is empty, then
   a. Return NormalCompletion(undefined).
7. Return stmtValue.

13.6 Iteration Statements

Syntax

IterationStatement:
do Statement while (Expression) ; opt
while (Expression) Statement
for (var VariableDeclarationList; Expressionopt; Expressionopt) Statement
for (LexicalDeclaration; Expressionopt; Expressionopt) Statement
for (var VariableDeclarationList in Expression) Statement
for (var ForBinding in Expression) Statement
for (var ForBinding of AssignmentExpression) Statement
for (var ForBinding of AssignmentExpression) Statement
for (ForDeclaration in Expression) Statement
for (ForDeclaration of AssignmentExpression) Statement
for (ForDeclaration of AssignmentExpression) Statement

ForDeclaration:
LetOrConst ForBinding

NOTE 1  ForBinding is defined in 12.1.4.2.
A semicolon is not required after a do-while statement.

**Runtime Semantics**

**LoopContinues Abstract Operation**

The abstract operation LoopContinues with arguments completion and labelSet is defined by the following step:

1. If completion.type is normal, then return true.
2. If completion.type is not continue, then return false.
3. If completion.target is empty, then return true.
4. If completion.target is an element of labelSet, then return true.
5. Return false.

**NOTE** Within the Statement part of an IterationStatement a ContinueStatement may be used to begin a new iteration.

### 13.6.1 The do-while Statement

**Static Semantics:** VarDeclaredNames

IterationStatement: `do` Statement while (Expression) ;

1. Return the VarDeclaredNames of Statement.

**Runtime Semantics**

**Labelled Evaluation**

With argument labelSet.

IterationStatement: `do` Statement while (Expression) ;

1. Let `V = undefined`.
2. Repeat
   a. Let `stmt` be the result of evaluating Statement.
   b. If `stmt.value` is not empty, let `V = stmt.value`.
   c. If `stmt` is an abrupt completion and LoopContinues (stmt, labelSet) is false, return stmt.
   d. Let `exprRef` be the result of evaluating Expression.
   e. Let `exprValue` be ToBoolean(GetValue(exprRef)).
   f. If `exprValue` is false, Return NormalCompletion(V).
   g. Else if `exprValue` is not true, then
      i. Assert: `exprValue` is an abrupt completion.
      ii. If LoopContinues (exprValue,labelSet) is false, return exprValue.

### 13.6.2 The while Statement

**Static Semantics:** VarDeclaredNames

IterationStatement: `while` (Expression) Statement

1. Return the VarDeclaredNames of Statement.

**Runtime Semantics**

**Labelled Evaluation**

With argument labelSet.

IterationStatement: `while` (Expression) Statement
1. Let \( V = \text{undefined} \).
2. Repeat
   a. Let \( \text{exprRef} \) be the result of evaluating \( \text{Expression} \).
   b. Let \( \text{exprValue} \) be \( \text{ToBoolean(GetValue(\text{exprRef})}) \).
   c. If \( \text{exprValue} \) is \( \text{false} \), return NormalCompletion(\( V \)).
   d. If \( \text{exprValue} \) is not \text{true}, then
      i. Assert: \( \text{exprValue} \) is an abrupt completion.
      ii. If LoopContinues(\( \text{exprValue} \), \( \text{labelSet} \)) is \text{false}, return \( \text{exprValue} \).
   e. Let \( \text{stmt} \) be the result of evaluating \( \text{Statement} \).
   f. If \( \text{stmt} \).[\( \text{value} \]) is not \text{empty}, let \( V = \text{stmt} \).[\( \text{value} \])
   g. If LoopContinues(\( \text{stmt} \), \( \text{labelSet} \)) is \text{false}, return \( \text{stmt} \).

13.6.3 The for Statement

13.6.3.1 Static Semantics

Static Semantics: \text{VarDeclaredNames}

\text{IterationStatement}: \text{for} \ ( \text{Expression}\_\text{opt} ; \text{Expression}\_\text{opt} ; \text{Expression}\_\text{opt} ) \ \text{Statement}

1. Return the \text{VarDeclaredNames} of \text{Statement}.

\text{IterationStatement}: \text{for} \ ( \text{var} \ \text{VariableDeclarationList} ; \text{Expression}\_\text{opt} ; \text{Expression}\_\text{opt} ) \ \text{Statement}

1. Let \( \text{names} \) be \text{BoundNames} of \text{VariableDeclarationList}.
2. Append to \( \text{names} \) the elements of the \text{VarDeclaredNames} of \text{Statement}.
3. Return \( \text{names} \).

\text{IterationStatement}: \text{for} \ ( \text{LexicalDeclaration} ; \text{Expression}\_\text{opt} ; \text{Expression}\_\text{opt} ) \ \text{Statement}

1. Return the \text{VarDeclaredNames} of \text{Statement}.

13.6.3.2 Runtime Semantics

Runtime Semantics: Labelled Evaluation

With argument \( \text{labelSet} \).

\text{IterationStatement}: \text{for} \ ( \text{Expression}\_\text{opt} ; \text{Expression}\_\text{opt} ; \text{Expression}\_\text{opt} ) \ \text{Statement}

1. If \( \text{Expression} \) is present, then
   a. Let \( \text{exprRef} \) be the result of evaluating \( \text{Expression} \).
   b. Let \( \text{exprValue} \) be \( \text{GetDefaultValue(\text{exprRef})} \).
      c. If LoopContinues(\( \text{exprValue} \), \( \text{labelSet} \)) is \text{false}, return \( \text{exprValue} \).
   2. Return the result of performing For Body Evaluation with the first \( \text{Expression} \) as the \text{testExpr} argument, the second \( \text{Expression} \) as the \text{incrementExpr} argument, \text{Statement} as the \text{stmt} argument, and with \( \text{labelSet} \).

\text{IterationStatement}: \text{for} \ ( \text{var} \ \text{VariableDeclarationList} ; \text{Expression}\_\text{opt} ; \text{Expression}\_\text{opt} ) \ \text{Statement}

1. Let \( \text{varDcl} \) be the result of evaluating \text{VariableDeclarationList}.
2. If LoopContinues(\( \text{varDcl} \), \( \text{labelSet} \)) is \text{false}, return \( \text{varDcl} \).
3. Return the result of performing For Body Evaluation with the first \( \text{Expression} \) as the \text{testExpr} argument, the second \( \text{Expression} \) as the \text{incrementExpr} argument, \text{Statement} as the \text{stmt} argument, and with \( \text{labelSet} \).

\text{IterationStatement}: \text{for} \ ( \text{LexicalDeclaration} ; \text{Expression}\_\text{opt} ; \text{Expression}\_\text{opt} ) \ \text{Statement}

1. Let \( \text{oldEnv} \) be the running execution context’s \text{LexicalEnvironment}.
2. Let \( \text{loopEnv} \) be the result of calling \text{NewDeclarativeEnvironment} passing \( \text{oldEnv} \) as the argument.
3. Let \( \text{isConst} \) be the result of performing \text{IsConstantDeclaration of LexicalDeclaration}.

**Commented [AWB679]:** ES5 breaking change: completion return

**Commented [AWB680]:** Break/continue/return in the expression works normally (future for do {} or block lambda expressions)

**Commented [AWB381]:** The lexical scoping of for iteration variables still needs to be taken care of

**Commented [AWB682]:** A final decision has not yet been reached on the scoping semantics used for this form of for statement. This version uses “loop scoping” a single set of let/const bindings are used for all iterations of the loop. This is the simplest of the semantics under consideration.
4. For each element dn of the BoundNames of LexicalDeclaration do
   a. If Const is true, then
      i. Call loopEnv’s CreateImmutableBinding concrete method passing dn as the argument.
   b. Else,
      i. Call loopEnv’s CreateMutableBinding concrete method passing dn and false as the arguments.
      ii. Assert: The above call to CreateMutableBinding will never return an abrupt completion.
5. Set the running execution context’s LexicalEnvironment to loopEnv.
6. Let forDel be the result of evaluating LexicalDeclaration.
7. If LoopContinues(forDel,labelSet) is false, then
   a. Set the running execution context’s LexicalEnvironment to oldEnv.
   b. Return forDel.
8. Let bodyResult be the result of performing For Body Evaluation with the first Expr as the testExpr argument, the second Expr as the incExpr argument, Statement as the stmt argument, and with labelSet.
9. Set the running execution context’s LexicalEnvironment to oldEnv.
10. Return bodyResult.

Runtime Semantics: For Body Evaluation Abstract Operation

The abstract operation For Body Evaluation with arguments testExpr, incrementExpr, stmt, and labelSet is performed as follows:

1. Let V = undefined
2. Repeat
   a. If testExpr is not (empty), then
      i. Let testExprRef be the result of evaluating testExpr.
      ii. Let testExprValue be ToObject(GetValue(testExprRef)).
      iii. If testExprValue is false, return NormalCompletion(V).
      iv. Else if LoopContinues(testExprValue,labelSet) is false, return testExprValue.
   b. Let result be the result of evaluating stmt.
   c. If result.[value] is not empty, let V = result.[value].
   d. If LoopContinues(result,labelSet) is false, return result.
   e. If incrementExpr is not (empty), then
      i. Let incExprRef be the result of evaluating incrementExpr.
      ii. Let incExprValue be GetValue(incExprRef).
      iii. If LoopContinues/incExprValue,labelSet is false, return incExprValue.

13.6.4 The for-in and for/of Statements

13.6.4.1 Static Semantics

IterationStatement:

for (LeftHandSideExpression in Expression) Statement
for (LeftHandSideExpression of AssignmentExpression) Statement

- It is a Syntax Error if LeftHandSideExpression is either an ObjectLiteral or an ArrayLiteral and if the lexical token sequence matched by LeftHandSideExpression cannot be parsed with no tokens left over using AssignmentPattern as the goal symbol.
- If LeftHandSideExpression is either an ObjectLiteral or an ArrayLiteral and if the lexical token sequence matched by LeftHandSideExpression can be parsed with no tokens left over using AssignmentPattern as the goal symbol then the following rules are not applied. Instead, the Early Error rules for AssignmentPattern are used.
- It is a Syntax Error if LeftHandSideExpression is an Identifier that can be statically determined to always resolve to a declarative environment record binding and the resolved binding is an immutable binding.
- It is a Syntax Error if LeftHandSideExpression is neither an ObjectLiteral nor an ArrayLiteral and IsValueSimpleAssignmentTarget of LeftHandSideExpression is false.
• It is a Syntax Error if the LeftHandSideExpression is 
CoverParenthesisedExpressionAndArrowParameterList : { Expression } 
and Expression derives a production that would produce a Syntax Error according to these rules if that 
production is substituted for LeftHandSideExpression. This rule is recursively applied.

NOTE The last rule means that the other rules are applied even if multiple levels of nested parentheses surround 
Expression.

IterationStatement : 
for (ForDeclaration in Expression ) Statement
for (ForDeclaration of AssignmentExpression ) Statement
• It is a Syntax Error if any element of the BoundNames of ForDeclaration also occurs in the 
VarDeclaredNames of Statement.

Static Semantics: BoundNames
ForDeclaration : LetOrConst ForBinding
1. Return the BoundNames of ForBinding.

Static Semantics: VarDeclaredNames
IterationStatement : for ( LeftHandSideExpression in Expression ) Statement
1. Return the VarDeclaredNames of Statement.
IterationStatement : for ( var ForBinding in Expression ) Statement
1. Let names be the BoundNames of ForBinding.
2. Append to names the elements of the VarDeclaredNames of Statement.
3. Return names
IterationStatement : for ( ForDeclaration in Expression ) Statement
1. Return the VarDeclaredNames of Statement.
IterationStatement : for ( LeftHandSideExpression of AssignmentExpression ) Statement
1. Return the VarDeclaredNames of Statement.
IterationStatement : for ( var ForBinding of AssignmentExpression ) Statement
1. Let names be the BoundNames of ForBinding.
2. Append to names the elements of the VarDeclaredNames of Statement.
3. Return names
IterationStatement : for ( ForDeclaration of AssignmentExpression ) Statement
1. Return the VarDeclaredNames of Statement.

13.6.4.2 Runtime Semantics

Runtime Semantics: Binding Instantiation

With arguments value and environment.
ForDeclaration : LetOrConst ForBinding
1. For each element `name` of the `BoundNames` of `ForBinding` do
   a. If `IsConstantDeclaration of LetOrConst` is `false`, then
      i. Call `environment`’s `CreateMutableBinding` concrete method with argument `name`.
      ii. Assert: The above call to `CreateMutableBinding` will never return an abrupt completion.
   b. Else,
      i. Call `environment`’s `CreateImmutableBinding` concrete method with argument `name`.
2. Return the result of performing Binding Initialisation for `ForBinding` passing `value` and `environment` as the arguments.

**Runtime Semantics: Labelled Evaluation**

With argument `labelSet`.

**IterationStatement**: `for (LeftHandSideExpression in Expression) Statement`

1. Let `keyResult` be the result of performing For In/Of Expression Evaluation with `Expression`, `enumerate`, and `labelSet`.
2. ReturnIfAbrupt(`keyResult`).
3. Return the result of performing For In/Of Body Evaluation with `LeftHandSideExpression`, `Statement`, `keyResult`, `assignment`, and `labelSet`.

**IterationStatement**: `for (var ForBinding in Expression) Statement`

1. Let `keyResult` be the result of performing For In/Of Expression Evaluation with `Expression`, `enumerate`, and `labelSet`.
2. ReturnIfAbrupt(`keyResult`).
3. Return the result of performing For In/Of Body Evaluation with `ForBinding`, `Statement`, `keyResult`, `varBinding`, and `labelSet`.

**IterationStatement**: `for (ForDeclaration in Expression) Statement`

1. Let `keyResult` be the result of performing For In/Of Expression Evaluation with `Expression`, `enumerate`, and `labelSet`.
2. ReturnIfAbrupt(`keyResult`).
3. Return the result of performing For In/Of Body Evaluation with `ForDeclaration`, `Statement`, `keyResult`, `lexicalBinding`, and `labelSet`.

**IterationStatement**: `for (LeftHandSideExpression of AssignmentExpression) Statement`

1. Let `keyResult` be the result of performing For In/Of Expression Evaluation with `AssignmentExpression`, `iterate`, and `labelSet`.
2. ReturnIfAbrupt(`keyResult`).
3. Return the result of performing For In/Of Body Evaluation with `LeftHandSideExpression`, `Statement`, `keyResult`, `assignment`, and `labelSet`.

**IterationStatement**: `for (var ForBinding of AssignmentExpression) Statement`

1. Let `keyResult` be the result of performing For In/Of Expression Evaluation with `AssignmentExpression`, `iterate`, and `labelSet`.
2. ReturnIfAbrupt(`keyResult`).
3. Return the result of performing For In/Of Body Evaluation with `ForBinding`, `Statement`, `keyResult`, `varBinding`, and `labelSet`.

**IterationStatement**: `for (ForDeclaration of AssignmentExpression) Statement`

1. Let `keyResult` be the result of performing For In/Of Expression Evaluation with `AssignmentExpression`, `iterate`, and `labelSet`.
2. ReturnIfAbrupt(`keyResult`).
3. Return the result of performing For In/Of Body Evaluation with `ForDeclaration`, `Statement`, `keyResult`, `assignment`, and `labelSet`.

© Ecma International 2013
3. Return the result of performing For In/Of Body Evaluation with ForDeclaration, Statement, keyResult, lexicalBinding, and labelSet.

Runtime Semantics: For In/Of Expression Evaluation Abstract Operation

The abstract operation For In/Of Expression Evaluation is called with arguments expr, iterationKind, and labelSet. The value of iterationKind is either enumerate or iterate.

1. Let exprRef be the result of evaluating the production that is expr.
2. Let exprValue be GetValue(exprRef).
3. If exprValue is an abrupt completion,
   a. If LoopContinues(exprValue,labelSet) is false, then return exprValue.
   b. Else, return Completion({[[type]]: break, [[value]]: empty, [[target]]: empty}).
4. If exprValue.[[value]] is null or undefined, return Completion({[[type]]: break, [[value]]: empty, [[target]]: empty}).
5. Let obj be ToObject(exprValue).
6. If iterationKind is enumerate, then
   a. Let keys be the result of calling the [[Enumerate]] internal method of obj with no arguments.
   b. Else, Assert iterationKind is iterate.
   c. Let iterator be the result of performing Invoke with arguments obj, @@iterator and an empty List.
   d. Let keys be ToObject(iterator).
7. If keys is an abrupt completion, then
   a. If LoopContinues(exprValue,labelSet) is false, then return exprValue.
   b. Assert: keys.[[type]] is continue.
   c. Return Completion({[[type]]: break, [[value]]: empty, [[target]]: empty}).
8. Return keys.

Runtime Semantics: For In/Of Body Evaluation Abstract Operation

The abstract operation For In/Of Body Evaluation is called with arguments lhs, stmt, keys, lhsKind, and labelSet. The value of lhsKind is either assignment, varBinding or lexicalBinding.

1. Let oldEnv be the running execution context’s LexicalEnvironment.
2. Let V be undefined.
3. Repeat
   a. Let nextResult be the result of IteratorNext(keys).
   b. ReturnIfAbrupt(nextResult).
   c. Let done be IteratorComplete(nextResult).
   d. ReturnIfAbrupt(done).
   e. If done is true, then return NormalCompletion(V).
   f. Let nextValue be the result of IteratorValue(nextResult).
   g. ReturnIfAbrupt(nextValue).
   h. If lhsKind is assignment, then
      i. Assert: lhs is a LeftHandSideExpression.
      ii. If lhs is neither an ObjectLiteral nor an ArrayLiteral then
         1. Let lhsRef be the result of evaluating lhs (it may be evaluated repeatedly).
         2. Let status be the result of performing PutValue(lhsRef, nextValue).
      iii. Else
         1. Let AssignmentPattern be the parse of the source code corresponding to lhs using AssignmentPattern as the goal symbol.
         2. Let rval be ToObject(nextValue).
         3. If rval is an abrupt completion, then let status be rval.
         4. Else, let status be the result of performing Destructuring Assignment Evaluation of AssignmentPattern using rval as the argument.
      i. Else if lhsKind is varBinding, then
         i. Assert: lhs is a ForBinding.
         ii. Let status be the result of performing Binding Initialisation for lhs passing nextValue and undefined as the arguments.
      j. Else,
13.7 The `continue` Statement

**Syntax**

```
ContinueStatement : continue ; continue [no LineTerminator here] Identifier ;
```

**13.7.1 Static Semantics**

**Static Semantics: Early Errors**

```
ContinueStatement : continue ;
```

- It is a Syntax Error if this production is not nested, directly or indirectly (but not crossing function boundaries), within an `IterationStatement`.

```
ContinueStatement : continue [no LineTerminator here] Identifier ;
```

- It is a Syntax Error if `Identifier` does not appear in the `CurrentLabelSet` of an enclosing (but not crossing function boundaries) `IterationStatement`.

**13.7.2 Runtime Semantics**

**Runtime Semantics: Evaluation**

```
ContinueStatement : continue ;
```

1. Return Completion `[[type]]: continue, [[value]]: empty, [[target]]: empty`.

```
ContinueStatement : continue [no LineTerminator here] Identifier ;
```

1. Return Completion `[[type]]: continue, [[value]]: empty, [[target]]: Identifier`.

13.8 The `break` Statement

**Syntax**

```
BreakStatement : break ; break [no LineTerminator here] Identifier ;
```

**13.8.1 Static Semantics**

**Static Semantics: Early Errors**
BreakStatement:  break  ;

• It is a Syntax Error if this production is not nested, directly or indirectly (but not crossing function boundaries), within an IterationStatement or a SwitchStatement.

BreakStatement:  break  [no LineTerminator here] Identifier  ;

• It is a Syntax Error if Identifier does not appear in the CurrentLabelSet of an enclosing (but not crossing function boundaries) Statement.

13.8.2 Runtime Semantics

Runtime Semantics: Evaluation

BreakStatement:  break  ;
1. Return Completion {[[type]]: break, [[value]]: empty, [[target]]: empty}.

BreakStatement:  break  [no LineTerminator here] Identifier  ;
1. Return Completion {[[type]]: break, [[value]]: empty, [[target]]: Identifier}.

13.9 The return Statement

Syntax

ReturnStatement:  return  ;
   return  [no LineTerminator here] Expression  ;

NOTE A return statement causes a function to cease execution and return a value to the caller. If Expression is omitted, the return value is undefined. Otherwise, the return value is the value of Expression.

13.9.1 Static Semantics

Static Semantics: Early Errors

• It is a Syntax Error if a return statement is not within a FunctionBody or a GeneratorBody.

13.9.2 Runtime Semantics

Runtime Semantics: Evaluation

ReturnStatement:  return  ;
1. Return Completion {[[type]]: return, [[value]]: undefined, [[target]]: empty}.

1. Let exprRef be the result of evaluating Expression.
2. Let exprValue be GetValue(exprRef).
3. ReturnIfAbrupt(exprValue).
4. Return Completion {[[type]]: return, [[value]]: exprValue, [[target]]: empty}.

13.10 The with Statement

Syntax

WithStatement:  with  { Expression  } Statement
NOTE The `with` statement adds an object environment record for a computed object to the lexical environment of the running execution context. It then executes a statement using this augmented lexical environment. Finally, it restores the original lexical environment.

### 13.10.1 Static Semantics

#### Static Semantics: Early Errors

**WithStatement**: `with { Expression } Statement`

- It is a Syntax Error if the code that matches this production is contained in strict code.

#### Static Semantics: VarDeclaredNames

**WithStatement**: `with { Expression } Statement`

1. Return the VarDeclaredNames of `Statement`.

### 13.10.2 Runtime Semantics

#### Runtime Semantics: Evaluation

**WithStatement**: `with { Expression } Statement`

1. Let `val` be the result of evaluating `Expression`.
2. Let `obj` be `ToObject(GetValue(val))`.
3. ReturnIfAbrupt(`obj`).
4. Let `oldEnv` be the running execution context’s LexicalEnvironment.
5. Let `newEnv` be the result of calling `NewObjectEnvironment` passing `obj` and `oldEnv` as the arguments.
6. Set the `withEnvironment` flag of `newEnv`’s environment record to `true`.
7. Let `blackListArray` be the result of `Get(obj, @@unscopables)`.
8. ReturnIfAbrupt(`blackListArray`).
9. If `Type(blackListArray)` is Object, then
   a. Let `blacklist` be `CreateListFromArray(blackListArray)`.  
   b. ReturnIfAbrupt(`blackListArray`).
   c. Set `withEnvironment` of `newEnv`’s environment record to `blackListArray`.
10. Set the running execution context’s LexicalEnvironment to `newEnv`.
11. Let `C` be the result of evaluating `Statement`.
12. Set the running execution context’s LexicalEnvironment to `oldEnv`.
13. Return `C`.

NOTE No matter how control leaves the embedded `Statement`, whether normally or by some form of abrupt completion or exception, the LexicalEnvironment is always restored to its former state.

### 13.11 The `switch` Statement

#### Syntax

**SwitchStatement**: `switch { Expression } CaseBlock`

**CaseBlock**: `{ CaseClauses_opt } CaseClauses CaseClauses_opt`

**CaseClauses**: `{ CaseClause CaseClauses }`
CaseClause:
  case Expression : StatementListopt

DefaultClause:
  default : StatementListopt

13.11.1 Static Semantics

Static Semantics: Early Errors

CaseBlock : [ CaseClauses ]

• It is a Syntax Error if the LexicallyDeclaredNames of CaseClauses contains any duplicate entries.
• It is a Syntax Error if any element of the LexicallyDeclaredNames of CaseClauses also occurs in the VarDeclaredNames of CaseClauses.

Static Semantics: LexicalDeclarations

CaseBlock : [ ]
1. Return a new empty List.

CaseBlock : [ CaseClausesopt DefaultClause CaseClausesopt ]
1. If the first CaseClauses is present, let declarations be the LexicalDeclarations of the first CaseClauses.
2. Else let declarations be a new empty List.
3. Append to declarations the elements of the LexicalDeclarations of the DefaultClause.
4. If the second CaseClauses is not present, return declarations.
5. Else return the result of appending to declarations the elements of the LexicalDeclarations of the second CaseClauses.

CaseClauses : CaseClauses CaseClause
1. Let declarations be LexicalDeclarations of CaseClauses.
2. Append to declarations the elements of the LexicalDeclarations of CaseClause.
3. Return declarations.

CaseClause : case Expression : StatementListopt
1. If the StatementList is present, return the LexicalDeclarations of StatementList.
2. Else return a new empty List.

DefaultClause : default : StatementListopt
1. If the StatementList is present, return the LexicalDeclarations of StatementList.
2. Else return a new empty List.

Static Semantics: LexicallyDeclaredNames

CaseBlock : [ ]
1. Return a new empty List.

CaseBlock : [ CaseClausesopt DefaultClause CaseClausesopt ]
1. If the first CaseClauses is present, let names be the LexicallyDeclaredNames of the first CaseClauses.
2. Else let names be a new empty List.
3. Append to names the elements of the LexicallyDeclaredNames of the DefaultClause.
4. If the second CaseClauses is not present, return names.
5. Else return the result of appending to \textit{names} the elements of the \texttt{LexicallyDeclaredNames} of the second \texttt{CaseClauses}.

\texttt{CaseClauses : CaseClauses CaseClause}

1. Let \textit{names} be \texttt{LexicallyDeclaredNames} of \texttt{CaseClauses}.
2. Append to \textit{names} the elements of the \texttt{LexicallyDeclaredNames} of \texttt{CaseClause}.
3. Return \textit{names}.

\texttt{CaseClause : case } \texttt{Expression : StatementList}

1. If the \texttt{StatementList} is present, return the \texttt{LexicallyDeclaredNames} of \texttt{StatementList}.
2. Else return a new empty List.

\texttt{DefaultClause : default : StatementList}

1. If the \texttt{StatementList} is present, return the \texttt{LexicallyDeclaredNames} of \texttt{StatementList}.
2. Else return a new empty List.

\textbf{Static Semantics: VarDeclaredNames}

\texttt{SwitchStatement : switch ( Expression ) CaseBlock}

1. Return the \texttt{VarDeclaredNames} of \texttt{CaseBlock}.

\texttt{CaseBlock : \{ \}}

1. Return a new empty List.

\texttt{CaseBlock : \{ CaseClauses\opt DefaultCase CaseClauses\opt \}}

1. If the first \texttt{CaseClauses} is present, let \textit{names} be the \texttt{VarDeclaredNames} of the first \texttt{CaseClauses}.
2. Else let \textit{names} be a new empty List.
3. Append to \textit{names} the elements of the \texttt{VarDeclaredNames} of the \texttt{DefaultCase}.
4. If the second \texttt{CaseClauses} is not present, return \textit{names}.
5. Else return the result of appending to \textit{names} the elements of the \texttt{VarDeclaredNames} of the second \texttt{CaseClauses}.

\texttt{CaseClauses : CaseClauses CaseClause}

1. Let \textit{names} be \texttt{VarDeclaredNames} of \texttt{CaseClauses}.
2. Append to \textit{names} the elements of the \texttt{VarDeclaredNames} of \texttt{CaseClause}.
3. Return \textit{names}.

\texttt{CaseClause : case } \texttt{Expression : StatementList}

1. If the \texttt{StatementList} is present, return the \texttt{VarDeclaredNames} of \texttt{StatementList}.
2. Else return a new empty List.

\texttt{DefaultClause : default : StatementList}

1. If the \texttt{StatementList} is present, return the \texttt{VarDeclaredNames} of \texttt{StatementList}.
2. Else return a new empty List.

\textbf{13.11.2 Runtime Semantics}

\textbf{Runtime Semantics: Case Block Evaluation}

With argument \textit{input}.
CaseBlock: { CaseClauses\_opt }

1. Let \( V = \text{undefined} \).
2. Let \( A \) be the list of CaseClause items in source text order.
3. Let searching be true.
4. Repeat, while searching is true
   a. Let \( C \) be the next CaseClause in \( A \). If there is no such CaseClause, return NormalCompletion(\( V \)).
   b. Let clauseSelector be the result of Case Selector Evaluation of \( C \).
   c. ReturnIfAbrupt(clauseSelector).
   d. Let matched be the result of performing Strict Equality Comparison \( \text{input} \equiv \text{clauseSelector} \).
      i. If matched is true, then
         i. Set searching to false.
   e. If matched is true, then
      i. Set searching to false.
         ii. If \( C \) has a StatementList, then
               1. Evaluate \( C \)'s StatementList and let \( V \) be the result.
               2. ReturnIfAbrupt(\( V \)).
5. Repeat
   a. Let \( C \) be the next CaseClause in \( A \). If there is no such CaseClause, return NormalCompletion(\( V \)).
   b. If \( C \) has a StatementList, then
      i. Evaluate \( C \)'s StatementList and let \( R \) be the result.
      ii. If \( R \) is not empty, then let \( V = R \).
      iii. If \( R \) is an abrupt completion, then return Completion {[[type]]: \( R \), [[value]]: \( V \), [[target]]: \( R \).[target]]).
6. Let foundInB be false.
7. If foundInB is false, then
   a. Let \( B \) be a new list containing the CaseClause items in the second CaseClauses, in source text order.
   b. Repeat, letting \( C \) be in order each CaseClause in \( B \)
      i. If foundInB is false, then
         i. Let clauseSelector be the result of Case Selector Evaluation of \( C \).
         ii. If clauseSelector is an abrupt completion, then
            1. If clauseSelector.[[value]] is empty, then return Completion {[[type]]: clauseSelector.[[type]], [[value]]: undefined, [[target]]: clauseSelector.[[target]])
            2. Else, return clauseSelector.
   c. Let foundInB be the result of performing Strict Equality Comparison \( \text{input} \equiv \text{clauseSelector} \).
   d. If foundInB is true, then
      i. Evaluate CaseClause C and let \( R \) be the result.
      ii. If \( R \) is not empty, then let \( V = R \).
      iii. If \( R \) is an abrupt completion, then return Completion {[[type]]: \( R \), [[value]]: \( V \), [[target]]: \( R \).[target]]).
   e. If foundInB is true, then return NormalCompletion(\( V \)).
8. Evaluate DefaultClause and let $R$ be the result.
9. If $R.[\text{value}]$ is not empty, then let $V = R.[\text{value}]$.
10. If $R$ is an abrupt completion, then return Completion
    \begin{verbatim}
      {(\{type\}: R.[\text{type}], \{value\}: V, \{target\}: R.[\text{target}])}
    \end{verbatim}
11. Let $B$ be a new List containing the CaseClause items in the second CaseClauses, in source text order.
12. Repeat, letting $C$ be in order each CaseClause in $B$ (NOTE: this is another complete iteration of the second CaseClauses)
    a. Evaluate CaseClause $C$ and let $R$ be the result
    b. If $R.[\text{value}]$ is not empty, then let $V = R.[\text{value}]$.
    c. If $R$ is an abrupt completion, then return Completion
       \begin{verbatim}
         {(\{type\}: R.[\text{type}], \{value\}: V, \{target\}: R.[\text{target}])}
       \end{verbatim}
13. Return NormalCompletion($V$).

**Runtime Semantics: Case Selector Evaluation**

*CaseClause: case Expression : StatementList*  
1. Let $exprRef$ be the result of evaluating $Expression$.
2. Return GetValue($exprRef$).

**NOTE** Case Selector Evaluation does not execute the associated StatementList. It simply evaluates the $Expression$ and returns the value, which the CaseBlock algorithm uses to determine which StatementList to start executing.

**Runtime Semantics: Evaluation**

*SwitchStatement: switch ( Expression ) CaseBlock*
1. Let $exprRef$ be the result of evaluating $Expression$.
2. Let $switchValue$ be $GetValue(exprRef)$.
3. ReturnIfAbrupt($switchValue$).
4. Let $oldEnv$ be the running execution context’s LexicalEnvironment.
5. Let $blockEnv$ be the result of calling NewDeclarativeEnvironment passing $oldEnv$ as the argument.
6. Perform Block Declaration Instantiation using CaseBlock and $blockEnv$.
7. Let $R$ be the result of performing Case Block Evaluation of CaseBlock with argument $switchValue$.
8. Set the running execution context’s LexicalEnvironment to $oldEnv$.

**NOTE** No matter how control leaves the SwitchStatement the LexicalEnvironment is always restored to its former state.

*CaseClause: case Expression :*
1. Return NormalCompletion($empty$).

*CaseClause: case Expression : StatementList*
1. Return the result of evaluating StatementList.

*DefaultClause: default :*
1. Return NormalCompletion($empty$).

*DefaultClause: default : StatementList*
1. Return the result of evaluating StatementList.

### 13.12 Labelled Statements

**Syntax**

*LabelledStatement:*

*Identifier : Statement*
NOTE A Statement may be prefixed by a label. Labelled statements are only used in conjunction with labelled break and continue statements. ECMAScript has no goto statement. A Statement can be part of a LabelledStatement, which itself can be part of a LabelledStatement, and so on. The labels introduced this way are collectively referred to as the "current label set" when describing the semantics of individual statements. A LabelledStatement has no semantic meaning other than the introduction of a label to a label set. The label set of an IterationStatement or a SwitchStatement initially contains the single element empty. The label set of any other statement is initially empty.

13.12.1 Static Semantics

Static Semantics: Early Errors

- It is a Syntax Error if a LabelledStatement is enclosed by a LabelledStatement with the same Identifier as the enclosed LabelledStatement. This does not apply to a LabelledStatement appearing within the body of a FunctionDeclaration and a LabelledStatement that encloses, directly or indirectly the FunctionDeclaration.

Static Semantics: VarDeclaredNames

LabelledStatement: Identifier : Statement

1. Return the VarDeclaredNames of Statement.

13.12.2 Runtime Semantics

Runtime Semantics: Labelled Evaluation

With argument labelSet.

LabelledStatement: Identifier : Statement

1. Let label be the StringValue of Identifier.
2. Let newLabelSet be a new List containing label and the elements of labelSet.
3. If Statement is either LabelledStatement or BreakableStatement, then
   a. Let stmtResult be the result of performing Labelled Evaluation of Statement with argument newLabelSet.
4. Else,
   a. Let stmtResult be the result of evaluating Statement.
5. If stmtResult.[[type]] is break and stmtResult.[[target]] is the same value as label, then
   a. Let result be NormalCompletion(stmtResult.[[value]]).
6. Else,
   a. Let result be stmtResult.
7. Return result.

Runtime Semantics: Evaluation

LabelledStatement: Identifier : Statement

1. Let newLabelSet be a new empty List.
2. Return the result of performing Labelled Evaluation of this LabelledStatement with argument newLabelSet.

13.13 The throw Statement

Syntax

Runtime Semantics: Evaluation

The production `ThrowStatement : throw [noLineTerminator here] Expression ;` is evaluated as follows:

1. Let `exprRef` be the result of evaluating `Expression`.
2. Let `exprValue` be `GetValue(exprRef)`.
3. ReturnIfAbrupt(`exprValue`).
4. Return Completion `[[type]]: throw, [[value]]: exprValue, [[target]]: empty`.

13.14 The `try` Statement

Syntax

TryStatement :  
  `try` Block Catch  
  `try` Block Finally  
  `try` Block Catch Finally

Catch :  
  `catch` ( CatchParameter ) Block

Finally :  
  `finally` Block

CatchParameter :  
  BindingIdentifier  
  BindingPattern

NOTE The `try` statement encloses a block of code in which an exceptional condition can occur, such as a runtime error or a `throw` statement. The `catch` clause provides the exception-handling code. When a catch clause catches an exception, its `CatchParameter` is bound to that exception.

13.14.1 Static Semantics

Static Semantics: Early Errors

Catch : `catch` ( CatchParameter ) Block

- It is a Syntax Error if any element of the `BoundNames` of `CatchParameter` also occurs in the `LexicallyDeclaredNames` of `Block`.
- It is a Syntax Error if any element of the `BoundNames` of `CatchParameter` also occurs in the `VarDeclaredNames` of `Block`.

Static Semantics: VarDeclaredNames

TryStatement : `try` Block Catch

1. Let `names` be `VarDeclaredNames` of `Block`.
2. Append to `names` the elements of the `VarDeclaredNames` of `Catch`.
3. Return `names`.

TryStatement : `try` Block Finally

1. Let `names` be `VarDeclaredNames` of `Block`.
2. Append to `names` the elements of the `VarDeclaredNames` of `Finally`.
3. Return `names`.

TryStatement : `try` Block Catch Finally

Commented [AWB95]: Note that this is a new restriction that does not exist in ES5.
1. Let `names` be `VarDeclaredNames of Block`.
2. Append to `names` the elements of the `VarDeclaredNames of Catch`.
3. Append to `names` the elements of the `VarDeclaredNames of Finally`.
4. Return `names`.

**Catch**: `catch (CatchParameter) Block`

1. Return the `VarDeclaredNames of Block`.

### 13.14.2 Runtime Semantics

**Runtime Semantics: Binding Initialisation**

With arguments `value` and `environment`.

*NOTE* `undefined` is passed for `environment` to indicate that a `PutValue` operation should be used to assign the initialisation value. This is the case for `var` statements formal parameter lists of non-strict functions. In those cases a lexical binding is hosted and preinitialised prior to evaluation of its initialiser.

**CatchParameter**: `BindingPattern`

1. Let `exceptionObj` be `ToObject(value)`.
2. ReturnIfAbrupt(`exceptionObj`).
3. Return the result of performing `Binding Initialisation` for `BindingPattern` passing `exceptionObj` and `environment` as the arguments.

**Runtime Semantics: Catch Clause Evaluation**

*with parameter thrownValue*

**Catch**: `catch (CatchParameter) Block`

1. Let `oldEnv` be the running execution context’s `LexicalEnvironment`.
2. Let `catchEnv` be the result of calling `NewDeclarativeEnvironment` passing `oldEnv` as the argument.
3. For each element `argName` of the `BoundNames of CatchParameter`, do
   a. Call the `CreateMutableBinding` concrete method of `catchEnv` passing `argName` as the argument.
   b. Assert: The above call to `CreateMutableBinding` will never return an abrupt completion.
4. Let `status` be the result of performing `Binding Initialisation` for `CatchParameter` passing `thrownValue` and `catchEnv` as arguments.
5. ReturnIfAbrupt(`status`).
6. Set the running execution context’s `LexicalEnvironment` to `catchEnv`.
7. Let `B` be the result of evaluating `Block`.
8. Set the running execution context’s `LexicalEnvironment` to `oldEnv`.

*NOTE* No matter how control leaves the `Block` the `LexicalEnvironment` is always restored to its former state.

**Runtime Semantics: Evaluation**

**TryStatement**: `try Block Catch`

1. Let `B` be the result of evaluating `Block`.
2. If `B[[type]]` is not `throw`, return `B`.
3. Return the result of performing `Catch Clause Evaluation` of `Catch` with parameter `B`[[value]].

**TryStatement**: `try Block Finally`

1. Let `B` be the result of evaluating `Block`.
2. Let `F` be the result of evaluating `Finally`.

Commented [AWB1096]: Catching a thrown null or `undefined` with a destructuring parameter rethrows a `TypeError`. Does this make sense?
3. If `F.[[type]]` is normal, return `B`
4. Return `F`.

**TryStatement:** `try` Block `Catch` `Finally`

1. Let `B` be the result of evaluating `Block`
2. If `B.[[type]]` is throw, then
   a. Let `C` be the result of performing `Catch` Clause Evaluation of `Catch` with parameter `B.value`
3. Else `B.[[type]]` is not throw
   a. Let `C` be `B`
4. Let `F` be the result of evaluating `Finally`
5. If `F.[[type]]` is normal, return `C`
6. Return `F`

### 13.15 The debugger statement

**Syntax**

```
DebuggerStatement:
  debugger ;
```

**Runtime Semantics: Evaluation**

**NOTE** Evaluating the `DebuggerStatement` production may allow an implementation to cause a breakpoint when run under a debugger. If a debugger is not present or active this statement has no observable effect.

The production `DebuggerStatement : debugger ;` is evaluated as follows:

1. If an implementation defined debugging facility is available and enabled, then
   a. Perform an implementation defined debugging action
   b. Let `result` be an implementation defined Completion value
2. Else
   a. Let `result` be `NormalCompletion(empty)`
3. Return `result`.

### 14 ECMAScript Language: Functions and Classes

#### 14.1 Function Definitions

**Syntax**

```
FunctionDeclaration:
  function BindingIdentifier ( FormalParameters ) { FunctionBody }

FunctionExpression:
  function BindingIdentifier opt ( FormalParameters ) { FunctionBody }

StrictFormalParameters:
  FormalParameter

FormalParameters:
  [empty]

FormalParameterList, FunctionRestParameter

FormalParameterList:
  FunctionRestParameter
  FormalsList
  FormalsList, FunctionRestParameter
FormalsList : FormalParameter, FormalsList
FormalParameter : BindingElement

FunctionRestParameter : \... BindingIdentifier

FormalParameter : BindingElement

FunctionBody : FunctionStatementList

FunctionStatementList : StatementList

Supplemental Syntax
The following productions are used as an aid in specifying the semantics of certain ECMAScript language features. They are not used when parsing ECMAScript source code.

FunctionBody : ThrowTypeError

ThrowTypeError : [empty]

14.1.1 Static Semantics

Static Semantics: Early Errors

FunctionDeclaration : function BindingIdentifier ( FormalParameters ) { FunctionBody } and
FunctionExpression : function BindingIdentifieropt ( FormalParameters ) { FunctionBody }

- It is a Syntax Error if FunctionBody Contains YieldExpression is true.
- If the source code matching this production is strict code, the Early Error rules for StrictFormalParameters are applied.
- It is a Syntax Error if IsSimpleParameterList of FormalParameters is false and any element of the BoundNames of FormalParameters also occurs in the VarDeclaredNames of FunctionBody.
- It is a Syntax Error if any element of the BoundNames of FormalParameters also occurs in the LexicallyDeclaredNames of FunctionBody.

NOTE: The LexicallyDeclaredNames of a FunctionBody does not include identifiers bound using var or function declarations. Simple parameter lists bind identifiers as VarDeclaredNames. Parameter lists that contain destructuring patterns, default value initialisers, or a rest parameter bind identifiers as LexicallyDeclaredNames.

StrictFormalParameters:

- It is a Syntax Error if BoundNames of FormalParameters contains any duplicate elements.
- It is a Syntax Error if BoundNames of FormalParameters contains either "eval" or "arguments".

FormalParameters : FormalParameterList

- It is a Syntax Error if FormalParameters Contains YieldExpression is true.
- It is a Syntax Error if IsSimpleParameterList of FormalParameterList is false and BoundNames of FormalParameterList contains any duplicate elements.
- It is a Syntax Error if IsSimpleParameterList of FormalParameterList is false and BoundNames of FormalParameterList contains either "eval" or "arguments".
It is a Syntax Error if the source code matching this production is strict code and BoundNames of FormalParameterList contains any duplicate elements.

NOTE Multiple occurrences of the same Identifier in a FormalParameterList is only allowed for non-strict functions and generator functions that have simple parameter lists.

FunctionStatementList : StatementList

• It is a Syntax Error if the LexicallyDeclaredNames of StatementList contains any duplicate entries.
• It is a Syntax Error if any element of the LexicallyDeclaredNames of StatementList also occurs in the VarDeclaredNames of StatementList.

FormalParameter : BindingElement

• It is a Syntax Error if BindingElement Contains YieldExpression.

Static Semantics: BoundNames

FunctionDeclaration : function BindingIdentifier ( FormalParameters ) { FunctionBody }
1. Return the BoundNames of BindingIdentifier.

FormalParameters : [empty]
1. Return an empty List.

FormalParameterList : FormalsList , FunctionRestParameter
1. Let names be BoundNames of FormalsList.
2. Append to names the BoundNames of FunctionRestParameter.
3. Return names.

FormalsList : FormalsList , FormalParameter
1. Let names be BoundNames of FormalsList.
2. Append to names the elements of BoundNames of FormalParameter.
3. Return names.

Static Semantics: Contains

With parameter symbol.

FunctionDeclaration : function BindingIdentifier ( FormalParameters ) { FunctionBody }
1. Return false.

FunctionExpression : function BindingIdentifier opt ( FormalParameters ) { FunctionBody }
1. Return false.

NOTE Static semantic rules that depend upon substructure generally do not look into function definitions.

Static Semantics: ExpectedArgumentCount

FormalParameters : [empty]
1. Return 0.
FormalParameterList : FunctionRestParameter
  1. Return 0.

FormalParameterList : FormalsList , FunctionRestParameter
  1. Return the ExpectedArgumentCount of FormalsList.

**NOTE** The *ExpectedArgumentCount of a FormalParameterList* is the number of FormalParameters to the left of either the rest parameter or the first FormalParameter with an Initialiser. A FormalParameter without an initialiser is allowed after the first parameter with an initialiser but such parameters are considered to be optional with undefined as their default value.

FormalsList : FormalParameter
  1. If HasInitialiser of FormalParameter is false return 0
  2. Return 1.

FormalsList : FormalsList , FormalParameter
  1. Let count be the ExpectedArgumentCount of FormalsList
  2. If HasInitialiser of FormalsList is true or HasInitialiser of FormalParameter is true, then return count.

**Static Semantics: HasInitialiser**

FormalsList : FormalsList , FormalParameter
  1. If HasInitialiser of FormalsList is true, then return true.
  2. Return HasInitialiser of FormalParameter.

**Static Semantics: IsSimpleParameterList**

FunctionDeclaration : function BindingIdentifier ( FormalParameters ) { FunctionBody }
  1. Return false.

**Static Semantics: IsSimpleParameterList**

FormalParameters : [empty]
  1. Return true.

FormalParameterList : FunctionRestParameter
  1. Return false.

FormalParameterList : FormalsList , FunctionRestParameter
  1. Return false.

FormalsList : FormalsList , FormalParameter
  1. If IsSimpleParameterList of FormalsList is false, return false.

FormalParameter : BindingElement
  1. If HasInitialiser of BindingElement is true, return false.
  2. If FormalParameter Contains BindingPattern is true, return false.
3. Return `true`.

**Static Semantics: IsStrict**

`FunctionStatementList : StatementListopt`

1. If this `FunctionStatementList` is contained in strict code or if `StatementList` is strict code, then return `true`. Otherwise, return `false`.

**Static Semantics: LexicallyDeclaredNames**

`FunctionDeclaration : function BindingIdentifier ( FormalParameters ) { FunctionBody }`

1. Return the BoundNames of `BindingIdentifier`.

`FunctionStatementList : [empty]`

1. Return an empty List.

`FunctionStatementList : StatementList`

1. Return `TopLevelLexicallyDeclaredNames` of `StatementList`.

**Static Semantics: VarDeclaredNames**

`FunctionDeclaration : function BindingIdentifier ( FormalParameters ) { FunctionBody }`

1. Return an empty List.

`FunctionBody : [empty]`

1. Return an empty List.

`FunctionBody : StatementList`

1. Return `TopLevelVarDeclaredNames` of `StatementList`.

**14.1.1.2 Runtime Semantics**

**Runtime Semantics: Binding Initialisation**

With parameters `value` and `environment`.

NOTE When `undefined` is passed for `environment` it indicates that a `PutValue` operation should be used to assign the initialisation value. This is the case for formal parameter lists of non-strict functions. In that case the formal parameter bindings are preinitialised in order to deal with the possibility of multiple parameters with the same name.

`FormalParameters : [empty]`

1. Return `NormalCompletion(empty)`.

`FormalParameterList : FunctionRestParameter`

1. Return the result of performing Indexed Binding Initialisation for `FunctionRestParameter` using `value`, `0`, and `environment` as the arguments.
FormalParameterList : FormalsList

1. Return the result of performing Indexed Binding Initialisation for FormalsList using value, 0, and environment as the arguments.

FormalParameterList : FormalsList, FunctionRestParameter

1. Let restIndex be the result of performing Indexed Binding Initialisation for FormalsList using value, 0, and environment as the arguments.
2. ReturnIfAbrupt(restIndex).
3. Return the result of performing Indexed Binding Initialisation for FunctionRestParameter using value, restIndex, and environment as the arguments.

Runtime Semantics: EvaluateBody

With parameter functionObject.

FunctionBody : FunctionStatementListopt

1. The code of this FunctionBody is strict mode code if it is contained in strict mode code or if the Directive Prologue (15.2) of its FunctionStatementList contains a Use Strict Directive or if any of the conditions in 10.1.1 apply. If the code of this FunctionBody is strict mode code, FunctionStatementList is evaluated in the following steps as strict mode code. Otherwise, StatementList is evaluated in the following steps as non-strict mode code.
2. If FunctionStatementList is not present, then return NormalCompletion undefined).
3. Let result be the result of evaluating FunctionStatementList.
4. If result.[[type]] is return then return NormalCompletion(result.[[value]]).
5. ReturnIfAbrupt(result).
6. Return NormalCompletion(undefined).

FunctionBody : ThrowTypeError

1. Throw a TypeError exception.

Runtime Semantics: Indexed Binding Initialisation

With parameters array, nextIndex, and environment.

FormalList : FormalParameter

1. Let status be the result of performing Indexed Binding Initialisation for FormalParameter using array, nextIndex, and environment as the arguments.
2. ReturnIfAbrupt(status).
3. Return nextIndex + 1.

FormalList : FormalList, FormalParameter

1. Let lastIndex be the result of performing Indexed Binding Initialisation for FormalsList using array, nextIndex, and environment as the arguments.
2. ReturnIfAbrupt(lastIndex).
3. Let status be the result of performing Indexed Binding Initialisation for FormalParameter using array, lastIndex, and environment as the arguments.
4. ReturnIfAbrupt(status).
5. Return lastIndex + 1.

FunctionRestParameter : ... BindingIdentifier

1. Assert: array is a well formed arguments object and hence it has a valid integer valued "length" property.
2. Let status be the result of Get(array, "length").
3. Let argumentsLength be status.[value].
4. Let A be the result of the abstract operation ArrayCreate with argument 0.
5. Let n=0;
6. Repeat, while nextIndex < argumentsLength
   a. Let P be ToString(nextIndex).
   b. Assert: array is a well formed arguments object, hence it must have a property P.
   c. Let v be the result of Get(array, P).
   d. Call the [[DefineOwnProperty]] internal method of A with arguments ToString(n) and Property Descriptor {
      [[Value]]: v, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}.  
   e. Let n = n+1.
   f. Let nextIndex = nextIndex +1.
7. Return the result of performing Binding Initialisation for BindingIdentifier using A and environment as arguments.

Runtime Semantics: InstantiateFunctionObject
With parameter scope.
FunctionDeclaration : function BindingIdentifier { FormalParameters } { FunctionBody }
1. If the FunctionDeclaration is contained in strict code or if its FunctionBody is strict code, then let strict be true.  
   Otherwise let strict be false.
2. Let F be the result of performing the FunctionCreate abstract operation with arguments Normal, FormalParameters, FunctionBody, scope, and strict.
3. Perform the abstract operation MakeConstructor with argument F.
4. Return F.

Runtime Semantics: Evaluation
FunctionDeclaration : function BindingIdentifier { FormalParameters } { FunctionBody }
1. Return NormalCompletion(empty)
FunctionExpression : function ( FormalParameters ) { FunctionBody }
1. If the FunctionExpression is contained in strict code or if its FunctionBody is strict code, then let strict be true.  
   Otherwise let strict be false.
2. Let scope be the LexicalEnvironment of the running execution context.
3. Let closure be the result of performing the FunctionCreate abstract operation with arguments Normal, FormalParameters, FunctionBody, scope, and strict.
4. Perform the abstract operation MakeConstructor with argument closure.
5. Return closure.
FunctionExpression : function BindingIdentifier { FormalParameters } { FunctionBody }
1. If the FunctionExpression is contained in strict code or if its FunctionBody is strict code, then let strict be true.  
   Otherwise let strict be false.
2. Let funcEnv be the result of calling NewDeclarativeEnvironment passing the running execution context’s Lexical Environment as the argument
3. Let envRec be funcEnv’s environment record.
4. Let name be StringValue of BindingIdentifier.
5. Call the CreateImmutableBinding concrete method of envRec passing name as the argument.
6. Let closure be the result of performing the FunctionCreate abstract operation with arguments Normal, FormalParameters, FunctionBody, funcEnv, and strict.
7. Perform the abstract operation MakeConstructor with argument closure.
8. Call the InitialiseBinding concrete method of envRec passing name and closure as the arguments.
9. Return NormalCompletion(closure).
NOTE 1 The BindingIdentifier in a FunctionExpression can be referenced from inside the FunctionExpression's FunctionBody to allow the function to call itself recursively. However, unlike in a FunctionDeclaration, the BindingIdentifier in a FunctionExpression cannot be referenced from and does not affect the scope enclosing the FunctionExpression.

NOTE 2 A prototype property is automatically created for every function defined using a FunctionDeclaration or FunctionExpression, to allow for the possibility that the function will be used as a constructor.

14.2 Arrow Function Definitions

Syntax

ArrowFunction : ArrowParameters => ConciseBody

ArrowParameters : BindingIdentifier CoverParenthesisedExpressionAndArrowParameterList

ConciseBody : [lookahead == { ] AssignmentExpression { FunctionBody ]

Supplemental Syntax

When processing the production ArrowParameters : CoverParenthesisedExpressionAndArrowParameterList the following grammar is used to refine the interpretation of CoverParenthesisedExpressionAndArrowParameterList.

ArrowFormalParameters : ( StrictFormalParameters )

14.2.1 Static Semantics

14.2.1.1 Static Semantics: Early Errors

ArrowFunction : ArrowParameters => ConciseBody

- It is a Syntax Error if any element of the BoundNames of ArrowParameters also occurs in the VarDeclaredNames of ConciseBody.
- It is a Syntax Error if any element of the BoundNames of ArrowParameters also occurs in the LexicallyDeclaredNames of ConciseBody.

ArrowParameters : BindingIdentifier

- It is a Syntax Error if the StringValue of the sole element of the BoundNames of BindingIdentifier is eval or arguments.

ArrowParameters : CoverParenthesisedExpressionAndArrowParameterList

- It is a Syntax Error if the lexical token sequence matched by CoverParenthesisedExpressionAndArrowParameterList cannot be parsed with no tokens left over using ArrowFormalParameters as the goal symbol.
- It is a Syntax Error if any early errors are present for CoveredFormalsList of CoverParenthesisedExpressionAndArrowParameterList.

ConciseBody : [lookahead == { ] AssignmentExpression

- It is a Syntax Error if AssignmentExpression Contains YieldExpression.
Static Semantics: BoundNames

ArrowParameters : CoverParenthesizedExpressionAndArrowParameterList

1. Let formals be CoveredFormalsList of CoverParenthesizedExpressionAndArrowParameterList.
2. Return the BoundNames of formals.

Static Semantics: Contains

With parameter symbol.

ArrowFunction : ArrowParameters => ConciseBody

1. If symbol is neither super or this, then return false.
2. If ArrowParameters Contains symbol is true, return true;
3. Return ConciseBody Contains symbol.

NOTE Normally, Contains does not look inside most function forms. However, Contains is used to detect this and super usage within an ArrowFunction.

ArrowParameters : CoverParenthesizedExpressionAndArrowParameterList

1. Let formals be CoveredFormalsList of CoverParenthesizedExpressionAndArrowParameterList.
2. Return formals Contains symbol.

Static Semantics: CoveredFormalsList

ArrowParameters : BindingIdentifier

1. Return BindingIdentifier.

CoverParenthesizedExpressionAndArrowParameterList :
  ( Expression )
  ( . . . Identifier )
  ( Expression , . . . Identifier )

1. Return the result of parsing the lexical token stream matched by CoverParenthesizedExpressionAndArrowParameterList using ArrowFormalParameters as the goal symbol.

Static Semantics: ExpectedArgumentCount

ArrowParameters : BindingIdentifier

1. Return 1.

ArrowParameters : CoverParenthesizedExpressionAndArrowParameterList

1. Let formals be CoveredFormalsList of CoverParenthesizedExpressionAndArrowParameterList.
2. Return the ExpectedArgumentCount of formals.

Static Semantics: IsSimpleParameterList

ArrowParameters : BindingIdentifier

1. Return true.

ArrowParameters : CoverParenthesizedExpressionAndArrowParameterList

1. Let formals be CoveredFormalsList of CoverParenthesizedExpressionAndArrowParameterList.
2. Return the IsSimpleParameterList of formals.

**Static Semantics:** LexicallyDeclaredNames

**ConciseBody:** `lookahead e { } AssignmentExpression`

1. Return an empty List.

### 14.2.1.2 Runtime Semantics

**Runtime Semantics:** ConciseBody

1. [lookahead ε { } AssignmentExpression]

### 14.2.1.2 Runtime Semantics

**Runtime Semantics:** Binding Initialisation

With parameters `value` and `environment`

**NOTE** When `undefined` is passed for `environment` it indicates that a `PutValue` operation should be used to assign the initialisation value. This is the case for formal parameter lists of non-strict functions. In this case the formal parameter bindings are preinitialised in order to deal with the possibility of multiple parameters with the same name.

**ArrowParameters:** BindingIdentifier

1. Return the result of performing Binding Initialisation for `BindingIdentifier` using `value` and `environment` as the arguments.

**ArrowParameters:** CoverParenthesisedExpressionAndArrowParameterList

1. Let `formals` be `CoveredFormalsList of CoverParenthesisedExpressionAndArrowParameterList`
2. Return the result of performing Binding Initialisation of `formals` with arguments `value` and `environment`.

**Runtime Semantics:** EvaluateBody

**With parameter functionObject**

**ConciseBody:** `lookahead e { } AssignmentExpression`

1. The code of this `ConciseBody` is strict mode code if it is contained in strict mode code or if any of the conditions in 10.1.1 apply. If the code of this `ConciseBody` is strict mode code, `AssignmentExpression` is evaluated in the following steps as strict mode code. Otherwise, `AssignmentExpression` is evaluated in the following steps as non-strict mode code.
2. Let `exprRef` be the result of evaluating `AssignmentExpression`.
3. Let `exprValue` be `GetValue(exprRef)`.
4. If `exprValue.[[type]]` is a return then return `NormalCompletion(exprValue.[[value]])`.
5. ReturnIfAbrupt(exprValue).
6. Return `NormalCompletion(exprValue)`.

**NOTE** In the absence of extensions to this specification, the test in step 4 will never be true.

**Runtime Semantics:** Evaluation

**ArrowFunction:** ArrowParameters => ConciseBody

1. [lookahead ε { } AssignmentExpression]
2. Let `scope` be the LexicalEnvironment of the running execution context.
3. Let `parameters` be `CoveredFormalsList of ArrowParameters`.
4. Let `closure` be the result of performing the FunctionCreate abstract operation with arguments `Arrow`, `parameters`, `ConciseBody`, `scope`, and `strict`.
5. Return `closure`.

**NOTE** Even though an `ArrowFunction` may contain references to `super`, the FunctionCreate call in step 3 is not passed the optional `homeObject` and `methodName` parameters. An `ArrowFunction` that references `super` is always contained in the scope of a `class` body.

---

*Commented [AWB798]: TODO, need to resolve whether or not ArrowBodies are always strict*

*Commented [AWB999]: TODO If exprRef is a Reference that invokes a getter we probably should find a way to specify that the get call is handled as a tail call*

*Commented [AWB7100]: Confirm: concise methods are always strict code.*
within a non-ArrowFunction and the necessary state to implement `super` is accessible via the `scope` that is captured by the function object of the ArrowFunction.

14.3 Method Definitions

Syntax

MethodDefinition : PropertyName ( StrictFormalParameters ) { FunctionBody }  
GeneratorMethod  
get PropertyName () { FunctionBody }  
set PropertyName ( PropertySetParameterList ) { FunctionBody } 

PropertySetParameterList : BindingIdentifier BindingPattern

NOTE: The single element of a PropertySetParameterList may not have a default value `initializer` because set accessor are always called with an implicitly provided argument.

14.3.1.1 Static Semantics

Static Semantics: Early Errors

MethodDefinition : PropertyName ( StrictFormalParameters ) { FunctionBody }  
• It is a Syntax Error if any element of the BoundNames of StrictFormalParameters also occurs in the VarDeclaredNames of FunctionBody.
• It is a Syntax Error if any element of the BoundNames of StrictFormalParameters also occurs in the LexicallyDeclaredNames of FunctionBody.

MethodDefinition : set PropertyName ( PropertySetParameterList ) { FunctionBody } 
• It is a Syntax Error if IsSimpleParameterList of PropertySetParameterList is false and any element of the BoundNames of PropertySetParameterList also occurs in the VarDeclaredNames of FunctionBody.
• It is a Syntax Error if IsSimpleParameterList of PropertySetParameterList is false and BoundNames of PropertySetParameterList contains any duplicate elements.
• It is a Syntax Error if IsSimpleParameterList of PropertySetParameterList is false and BoundNames of PropertySetParameterList contains either "eval" or "arguments".
• It is a Syntax Error ifBoundNames of PropertySetParameterList contains any duplicate elements.
• It is a Syntax Error if any element of the BoundNames of PropertySetParameterList also occurs in the LexicallyDeclaredNames of FunctionBody.
• It is a Syntax Error if PropertySetParameterList Contains YieldExpression.

Static Semantics: ExpectedArgumentCount

PropertySetParameterList : BindingIdentifier 
1. Return 1.

PropertySetParameterList : BindingPattern
1. Return 1.

Static Semantics: IsSimpleParameterList

PropertySetParameterList : BindingIdentifier
1. Return true.
1. Return false.

**Static Semantics: PropName**

**MethodDefinition** :

\[
\text{PropName ( FormalParameters ) ( FunctionBody )}
\]

\[
\text{get PropName ( ) ( FunctionBody )}
\]

\[
\text{set PropName ( PropertySetParameterList ) ( FunctionBody )}
\]

1. Return PropName of PropertyName.

**Static Semantics: ReferencesSuper**

**MethodDefinition** :

\[
\text{PropertyName ( FormalParameters ) ( FunctionBody )}
\]

1. If FormalParameters Contains **super** is true, then return **true**.
2. Return FunctionBody Contains **super**.

**MethodDefinition** :

\[
\text{get PropertyName ( ) ( FunctionBody )}
\]

1. Return FunctionBody Contains **super**.

**MethodDefinition** :

\[
\text{set PropertyName ( PropertySetParameterList ) ( FunctionBody )}
\]

1. If PropertySetParameterList Contains **super** is true, then return **true**.
2. Return FunctionBody Contains **super**.

**Static Semantics: SpecialMethod**

**MethodDefinition** :

\[
\text{PropertyName ( StrictFormalParameters ) ( FunctionBody )}
\]

1. Return false.

**MethodDefinition** :

\[
\text{GeneratorMethod}
\]

\[
\text{get PropertyName ( ) ( FunctionBody )}
\]

\[
\text{set PropertyName ( PropertySetParameterList ) ( FunctionBody )}
\]

1. Return **true**.

### 14.3.1.2 Runtime Semantics

**Runtime Semantics: Property Definition Evaluation**

With parameter object and optional parameter functionPrototype.

**MethodDefinition** :

\[
\text{PropertyName ( StrictFormalParameters ) ( FunctionBody )}
\]

1. Let propKey be the result of evaluating PropertyName.
2. ReturnIfAbrupt(propKey).
3. Let strict be IsStrict of FunctionBody.
4. Let scope be the running execution context’s LexicalEnvironment.
5. If isComputedPropertyName(propKey) is true, then
   a. Let duplicateKey be the result of calling the [[HasOwnProperty]] internal method of object with argument propKey.
   b. ReturnIfAbrupt(duplicateKey).
   c. If duplicateKey is true, then throw a TypeError exception.
6. If ReferencesSuper of MethodDefinition is true, then
   a. Let closure be the result of performing the FunctionCreate abstract operation with arguments Method, StrictFormalParameters, FunctionBody, scope, and strict and with object as the homeObject optional argument and propKey as the methodName optional argument. If functionPrototype was passed as a parameter then also pass its value as the functionPrototype optional argument of FunctionCreate.

7. Else
   a. Let closure be the result of performing the FunctionCreate abstract operation with arguments Method, StrictFormalParameters, FunctionBody, scope, and strict. If functionPrototype was passed as a parameter then also pass its value as the functionPrototype optional argument of FunctionCreate.

8. Let desc be the Property Descriptor {[[Value]]: closure, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}.

9. Let status be the result of DefinePropertyOrThrow(object, propKey, desc).

10. ReturnIfAbrupt(status).

11. NormalCompletion(closure).

MethodDefinition : GenerateMethod

See 14.4.

MethodDefinition : get PropertyName ( ) ( FunctionBody )

1. Let propKey be the result of evaluating PropertyName.

2. ReturnIfAbrupt(propKey).

3. Let strict be IsStrict of FunctionBody.

4. Let scope be the running execution context’s LexicalEnvironment.

5. Let formalParameterList be the production FormalParameters : [empty].

6. If isComputedPropertyName(propKey) is true, then
   a. Let duplicateKey be the result of calling the [[HasOwnProperty]] internal method of object with argument propKey.
   b. ReturnIfAbrupt(duplicateKey).
   c. If duplicateKey is true, then throw a TypeError exception.

7. Else
   a. Let closure be the result of performing the FunctionCreate abstract operation with arguments Method, formalParameterList, FunctionBody, scope, and strict and with object as the homeObject optional argument and propKey as the methodName optional argument.

8. Else
   a. Let closure be the result of performing the FunctionCreate abstract operation with arguments Method, formalParameterList, FunctionBody, scope, and strict.

9. Let desc be the Property Descriptor {[[Get]]: closure, [[Enumerable]]: true, [[Configurable]]: true}.

10. Let status be the result of DefinePropertyOrThrow(object, propKey, desc).

11. ReturnIfAbrupt(status).

12. Return NormalCompletion(closure).

MethodDefinition : set PropertyName ( PropertySetParameterList ) ( FunctionBody )

1. Let propKey be the result of evaluating PropertyName.

2. ReturnIfAbrupt(propKey).

3. Let strict be IsStrict of FunctionBody.

4. Let scope be the running execution context’s LexicalEnvironment.

5. If isComputedPropertyName(propKey) is true, then
   a. Let duplicateKey be the result of calling the [[HasOwnProperty]] internal method of object with argument propKey.
   b. ReturnIfAbrupt(duplicateKey).
   c. If duplicateKey is true, then throw a TypeError exception.

6. If ReferencesSuper of MethodDefinition is true, then
   a. Let closure be the result of performing the FunctionCreate abstract operation with arguments Method, PropertySetParameterList, FunctionBody, scope, and strict and with object as the homeObject optional argument and propKey as the methodName optional argument.

7. Else
a. Let closure be the result of performing the FunctionCreate abstract operation with arguments Method, PropertySetParameterList, FunctionBody, scope, and strict.

8. Let desc be the Property Descriptor \{[[Set]]: closure, [[Enumerable]]: true, [[Configurable]]: true\}

9. Let status be the result of DefinePropertyOrThrow(object, propKey, desc).

10. ReturnIfAbrupt(status).

11. Return NormalCompletion(closure).

14.4 Generator Function Definitions

Syntax

GeneratorMethod:
  * PropertyName (StrictFormalParameters) { FunctionBody }

GeneratorDeclaration:
  function * BindingIdentifier (FormalParameters) { FunctionBody }

GeneratorExpression:
  function * BindingIdentifierOpt (FormalParameters) { FunctionBody }

YieldExpression:
  yield YieldDelegatorOpt [lexical goal InputElementRegExp AssignmentExpression]

YieldDelegator:
  *

Supplemental Syntax

The following productions are used as an aid in specifying the semantics of certain ECMAScript language features. They are not used when parsing ECMAScript source code.

GeneratorBody:
  FunctionBody Comprehension

14.4.1.1 Static Semantics

Static Semantics: Early Errors

GeneratorMethod:* PropertyName (StrictFormalParameters) { FunctionBody }

• It is a Syntax Error if any element of the BoundNames of StrictFormalParameters also occurs in the VarDeclaredNames of FunctionBody.

• It is a Syntax Error if any element of the BoundNames of StrictFormalParameters also occurs in the LexicallyDeclaredNames of FunctionBody.

GeneratorDeclaration: function * BindingIdentifier (FormalParameters) { FunctionBody }

and

GeneratorExpression: function * BindingIdentifierOpt (FormalParameters) { FunctionBody }

• If the source code matching this production is strict code, the Early Error rules for StrictFormalParameters: FormalParameters are applied.

• It is a Syntax Error if IsSimpleParameterList of FormalParameters is false and any element of the BoundNames of FormalParameters also occurs in the VarDeclaredNames of FunctionBody.

• It is a Syntax Error if any element of the BoundNames of FormalParameters also occurs in the LexicallyDeclaredNames of FunctionBody.

Static Semantics: BoundNames

GeneratorDeclaration: function * BindingIdentifier (FormalParameters) { FunctionBody }

Commented [AWB10102]: This actually doesn't accomplish anything because a similar annotation within MemberExpression takes care of the possibility of a leading RegExp here.
1. Return the BoundNames of BindingIdentifier.

**Static Semantics: Contains**

With parameter `symbol`,

```javascript
GeneratorDeclaration: function * BindingIdentifier (FormalParameters) { FunctionBody }
```

1. Return `false`.

```javascript
GeneratorExpression: function * BindingIdentifieropt (FormalParameters) { FunctionBody }
```

1. Return `false`.

**NOTE** Static semantic rules that depend upon substructure generally do not look into function definitions.

**Static Semantics: IsConstantDeclaration**

```javascript
GeneratorDeclaration: function * BindingIdentifier (FormalParameters) { FunctionBody }
```

1. Return `false`.

**Static Semantics: LexicallyDeclaredNames**

```javascript
GeneratorDeclaration: function * BindingIdentifier (FormalParameters) { FunctionBody }
```

1. Return the BoundNames of BindingIdentifier.

**Static Semantics: PropName**

```javascript
GeneratorMethod: * PropertyName (FormalParameters) { FunctionBody }
```

1. Return `PropName` of PropertyName.

**Static Semantics: ReferencesSuper**

```javascript
GeneratorMethod: * PropertyName (FormalParameters) { FunctionBody }
```

1. If `FormalParameters` Contains `super` is `true`, then return `true`.
2. Return `FunctionBody` Contains `super`.

**Static Semantics: VarDeclaredNames**

```javascript
GeneratorDeclaration: function * BindingIdentifier (FormalParameters) { FunctionBody }
```

1. Return an empty List.

### 14.4.1.2 Runtime Semantics

**NOTE:** Abstract operations relating to generator objects are defined in 25.4.3.

**Runtime Semantics: EvaluateBody**

With parameter `functionObject`.

```javascript
GeneratorBody: FunctionBody
```

1. Assert: A Function Environment Record containing a this binding has already been activated as the current environment.
2. Let env be the result of the GetThisEnvironment abstract operation.
3. Let G be the result of calling the GetThisBinding concrete method of env.
4. If Type(G) is not Object or if Type(G) is Object and G does not have a [[GeneratorState]] internal data property or if Type(G) is Object and G has a [[GeneratorState]] internal data property and the value of G’s [[GeneratorState]] internal data property is not undefined, then
   a. Let newG be the result of calling OrdinaryCreateFromConstructor(functionObject, "%GeneratorPrototype%", ([[GeneratorState]], [[GeneratorContext]])).
   b. ReturnIfAbrupt(newG).
   c. Let G be newG.
5. Return the result of GeneratorStart(G, FunctionBody).

GeneratorBody: Comprehension

1. Let G be the result of ObjectCreate("%GeneratorPrototype%", ([[GeneratorState]], [[GeneratorContext]])).
2. ReturnIfAbrupt(G).
3. Assert: the value of G’s [[GeneratorState]] internal data property is undefined.
4. Let startStatus be the result of GeneratorStart(G, Comprehension).
5. ReturnIfAbrupt(startStatus).
6. Return G.

Runtime Semantics: InstantiateFunctionObject

With parameter scope.

GeneratorDeclaration: function * BindingIdentifier ( FormalParameters ) { FunctionBody }

1. If the GeneratorDeclaration is contained in strict code or if its FunctionBody is strict code, then let strict be true. Otherwise let strict be false.
2. Using FunctionBody from the production that is being evaluated, let body be the supplemental syntactic grammar production: GeneratorBody: FunctionBody.
3. Let F be the result of performing the GeneratorFunctionCreate abstract operation with arguments Normal, FormalParameters, body, scope, and strict.
4. Let prototype be the result of the abstract operation ObjectCreate with the intrinsic object %GeneratorPrototype% as its argument.
5. Perform the abstract operation MakeConstructor with arguments F, true, and prototype.
6. Return F.

Runtime Semantics: Property Definition Evaluation

With parameter object and optional parameter functionPrototype.

GeneratorMethod: * PropertyName ( StrictFormalParameters ) { FunctionBody }

1. Let propertyName be the result of evaluating PropertyName.
2. ReturnIfAbrupt(propertyName).
3. Let strict be IsStrict of FunctionBody.
4. Let scope be the running execution context’s LexicalEnvironment.
5. If isComputedPropertyName(propertyName) is true, then
   a. Let duplicateKey be the result of calling the [[HasOwnProperty]] internal method of object with argument propertyName.
   b. ReturnIfAbrupt(duplicateKey).
   c. If duplicateKey is true, then throw a TypeError exception.
6. Using FunctionBody from the production that is being evaluated, let body be the supplemental syntactic grammar production: GeneratorBody: FunctionBody.
7. If ReferencesSuper of GeneratorMethod is true, then
   a. Let closure be the result of performing the GeneratorFunctionCreate abstract operation with arguments Method, StrictFormalParameters, body, scope, and strict and with object as the homeObject optional argument and propertyName as the methodName optional argument.
8. Else
a. Let closure be the result of performing the `GeneratorFunctionCreate` abstract operation with arguments `Method`, `StrictFormalParameters`, body, scope, and `true`.
9. Let `prototype` be the result of the abstract operation `ObjectCreate` with the intrinsic object `%GeneratorPrototype%` as its argument.
10. Perform the abstract operation `MakeConstructor` with arguments `closure`, `true`, and `prototype`.
11. Let `desc` be the Property Descriptor with a `[[Value]]` of `closure`, `[[Writable]]` of `true`, `[[Enumerable]]` of `true`, `[[Configurable]]` of `true`.
12. Let `status` be the result of `DefinePropertyOrThrow`(`object`, `propKey`, `desc`).
13. Return `Abrupt(status)`.
14. Return `NormalCompletion(closure)`.

**Runtime Semantics: Evaluation**

**GeneratorDeclaration:** `function` `*` BindingIdentifier `( FormalParameters )` `{ FunctionBody }
1. Return `NormalCompletion( empty )`.

**GeneratorExpression:** `function` `*` ( FormalParameters ) `{ FunctionBody }
1. If the `GeneratorExpression` is contained in strict code or if its `FunctionBody` is strict code, then let `strict` be `true`.
   Otherwise let `strict` be `false`.
2. Using `FunctionBody` from the production that is being evaluated, let `body` be the supplemental syntactic grammar production `GeneratorBody` `:` `FunctionBody`.
3. Let `scope` be the LexicalEnvironment of the running execution context.
4. Let `closure` be the result of performing the `GeneratorFunctionCreate` abstract operation with arguments `Normal`, `FormalParameters`, `body`, `scope`, and `true`.
5. Let `prototype` be the result of the abstract operation `ObjectCreate` with the intrinsic object `%GeneratorPrototype%` as its argument.
6. Perform the abstract operation `MakeConstructor` with arguments `closure`, `true`, and `prototype`.
7. Return `closure`.

**GeneratorExpression:** `function` `*` BindingIdentifier `( FormalParameters )` `{ FunctionBody }
1. If the `GeneratorExpression` is contained in strict code or if its `FunctionBody` is strict code, then let `strict` be `true`.
   Otherwise let `strict` be `false`.
2. Using `FunctionBody` from the production that is being evaluated, let `body` be the supplemental syntactic grammar production `GeneratorBody` `:` `FunctionBody`.
3. Let `funcEnv` be the result of calling `NewDeclarativeEnvironment` passing the running execution context's Lexical Environment as the argument.
4. Let `envRec` be `funcEnv`'s environment record.
5. Let `name` be `StringValue` of `BindingIdentifier`.
6. Call the `CreateImmutableBindingConcrete` method of `envRec` passing `name` as the argument.
7. Let `closure` be the result of performing the `GeneratorFunctionCreate` abstract operation with arguments `Normal`, `FormalParameters`, `body`, `funcEnv`, and `true`.
8. Let `prototype` be the result of the abstract operation `ObjectCreate` with the intrinsic object `%GeneratorPrototype%` as its argument.
9. Perform the abstract operation `MakeConstructor` with arguments `closure`, `true`, and `prototype`.
10. Call the `InitialiseBindingConcrete` method of `envRec` passing `name` and `closure` as the arguments.
11. Return `NormalCompletion(closure)`.

**NOTE 1** The `BindingIdentifier` in a `GeneratorExpression` can be referenced from inside the `GeneratorExpression`'s `FunctionBody` to allow the generator code to call itself recursively. However, unlike in a `GeneratorDeclaration`, the `BindingIdentifier` in a `GeneratorExpression` cannot be referenced from and does not affect the scope enclosing the `GeneratorExpression`.

**YieldExpression:** `yield` YieldDelegator `AssignmentExpression`
1. Let `exprRef` be the result of evaluating `AssignmentExpression`.
2. Let `value` be `GetValue(exprRef)`.
3. ReturnIfAbrupt(value).
4. If YieldDelegator is present, then
   a. Let iterator be the result of GetIterator(value).
   b. ReturnIfAbrupt(iterator).
   c. Let received be undefined.
   d. Repeat
      i. Let innerResult be the result of IteratorNext(iterator, received).
      ii. ReturnIfAbrupt(innerResult).
      iii. Let done be IteratorComplete(innerResult).
      iv. ReturnIfAbrupt(done).
      v. If done is true, then
         1. Let innerValue be the result of IteratorValue(innerResult).
         2. Return innerValue.
      vi. Let yieldCompletion be the result of GeneratorYield(innerResult).
      vii. Let received be yieldCompletion.[[value]].
      viii. If yieldCompletion.[[type]] is THROW, then
            1. If HasProperty(iterator, "throw") is true, then
               a. Let innerResult be the result of Invoke(iterator, "throw", (received)).
               b. ReturnIfAbrupt(innerResult).
            2. Return yieldCompletion.
   5. Return the result of GeneratorYield(CreateIterResultObject(value, false)).

14.5 Class Definitions

Syntax

ClassDeclaration :
  class BindingIdentifier ClassTail

ClassExpression :
  class BindingIdentifieropt ClassTail

ClassTail :
  ClassHeritageopt { ClassBodyopt }

ClassHeritage :
  extends AssignmentExpression

ClassBody :
  ClassElementList

ClassElementList :
  ClassElement

ClassElement :
  MethodDefinition
    static MethodDefinition

NOTE
A ClassBody is always strict code.

14.5.1.1 Static Semantics

Static Semantics: Early Errors

ClassBody : ClassElementList
  • It is a Syntax Error if PrototypePropertyNameList of ClassElementList contains any duplicate entries, unless the following condition is true for each duplicate entry: The duplicated entry occurs exactly
twice in the list and one occurrence was obtained from a `get` accessor `MethodDefinition` and the other occurrence was obtained from a `set` accessor `MethodDefinition`.

- It is a Syntax Error if `StaticPropertyNameList` of `ClassElementList` contains any duplicate entries, unless the following condition is true for each duplicate entry: The duplicated entry occurs exactly twice in the list and one occurrence was obtained from a `get` accessor `MethodDefinition` and the other occurrence was obtained from a `set` accessor `MethodDefinition`.

**ClassElement : MethodDefinition**

- It is a Syntax Error if PropName of `MethodDefinition` is "`constructor`" and SpecialMethod of `MethodDefinition` is `true`.

**ClassElement : static MethodDefinition**

- It is a Syntax Error if PropName of `MethodDefinition` is "`prototype`".

**Static Semantics: BoundNames**

ClassDeclaration: `class` `BindingIdentifier` `ClassTail`

1. Return the BoundNames of `BindingIdentifier`.

**Static Semantics: ConstructorMethod**

ClassElementList : `ClassElement`

1. If `ClassElement` is the production `ClassElement : ;`, then, return empty.
2. If IsStatic of `ClassElement` is `true`, return empty.
3. If PropName of `ClassElement` is not "`constructor`", return empty.
4. Return `ClassElement`.

ClassElementList : `ClassElementList` `ClassElement`

1. Let head be ConstructorMethod of `ClassElementList`.
2. If head is not empty, return head.
3. If `ClassElement` is the production `ClassElement : ;`, then, return empty.
4. If IsStatic of `ClassElement` is `true`, return empty.
5. If PropName of `ClassElement` is not "`constructor`", return empty.
6. Return `ClassElement`.

**NOTE** Early Error rules ensure that there is only one method definition named "`constructor`" and that it isn't an accessor property or generator definition.

**Static Semantics: Contains**

With parameter `symbol`.

ClassTail : `ClassHeritageopt` `{ ` `ClassBody ` `}`

1. If `symbol` is `ClassBody`, return `true`.
2. If `ClassHeritage` is not present, return `false`.
3. If `symbol` is `ClassHeritage`, return `true`.
4. Return the result of Contains for `ClassHeritage` with argument `symbol`.

**NOTE** Static semantic rules that depend upon substructure generally do not look into class bodies.

**Static Semantics: IsConstantDeclaration**
ClassDeclaration: class BindingIdentifier ClassTail

1. Return false.

Static Semantics: IsStatic

ClassElement : MethodDefinition

1. Return false.

ClassElement : static MethodDefinition

1. Return true.

ClassElement : ;

1. Return false.

Static Semantics: LexicallyDeclaredNames

ClassDeclaration: class BindingIdentifier ClassTail

1. Return the BoundNames of BindingIdentifier.

Static Semantics: PrototypeMethodDefinitions

ClassElementList : ClassElement

5. If ClassElement is the production ClassElement ; ; then return a new empty List.
6. If IsStatic of ClassElement is true, return a new empty List.
7. If PropName of ClassElement is "constructor", return a new empty List.
8. Return a List containing ClassElement.

ClassElementList : ClassElementList ClassElement

7. Let list be PrototypeMethodDefinitions of ClassElementList.
8. If ClassElement is the production ClassElement ; ; then return list.
9. If IsStatic of ClassElement is true, return list.
10. If PropName of ClassElement is "constructor", return ListAppend ClassElement to the end of list.
11. Return list.

Static Semantics: PrototypePropertyNameList

ClassElementList : ClassElement

1. If PropName of ClassElement is empty, return a new empty List.
2. If IsStatic of ClassElement is true, return a new empty List.
3. Return a List containing PropName of ClassElement.

ClassElementList : ClassElementList ClassElement

1. Let list be PrototypePropertyNameList of ClassElementList.
2. If PropName of ClassElement is empty, return list.
3. If IsStatic of ClassElement is true, return list.
4. Append PropName of ClassElement to the end of list.
5. Return list.

Static Semantics: PropName
ClassElement : ;

1. Return empty.

**Static Semantics: StaticPropertyNameList**

ClassElementList : ClassElement

1. If PropName of ClassElement is empty, return a new empty List.
2. If IsStatic of ClassElement is false, return a new empty List.
3. Return a List containing PropName of ClassElement.

ClassElementList : ClassElementList ClassElement

1. Let list be StaticPropertyNameList of ClassElementList.
2. If PropName of ClassElement is empty, return list.
3. If IsStatic of ClassElement is false, return list.
4. Append PropName of ClassElement to the end of list.
5. Return list.

**Static Semantics: StaticMethodDefinitions**

ClassElementList : ClassElement

1. If ClassElement is the production ClassElement : ; then, return a new empty List.
2. If IsStatic of ClassElement is false, return a new empty List.
3. Return a List containing ClassElement.

ClassElementList : ClassElementList ClassElement

1. Let list be StaticMethodDefinitions of ClassElementList.
2. If ClassElement is the production ClassElement : ; then, return list.
3. If IsStatic of ClassElement is false, return list.
4. Append ClassElement to the end of list.
5. Return list.

**Static Semantics: VarDeclaredNames**

ClassDeclaration: class BindingIdentifier ClassTail

1. Return an empty List.

**14.5.1.2 Runtime Semantics**

**Runtime Semantics: ClassDefinitionEvaluation**

With parameter className.

ClassTail : ClassHeritageopt ( ClassBody )

1. If ClassHeritageopt is not present, then
   a. Let protoParent be the intrinsic object %ObjectPrototype%.
   b. Let constructorParent be the intrinsic object %FunctionPrototype%.
2. Else
   a. Let superclass be the result of evaluating ClassHeritage.
   b. ReturnIfAbrupt(superclass).
   c. If superclass is null, then
      i. Let protoParent be null.
      ii. Let constructorParent be the intrinsic object %FunctionPrototype%.
Runtime Semantics: Evaluation

**ClassDeclaration:**  
`class BindingIdentifier ClassTail`

1. Let `value` be the result of `ClassDefinitionEvaluation` of `ClassTail` with argument `undefined`.
2. ReturnIfAbrupt(`value`).
3. Let `env` be the running execution context’s LexicalEnvironment.
4. Let `status` be the result of performing Binding Initialisation for `BindingIdentifier` passing `value` and `env` as the arguments.
5. ReturnIfAbrupt(`status`).
6. Return NormalCompletion(`empty`).

**NOTE**  
The argument to `ClassDefinitionEvaluation` controls whether or not the class that is defined with a `BindingIdentifier` has a local binding to the identifier. Only a `ClassExpression` gets a local name binding of its name. A `ClassDeclaration` never has such a binding. This maintains the parallel with `FunctionExpression` and `FunctionDeclaration`.

**ClassExpression:**  
`class BindingIdentifier#opt ClassTail`

1. If `BindingIdentifier#opt` is not present, then let `className` be `undefined`.
2. Else, let `className` be `StringValue` of `BindingIdentifier`.

---

Commented [AW89103]: Note that this variable currently isn’t used in this algorithm

Commented [AW88104]: As it now stands, this will never be an abrupt completion
3. Let value be the result of ClassDefinitionEvaluation of `ClassTail` with argument `className`.
4. ReturnIfAbrupt(value).
5. Return NormalCompletion(value).

14.6 Tail Position Calls

This material still needs to be reviewed and updated for incorporation here.

14.6.1 Runtime Semantics

Runtime Semantics: PrepareForTailCall

The abstract operation PrepareForTailCall performs the following steps:

1. Let `leafContext` be the running execution context.
2. Suspend `leafContext`.
3. Pop `leafContext` from the execution context context stack. The execution context now on the top of the stack becomes the running execution context, however it remains in its suspended state.
4. Assert: `leafContext` has no further use. It will never be activated as the running execution context.

A tail position call must either release any transient internal resources associated with the currently executing function execution context before invoking the target function or reuse those resources in support of the target function.

NOTE 1 For example, a tail position call should only grow an implementation’s activation record stack by the amount that the size of the target function’s activation record exceeds the size of the calling function’s activation record. If the target function’s activation record is smaller, then the total size of the stack should decrease.

15 ECMAScript Language: Scripts and Modules

15.1 Script

Syntax

Script:
  ScriptBody
ScriptBody:
  OuterStatementList
OuterStatementList:
  OuterItem
OuterItem:
  ModuleDeclaration
  ImportDeclaration
  StatementList

15.1.1 Static Semantics

Static Semantics: Early Errors

ScriptBody: OuterStatementList
• It is a Syntax Error if the LexicallyDeclaredNames of OuterStatementList contains any duplicate entries.
• It is a Syntax Error if any element of the LexicallyDeclaredNames of OuterStatementList also occurs in the VarDeclaredNames of OuterStatementList.
• It is a Syntax Error if OuterStatementList Contains ReturnStatement.
• It is a Syntax Error if OuterStatementList Contains super.
• It is a Syntax Error if OuterStatementList Contains YieldExpression.

NOTE   Additional error conditions relating to conflicting or duplicate declarations are checked during module linking prior to evaluation of a Script. If any such errors are detected the Script is not evaluated.

**Static Semantics: isStrict**

ScriptBody : OuterStatementList

1. If this ScriptBody is contained in strict code or if OuterStatementList is strict code, then return true. Otherwise, return false.

**Static Semantics: LexicallyDeclaredNames**

OuterStatementList : OuterStatementList OuterItem

1. Let names be LexicallyDeclaredNames of OuterStatementList.
2. Append to names the elements of the LexicallyDeclaredNames of OuterItem.
3. Return names.

OuterItem : ModuleDeclaration

1. Return the BoundNames of ModuleDeclaration.

OuterItem : ImportDeclaration

1. Return the BoundNames of ImportDeclaration.

OuterItem : StatementListItem

1. Return TopLevelLexicallyDeclaredNames of StatementListItem.

NOTE   At the top level of a Script, function declarations are treated like var declarations rather than like lexical declarations.

**Static Semantics: LexicallyScopedDeclarations**

OuterStatementList : OuterStatementList OuterItem

1. Let declarations be LexicallyScopedDeclarations of OuterStatementList.
2. Append to declarations the elements of the LexicallyScopedDeclarations of OuterItem.
3. Return declarations.

OuterItem : ModuleDeclaration

1. Return a new List containing ModuleDeclaration.

OuterItem : ImportDeclaration

1. Return a new List containing ImportDeclaration.

OuterItem : StatementListItem

1. Return TopLevelLexicallyScopedDeclarations of StatementListItem.
**Static Semantics: VarDeclaredNames**

\[ \text{OuterStatementList : OuterStatementList OuterItem} \]

1. Let \( \text{names} \) be \( \text{VarDeclaredNames of OuterStatementList} \).
2. Append to \( \text{names} \) the elements of the \( \text{VarDeclaredNames of OuterItem} \).
3. Return \( \text{names} \).

**OuterItem : ModuleDeclaration**

1. Return an empty List.

**OuterItem : ImportDeclaration**

1. Return an empty List.

**OuterItem : StatementListItem**

1. Return \( \text{TopLevelVarDeclaredNames of StatementListItem} \).

**Static Semantics: VarScopedDeclarations**

\[ \text{OuterStatementList : OuterStatementList OuterItem} \]

1. Let \( \text{declarations} \) be \( \text{VarScopedDeclarations of OuterStatementList} \).
2. Append to \( \text{declarations} \) the elements of the \( \text{VarScopedDeclarations of OuterItem} \).
3. Return \( \text{declarations} \).

**OuterItem : ModuleDeclaration**

1. Return a new empty List.

**OuterItem : ImportDeclaration**

1. Return a new empty List.

**OuterItem : StatementListItem**

1. Return the \( \text{TopLevelVarScopedDeclarations of StatementListItem} \).

**15.1.2 Runtime Semantics**

**Runtime Semantics: Script Evaluation**

**With argument realm and deletableBindings.**

\[ \text{Script : ScriptBodyopt} \]

1. The code of this Script is strict mode code if the Directive Prologue (15.2) of its ScriptBody contains a Use Strict Directive or if any of the conditions of 10.1.1 apply. If the code of this Script is strict mode code, ScriptBody is evaluated in the following steps as strict mode code. Otherwise ScriptBody is evaluated in the following steps as non-strict mode code.
2. If ScriptBody is not present, return NormalCompletion(empty).
3. Let globalEnv be realm.[[globalEnv]].
4. Let status be the result of performing Global Declaration Instantiation as described in 15.1.2.1 using ScriptBody, globalEnv, and deletableBindings as arguments.
5. ReturnIfAbrupt(status).
6. Let progCxt be a new ECMAScript code execution context.
7. Set the progCxt’s Realm to realm.
8. Set the progCxt’s VariableEnvironment to globalEnv.
9. Set the progCst’s LexicalEnvironment to globalEnv.
10. If there is a currently running execution context, suspend it.
11. Push progCst on to the execution context stack; progCst is now the running execution context.
12. Let result be the result of evaluating ScriptBody.
13. Suspend progCst and remove it from the execution context stack.
14. If the execution context stack is not empty, resume the context that is now on the top of the execution context stack as the running execution context. Otherwise, the execution context stack is now empty and there is no running execution context.
15. Return result.

NOTE The processes for initiating the evaluation of a Script and for dealing with the result of such an evaluation are defined by an ECMAScript implementation and not by this specification.

Runtime Semantics: Evaluation
OuterStatementList : OuterStatementList OuterItem
1. Let sl be the result of evaluating OuterStatementList.
2. ReturnIfAbrupt(sl).
3. Let s be the result of evaluating OuterItem.
4. If s.[[type]] is throw, return s.
5. If s.[[value]] is empty, let V = sl.[[value]]. otherwise let V = s.[[value]].
6. Return Completion {[[type]]: s.[[type]], [[value]]: V, [[target]]: s.[[target]]}.

NOTE See the 13.1.2 NOTE regarding evaluation of StatementList: StatementList StatementListListItem.

15.1.2.1 Global Declaration Instantiation

NOTE When an execution context is established for evaluating scripts, declarations are instantiated in the current global environment. Each global binding declared in the code is instantiated.

Global Declaration Instantiation is performed as follows using arguments script, env, and deletableBindings, script is the ScriptBody that for which the execution context is being established. env is the global environment record in which bindings are to be created. deletableBindings is true if the bindings that are created should be deletable.

1. Let strict be IsStrict of script.
2. Let lexNames be the LexicallyDeclaredNames of script.
3. Let varNames be the VarDeclaredNames of script.
4. For each name in lexNames, do
   a. If the result of calling env’s HasVarDeclaration concrete method passing name as the argument is true, throw a SyntaxError exception.
   b. If the result of calling env’s HasLexicalDeclaration concrete method passing name as the argument is true, throw a SyntaxError exception.
5. For each name in varNames, do
   a. If the result of calling env’s HasLexicalDeclaration concrete method passing name as the argument is true, throw a SyntaxError exception.
6. Let varDeclarations be the VarScopedDeclarations of script.
7. Let functionsToInitiate be an empty List.
8. Let declaredFunctionNames be an empty List.
9. For each d in varDeclarations, in reverse list order do
   a. If d is a FunctionDeclaration then
      i. NOTE If there are multiple FunctionDeclarations for the same name, the last declaration is used.
      ii. Let fn be the sole element of the BoundNames of d.
      iii. If fn is not an element of declaredFunctionNames, then
          1. Let fnDefinable be the result of calling env’s CanDeclareGlobalFunction concrete method passing fn as the argument.
          2. If fnDefinable is false, throw TypeError exception.
          3. Append fn to declaredFunctionNames.
10. Let declaredVarNames be an empty List.
11. For each d in varDeclarations, do
   a. If d is a VariableStatement then
      i. For each String vn in the BoundNames of d, do
         1. If vn is not an element of declaredFunctionNames, then
            a. Let vnDefinable be the result of calling env’s CanDeclareGlobalVar
               concrete method passing vn and deletableBindings as the arguments.
            b. If vnDefinable is false, throw TypeError exception.
            c. If vn is not an element of declaredVarNames, then
               i. Append vn to declaredVarNames.
   12. NOTE: No abnormal terminations occur after this algorithm step.
13. For each FunctionDeclaration f in functionsToInitialise, do
   a. Let fn be the sole element of the BoundNames of f.
   b. Let fo be the result of performing InstantiateFunctionObject for f with argument env.
   c. Let status be the result of calling env’s CreateGlobalFunctionBinding concrete method passing fn, fo, and deletableBindings as the arguments.
   d. ReturnIfAbrupt(status).
14. For each String vn in declaredVarNames, in list order do
   a. Let status be the result of calling env’s CreateGlobalVarBinding concrete method passing vn and deletableBindings as the argument.
   b. ReturnIfAbrupt(status).
15. Let lexDeclarations be the LexicallyScopedDeclarations of script.
16. For each element d in lexDeclarations do
   a. NOTE: Except for generator function declarations, lexically declared names are only instantiated here but not initialised.
   b. For each element dn of the BoundNames of d do
      i. If IsConstantDeclaration of d is true, then
         1. Let status be the result of calling env’s CreateImmutableBinding concrete method passing dn as the argument.
      ii. Else,
         1. Let status be the result of calling env’s CreateMutableBinding concrete method passing dn and false as the arguments.
      iii. Assert status is never an abrupt completion for lexically declared names.
   c. If d is a GeneratorDeclaration production, then
      i. Let fn be the sole element of the BoundNames of d.
      ii. Let fo be the result of performing InstantiateFunctionObject for d with argument env.
      iii. Let status be the result of calling env’s SetMutableBinding concrete method passing fn, fo, and false as the arguments.
      iv. ReturnIfAbrupt(status).
17. Return NormalCompletion(empt).

NOTE: Early errors specified in 15.1.1 prevent name conflicts between function/var declarations and let/const/class/module declarations as well as redeclaration of let/const/class/module bindings for declaration contained within a single script. However, such conflicts and redeclarations that span more than one script are detected as runtime errors during Global Declaration Instantiation. If any such errors are detected, no bindings are instantiated for the script.

Unlike explicit var or function declarations, properties that are directly created on the global object result in global bindings that may be shadowed by let, const, class, and module declarations.

15.2 Directive Prologues and the Use Strict Directive

A Directive Prologue is the longest sequence of ExpressionStatement productions occurring as the initial StatementListItem productions of a ScriptBody or FunctionBody and where each ExpressionStatement in the sequence consists entirely of a StringLiteral token followed by a semicolon. The semicolon may appear explicitly or may be inserted by automatic semicolon insertion. A Directive Prologue may be an empty sequence.
A Use Strict Directive is an ExpressionStatement in a Directive Prologue whose StringLiteral is either the exact character sequences "use strict" or 'use strict'. A Use Strict Directive may not contain an EscapeSequence or LineContinuation.

A Directive Prologue may contain more than one Use Strict Directive. However, an implementation may issue a warning if this occurs.

NOTE The ExpressionStatement productions of a Directive Prologue are evaluated normally during evaluation of the containing production. Implementations may define implementation specific meanings for ExpressionStatement productions which are not a Use Strict Directive and which occur in a Directive Prologue. If an appropriate notification mechanism exists, an implementation should issue a warning if it encounters in a Directive Prologue an ExpressionStatement that is not a Use Strict Directive or which does not have a meaning defined by the implementation.

15.3 Modules

15.3.1 Module Declaration Instantiation

16 Error Handling and Language Extensions

An implementation must report most errors at the time the relevant ECMAScript language construct is evaluated. An early error is an error that can be detected and reported prior to the evaluation of any construct in the Script containing the error. An implementation must report early errors in a Script prior to the first evaluation of that Script. Early errors in eval code are reported at the time eval is called but prior to evaluation of any construct within the eval code. All errors that are not early errors are runtime errors.

An implementation must treat as an early error any instance of an early error that is specified in a static

An implementation shall not treat other kinds of errors as early errors even if the compiler can prove that a construct cannot execute without error under any circumstances. An implementation may issue an early warning in such a case, but it should not report the error until the relevant construct is actually executed.

An implementation shall report all errors as specified, except for the following:

- An implementation may extend script syntax and regular expression pattern or flag syntax. To permit this, all operations (such as calling eval, using a regular expression literal, or using the Function or RegExp constructor) that are allowed to throw SyntaxError are permitted to exhibit implementation-defined behaviour instead of throwing SyntaxError when they encounter an implementation-defined extension to the script syntax or regular expression pattern or flag syntax.
- An implementation may provide additional types, values, objects, properties, and functions beyond those described in this specification. This may cause constructs (such as looking up a variable in the global scope) to have implementation-defined behaviour instead of throwing an error (such as ReferenceError).
- An implementation may define behaviour other than throwing RangeError for toFixed, toExponential, and toPrecision when the fractionDigits or precision argument is outside the specified range.
17 Standard Built-in ECMAScript Objects

There are certain built-in objects available whenever an ECMAScript program begins execution. One, the global object, is part of the lexical environment of the executing program. Others are accessible as initial properties of the global object.

Unless specified otherwise, a built-in object that is callable as a function is a Built-in Function object with the characteristics described in 9.2.7. Unless specified otherwise, the [[Extensible]] internal data property of a built-in object initially has the value true.

Many built-in objects are functions: they can be invoked with arguments. Some of them furthermore are constructors: they are functions intended for use with the new operator. For each built-in function, this specification describes the arguments required by that function and properties of the Function object. For each built-in constructor, this specification furthermore describes properties of the prototype object of that constructor and properties of specific object instances returned by a new expression that invokes that constructor.

Unless otherwise specified in the description of a particular function, if a function or constructor described in this clause is given fewer arguments than the function is specified to require, the function or constructor shall behave exactly as if it had been given sufficient additional arguments, each such argument being the undefined value.

Unless otherwise specified in the description of a particular function, if a function or constructor described in this clause is given more arguments than the function is specified to allow, the extra arguments are evaluated by the call and then ignored by the function. However, an implementation may define implementation specific behaviour relating to such arguments as long as the behaviour is not the throwing of a TypeError exception that is predicated simply on the presence of an extra argument.

NOTE Implementations that add additional capabilities to the set of built-in functions are encouraged to do so by adding new functions rather than adding new parameters to existing functions.

Unless otherwise specified every built-in prototype object has the Object prototype object, which is the initial value of the expression Object.prototype (19.1.4), as the value of its [[Prototype]] internal data property, except the Object prototype object itself.

None of the built-in functions described in this clause that are not constructors shall implement the [[Construct]] internal method unless otherwise specified in the description of a particular function. The behaviour specified in this clause for each built-in function is the specification of the [[Call]] internal method behaviour for that function with the [[Call]] thisArgument providing the this value and the [[Call]] argumentList providing the named parameters for each built-in function. When a built-in constructor is called as part of a new expression the argumentList parameter of the invoked [[Construct]] internal method provides the values for the built-in constructor's named parameters. None of the built-in functions described in this clause shall have a prototype property unless otherwise specified in the description of a particular function.

This clause generally describes distinct behaviours for when a constructor is "called as a function" and for when it is "called as part of a new expression". The "called as a function" behaviour corresponds to the invocation of the constructor's [[Call]] internal method and the "called as part of a new expression" behaviour corresponds to the invocation of the constructor's [[Construct]] internal method.

Every built-in Function object, $F$, described in this clause—whether as a constructor, an ordinary function, or both—has the properties that are defined by performing the following step when the function object is created:

1. Perform the AddRestrictedFunctionProperties (9.1.16.9) abstract operation with argument $F$. 

Commented [AW110]: https://bugs.ecmascript.org/show_bug.cgi?id=155
Every built-in Function object described in this clause—whether as a constructor, an ordinary function, or both—has a length property whose value is an integer. Unless otherwise specified, this value is equal to the largest number of named arguments shown in the subclause headings for the function description, including optional parameters.

NOTE For example, the Function object that is the initial value of the slice property of the String prototype object is described under the subclause heading “String.prototype.slice (start, end)” which shows the two named arguments start and end; therefore the value of the length property of that Function object is 2.

In every case, the length property of a built-in Function object described in this clause has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

Every other data property described in this clause has the attributes { [[Writable]]: true, [[Enumerable]]: false, [[Configurable]]: true } unless otherwise specified.

Every accessor property described in this clause has the attributes { [[Enumerable]]: false, [[Configurable]]: true } unless otherwise specified. If only a get accessor function is described, the set accessor function is the default value, undefined. If only a set accessor is function is described the get accessor is the default value, undefined.

18 The Global Object

The unique global object is created before control enters any execution context.

Unless otherwise specified, the standard built-in properties of the global object have attributes { [[Writable]]: true, [[Enumerable]]: false, [[Configurable]]: true }.

The global object does not have a [[Construct]] internal method; it is not possible to use the global object as a constructor with the new operator.

The global object does not have a [[Call]] internal method; it is not possible to invoke the global object as a function.

The value of the [[Prototype]] internal data property of the global object is implementation-dependent.

In addition to the properties defined in this specification the global object may have additional host defined properties. This may include a property whose value is the global object itself; for example, in the HTML document object model the window property of the global object is the global object itself.

18.1 Value Properties of the Global Object

18.1.1 Infinity

The value of Infinity is \( +\infty \) (see 6.1.5). This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

18.1.2 NaN

The value of NaN is NaN (see 6.1.5). This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

18.1.3 undefined

The value of undefined is undefined (see 6.1.1). This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.
18.2 Function Properties of the Global Object

18.2.1 eval (x)

When the eval function is called with one argument \( x \), the following steps are taken:

1. If Type(\( x \)) is not String, return \( x \).
2. Let script be the ECMAScript code that is the result of parsing \( x \), interpreted as UTF-16 encoded Unicode text as described in clause 10, for the goal symbol Script. If the parse fails or any early errors are detected, throw a SyntaxError exception (but see also clause 16).
3. If script Contains ScriptBody.isEval is false, return undefined.
4. Let strictScript be IsStrict of script.
5. If this is a direct call to eval (18.2.1.1), let direct be true, otherwise let direct be false.
6. If direct is true and the code that made the direct call to eval is strict code, then let strictCaller be true. Otherwise, let strictCaller be false.
7. Let ctx be the running execution context. If direct is true ctx will be the execution context that performed the direct eval. If direct is false ctx will be the execution context for the invocation of the eval function.
8. Let evalRealm be ctx's Realm.
9. If direct is false and strictScript is false, then
   a. Return the result of Script Evaluation for script with arguments evalRealm and true.
10. If direct is true, strictScript is false, strictCaller is false, and ctx's LexicalEnvironment is the same as evalRealm.[[globalEnv]], then
    a. Return the result of Script Evaluation for script with arguments evalRealm and true.
11. If direct is true, then
    a. If the code that made the direct call to eval is function code and IsValidInFunction of script is false, then throw a SyntaxError exception.
    b. If the code that made the direct call to eval is module code and IsValidInModule of script is false, then throw a SyntaxError exception.
12. If direct is true, then
    a. Let lexEnv be ctx's LexicalEnvironment.
    b. Let varEnv be ctx's VariableEnvironment.
13. Else,
    a. Let lexEnv be evalRealm.[[globalEnv]].
    b. Let varEnv be evalRealm.[[globalEnv]].
14. If strictScript is true or direct is true and strictCaller is true, then
    a. Let strictVarEnv be the result of calling NewDeclarativeEnvironment passing lexEnv as the argument.
    b. Let lexEnv be strictVarEnv.
    c. Let varEnv be strictVarEnv.
15. Let result be the result of performing Eval Declaration Instantiation as described in 18.2.2 with script, varEnv, and lexEnv.
16. ReturnIfAbrupt(result).
17. Let evalCtx be a new ECMAScript code execution context.
18. Set the evalCtx's Realm to evalRealm.
19. Set the evalCtx's VariableEnvironment to varEnv.
20. Set the evalCtx's LexicalEnvironment to lexEnv.
21. If there is a currently running execution context, suspend it.
22. Push evalCtx on to the execution context stack; evalCtx is now the running execution context.
23. Let result be the result of evaluating script.
24. Suspend evalCtx and remove it from the execution context stack.
25. Resume the context that is now on the top of the execution context stack as the running execution context.
26. Return result.

NOTE The eval code cannot instantiate variable or function bindings in the variable environment of the calling context that invoked the eval if either the code of the calling context or the eval code is strict code. Instead such bindings are instantiated in a new VariableEnvironment that is only accessible to the eval code.
18.2.1 Direct Call to Eval

A direct call to the eval function is one that is expressed as a CallExpression that meets all of the following conditions:

- The Reference that is the result of evaluating the MemberExpression in the CallExpression has an environment record as its base value and its reference name is "eval".
- If the base value of the Reference has true as its withEnvironment value, then its binding object is an object that uses the ordinary definition of the [[Invoke]] internal method (9.1.11)
- The result of calling the abstract operation GetValue with that Reference as the argument is the standard built-in function defined in 18.2.1.

18.2.1.2 Eval Declaration Instantiation

18.2.2 isFinite (number)

Returns false if the argument coerces to NaN, +∞, or −∞, and otherwise returns true.

1. Let num be ToNumber(number).
2. ReturnIfAbrupt(num).
3. If num is NaN, +∞, or −∞, return false.
4. Otherwise, return true.

18.2.3 isNaN (number)

Returns true if the argument coerces to NaN, and otherwise returns false.

1. Let num be ToNumber(number).
2. ReturnIfAbrupt(num).
3. If num is NaN, return true.
4. Otherwise, return false.

NOTE A reliable way for ECMAScript code to test if a value X is a NaN is an expression of the form X !== X. The result will be true if and only if X is a NaN.

18.2.4 parseFloat (string)

The parseFloat function produces a Number value dictated by interpretation of the contents of the string argument as a decimal literal.

When the parseFloat function is called, the following steps are taken:

1. Let inputString be ToString(string).
2. ReturnIfAbrupt(inputString).
3. Let trimmedString be a substring of inputString consisting of the leftmost character that is not a StrWhiteSpaceChar and all characters to the right of that character. (In other words, remove leading white space.) If inputString does not contain any such characters, let trimmedString be the empty string.
4. If neither trimmedString nor any prefix of trimmedString satisfies the syntax of a StrDecimalLiteral (see 7.1.3.1), return NaN.
5. Let numberString be the longest prefix of trimmedString, which might be trimmedString itself, that satisfies the syntax of a StrDecimalLiteral.
6. Return the Number value for the MV of numberString.

NOTE parseFloat may interpret only a leading portion of string as a Number value; it ignores any characters that cannot be interpreted as part of the notation of an decimal literal, and no indication is given that any such characters were ignored.
18.2.5 parseInt (string, radix)

The `parseInt` function produces an integer value dictated by interpretation of the contents of the `string` argument according to the specified `radix`. Leading white space in `string` is ignored. If `radix` is `undefined` or 0, it is assumed to be 10 except when the number begins with the character pairs 0x or 0X, in which case a radix of 16 is assumed. If `radix` is 16, the number may also optionally begin with the character pairs 0x or 0X.

When the `parseInt` function is called, the following steps are taken:

1. Let `inputString` be `ToString(string)`.
2. ReturnIfAbrupt(`string`).
3. Let `S` be a newly created substring of `inputString` consisting of the first character that is not a `StrWhiteSpaceChar` and all characters following that character. (In other words, remove leading white space.) If `inputString` does not contain any such characters, let `S` be the empty string.
4. Let `sign` be 1.
5. If `S` is not empty and the first character of `S` is a minus sign `-`, let `sign` be `-1`.
6. If `S` is not empty and the first character of `S` is a plus sign `+` or a minus sign `-`, then remove the first character from `S`.
7. Let `R = ToInt32(radix)`.
8. ReturnIfAbrupt(`R`).
9. Let `stripPrefix` be `true`.
10. If `R ≠ 0`, then
   a. If `R < 2` or `R > 36`, then return `NaN`.
   b. If `R ≠ 16`, let `stripPrefix` be `false`.
11. Else `R = 0`,
    a. Let `R = 10`.
12. If `stripPrefix` is `true`, then
   a. If the length of `S` is at least 2 and the first two characters of `S` are either “0x” or “0X”, then remove the first two characters from `S` and let `R = 16`.
13. If `S` contains any character that is not a radix-`R` digit, then let `Z` be the substring of `S` consisting of all characters before the first such character; otherwise, let `Z` be `S`.
14. If `Z` is empty, return `NaN`.
15. Let `mathInt` be the mathematical integer value that is represented by `Z` in radix-`R` notation, using the letters A-Z and a-z for digits with values 10 through 35. (However, if `R` is 10 and `Z` contains more than 20 significant digits, every significant digit after the 20th may be replaced by a 0 digit, at the option of the implementation; and if `R` is not 2, 4, 8, 10, 16, or 32, then `mathInt` may be an implementation-dependent approximation to the mathematical integer value that is represented by `Z` in radix-`R` notation.)
16. Let `number` be the Number value for `mathInt`.
17. Return `sign × number`.

**NOTE** `parseInt` may interpret only a leading portion of `string` as an integer value; it ignores any characters that cannot be interpreted as part of the notation of an integer, and no indication is given that any such characters were ignored.

18.3 URI Handling Function Properties

Uniform Resource Identifiers, or URIs, are Strings that identify resources (e.g. web pages or files) and transport protocols by which to access them (e.g. HTTP or FTP) on the Internet. The ECMAScript language itself does not provide any support for using URIs except for functions that encode and decode URIs as described in 18.3.1, 18.3.2, 18.3.3 and 18.3.3.

**NOTE** Many implementations of ECMAScript provide additional functions and methods that manipulate web pages; these functions are beyond the scope of this standard.

A URI is composed of a sequence of components separated by component separators. The general form is:

```
Scheme : First / Second ; Third ? Fourth
```
where the italicised names represent components and ":", "/", ";" and "?" are reserved characters used as separators. The `encodeURI` and `decodeURI` functions are intended to work with complete URIs; they assume that any reserved characters in the URI are intended to have special meaning and so are not encoded. The `encodeURIComponent` and `decodeURIComponent` functions are intended to work with the individual component parts of a URI; they assume that any reserved characters represent text and so must be encoded so that they are not interpreted as reserved characters when the component is part of a complete URI.

The following lexical grammar specifies the form of encoded URIs.

**Syntax**

```plaintext
uri ::=
  uriCharactersopt

uriCharacters ::= uriCharacter uriCharactersopt

uriCharacter ::=
  uriReserved
  uriUnescaped
  uriEscaped

uriReserved ::= one of
  ; / ? : @ & = + $ ,

uriUnescaped ::= uriAlpha
  DecimalDigit
  uriMark

uriEscaped ::= % HexDigit HexDigit

uriAlpha ::= one of
  a b c d e f g h i j k l m n o p q r s t u v w x y z
  A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

uriMark ::= one of
  - _ ! ~ * ' ( )
```

**NOTE** The above syntax is based upon RFC 2396 and does not reflect changes introduced by the more recent RFC 3986.

**Runtime Semantics**

When a character to be included in a URI is not listed above or is not intended to have the special meaning sometimes given to the reserved characters, that character must be encoded. The character is transformed into its UTF-8 encoding, with surrogate pairs first converted from UTF-16 to the corresponding code point value. (Note that for code units in the range [0,127] this results in a single octet with the same value.) The resulting sequence of octets is then transformed into a String with each octet represented by an escape sequence of the form "%xx".

**Runtime Semantics: Encode Abstract Operation**

The encoding and escaping process is described by the abstract operation `Encode` taking two String arguments `string` and `unescapedSet`.

1. Let `strLen` be the number of characters in `string`.
2. Let `R` be the empty String.

DRAFT
3. Let \( k \) be 0.
4. Repeat
   a. If \( k \) equals \( \text{strLen} \), return \( R \).
   b. Let \( C \) be the character at position \( k \) within \( \text{string} \).
   c. If \( C \) is in \( \text{unescapeSet} \), then
      i. Let \( S \) be a String containing only the character \( C \).
      ii. Let \( R \) be a new String value computed by concatenating the previous value of \( R \) and \( S \).
   d. Else \( C \) is not in \( \text{unescapeSet} \),
      i. If the code unit value of \( C \) is not less than 0xDC00 and not greater than 0xDFFF, throw a \text{URIError} exception.
      ii. If the code unit value of \( C \) is less than 0xD800 or greater than 0xDBFF, then
         1. Let \( V \) be the code unit value of \( C \).
         2. If \( k \) is not equal to \( \text{strLen} \), throw a \text{URIError} exception.
         3. Let \( \text{kChar} \) be the code unit value of the character at position \( k \) within \( \text{string} \).
         4. If \( \text{kChar} \) is less than 0xDC00 or greater than 0xDFFF, throw a \text{URIError} exception.
         5. Let \( V \) be \(((\text{the code unit value of } C) - 0xD800) \times 0x400 + (\text{kChar} - 0xDC00) + 0x10000)\).
      iv. Let \( \text{Octets} \) be the array of octets resulting by applying the UTF-8 transformation to \( V \), and let \( L \) be the array size.
      v. Let \( j \) be 0.
      vi. Repeat, while \( j < L \)
         1. Let \( j\text{Octet} \) be the value at position \( j \) within \( \text{Octets} \).
         2. Let \( S \) be a String containing three characters "%XY" where \( XY \) are two uppercase hexadecimal digits encoding the value of \( j\text{Octet} \).
         3. Let \( R \) be a new String value computed by concatenating the previous value of \( R \) and \( S \).
         4. Increase \( j \) by 1.
   e. Increase \( k \) by 1.

Runtime Semantics: Decode Abstract Operation

The unescaping and decoding process is described by the abstract operation Decode taking two String arguments \( \text{string} \) and \( \text{reservedSet} \).

1. Let \( \text{strLen} \) be the number of characters in \( \text{string} \).
2. Let \( R \) be the empty String.
3. Let \( k \) be 0.
4. Repeat
   a. If \( k \) equals \( \text{strLen} \), return \( R \).
   b. Let \( C \) be the character at position \( k \) within \( \text{string} \).
   c. If \( C \) is not ‘%’, then
      i. Let \( S \) be the String containing only the character \( C \).
   d. Else \( C \) is ‘%’,
      i. Let \( \text{start} \) be \( k \).
      ii. If \( k + 2 \) is greater than or equal to \( \text{strLen} \), throw a \text{URIError} exception.
      iii. If the characters at position \( (k+1) \) and \( (k + 2) \) within \( \text{string} \) do not represent hexadecimal digits, throw a \text{URIError} exception.
      iv. Let \( B \) be the 8-bit value represented by the two hexadecimal digits at position \( (k + 1) \) and \( (k + 2) \).
   v. Increment \( k \) by 2.
   vi. If the most significant bit in \( B \) is 0, then
      1. Let \( C \) be the character with code unit value \( B \).
      2. If \( C \) is not in \( \text{reservedSet} \), then
         a. Let \( S \) be the String containing only the character \( C \).
      3. Else \( C \) is in \( \text{reservedSet} \),
         a. Let \( S \) be the substring of \( \text{string} \) from position \( \text{start} \) to position \( k \) included.
   vii. Else the most significant bit in \( B \) is 1,
1. Let \( n \) be the smallest non-negative number such that \((B < n) & 0x80\) is equal to 0.
2. If \( n \) equals 1 or \( n \) is greater than 4, throw a `URIError` exception.
3. Let `Octets` be an array of 8-bit integers of size \( n \).
4. Put \( B \) into `Octets` at position 0.
5. If \( k + (3 \times (n - 1)) \) is greater than or equal to `strLen`, throw a `URIError` exception.
6. Let \( j \) be 1.
7. Repeat, while \( j < n 
\)
   a. Increment \( k \) by 1.
   b. If the character at position \( k \) within `string` is not “\%”, throw a `URIError` exception.
   c. If the characters at position \( (k + 1) \) and \( (k + 2) \) within `string` do not represent hexadecimal digits, throw a `URIError` exception.
   d. Let \( B \) be the 8-bit value represented by the two hexadecimal digits at position \( (k + 1) \) and \( (k + 2) \).
   e. If the two most significant bits in \( B \) are not 10, throw a `URIError` exception.
   f. Increment \( k \) by 2.
   g. Put \( B \) into `Octets` at position \( j \).
   h. Increment \( j \) by 1.

8. Let \( V \) be the value obtained by applying the UTF-8 transformation to `Octets`, that is, from an array of octets into a 24-bit value. If `Octets` does not contain a valid UTF-8 encoding of a Unicode code point throw an `URIError` exception.

9. If \( V < 0x10000 \), then
   a. Let \( C \) be the character with code unit value \( V \).
   b. If \( C \) is not in `reservedSet`, then
      i. Let \( S \) be the string containing only the character \( C \).
   c. Else \( C \) is in `reservedSet`.
      i. Let \( S \) be the substring of `string` from position \( start \) to position \( k \) included.

10. Else \( V \geq 0x10000 \), then
    a. Let \( L \) be \(((V - 0x10000) & 0x3FF) + 0xDC00\).
    b. Let \( M \) be \(((V - 0x10000) >>> 10) & 0x3FF) + 0xD800\).
    c. Let \( H \) be the string containing the two characters with code unit values \( L \) and \( M \).
    d. Let \( R \) be a new string value computed by concatenating the previous value of \( R \) and \( S \).
    e. Increase \( k \) by 1.

---

Where

\[ uu \cdot vv \cdot vv \cdot vv + 1 \]

to account for the addition of 0x10000 as in Surrogates, section 3.7, of the Unicode Standard.

The range of code unit values 0xD800-0xDFFF is used to encode surrogate pairs; the above transformation combines a UTF-16 surrogate pair into a UTF-32 representation and encodes the resulting 21-bit value in UTF-8. Decoding reconstructs the surrogate pair.

RFC 3629 prohibits the decoding of invalid UTF-8 octet sequences. For example, the invalid sequence C0 80 must not decode into the character U+0000. Implementations of the Decode algorithm are required to throw a URIError when encountering such invalid sequences.

### 18.3.1 decodeURI( encodedURI )

The decodeURI function computes a new version of a URI in which each escape sequence and UTF-8 encoding of the sort that might be introduced by the encodeURI function is replaced with the character that it represents. Escape sequences that could not have been introduced by encodeURI are not replaced.

When the decodeURI function is called with one argument encodedURI, the following steps are taken:

1. Let uriString be ToString(encodedURI).
2. ReturnIfAbrupt(uriString).
3. Let reservedURISet be a String containing one instance of each character valid in uriReserved plus “#”.
4. Return the result of calling Decode(uriString, reservedURISet)

**NOTE** The character “#” is not decoded from escape sequences even though it is not a reserved URI character.

### 18.3.2 decodeURIComponent( encodedURIComponent )

The decodeURIComponent function computes a new version of a URI in which each escape sequence and UTF-8 encoding of the sort that might be introduced by the encodeURIComponent function is replaced with the character that it represents. Escape sequences that could not have been introduced by encodeURIComponent are not replaced.

When the decodeURIComponent function is called with one argument encodedURIComponent, the following steps are taken:

1. Let componentString be ToString(encodedURIComponent).
2. ReturnIfAbrupt(componentString).
3. Let reservedURIComponentSet be the empty String.
4. Return the result of calling Decode(componentString, reservedURIComponentSet)

### 18.3.3 encodeURI( uri )

The encodeURI function computes a new version of a URI in which each instance of certain characters is replaced by one, two, three, or four escape sequences representing the UTF-8 encoding of the character.

When the encodeURI function is called with one argument uri, the following steps are taken:

1. Let uriString be ToString(uri).
2. ReturnIfAbrupt(uriString).
3. Let unescapedURISet be a String containing one instance of each character valid in uriReserved and uriUnescaped plus “#”.
4. Return the result of calling Encode(uriString, unescapedURISet)

**NOTE** The character “#” is not encoded to an escape sequence even though it is not a reserved or unescaped URI character.
18.3.4 encodeURIComponent (uriComponent)

The `encodeURIComponent` function computes a new version of a URI in which each instance of certain characters is replaced by one, two, three, or four escape sequences representing the UTF-8 encoding of the character.

When the `encodeURIComponent` function is called with one argument `uriComponent`, the following steps are taken:

1. Let `componentString` be `ToString(uriComponent)`.  
2. ReturnIfAbrupt(componentString).  
3. Let `unescapeURIComponentSet` be a String containing one instance of each character valid in `uriUnescaped`.  
4. Return the result of calling `Encode(componentString, unescapedURIComponentSet)`

19 Fundamental Objects

19.1 Object Objects

19.1.1 The Object Constructor Called as a Function
When Object is called as a function rather than as a constructor, it performs a type conversion.

19.1.1.1 Object ( [ value ] )
When the object function is called with no arguments or with one argument value, the following steps are taken:
1. If value is null, undefined or not supplied, return the result of the abstract operation ObjectCreate with the intrinsic object %ObjectPrototype% as its argument.
2. Return ToObject(value).

19.1.2 The Object Constructor
When object is called as part of a new expression, it is a constructor that may create an object.

19.1.2.1 new Object ( [ value ] )
When the object constructor is called with no arguments or with one argument value, the following steps are taken:
1. If value is supplied, then
   a. If Type(value) is Object, then return value.
b. If Type(value) is String, return ToObject(value).
c. If Type(value) is Boolean, return ToObject(value).
d. If Type(value) is Number, return ToObject(value).

2. Assert: The argument value was not supplied or its type was Null or Undefined.
3. Return the result of the abstract operation ObjectCreate with the intrinsic object %ObjectPrototype% as its argument.

19.1.3 Properties of the Object Constructor

The value of the [[Prototype]] internal data property of the Object constructor is the standard built-in Function prototype object.

Besides the length property (whose value is 1), the Object constructor has the following properties:

19.1.3.1 Object.assign (target, source)

<table>
<thead>
<tr>
<th>TODO</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Only enumerable own properties of source</td>
</tr>
<tr>
<td>• Invoke [[Get]] on property list derived from source, for each property in list [[Put]] on target</td>
</tr>
<tr>
<td>• private names are not copied</td>
</tr>
<tr>
<td>• unique names are copied</td>
</tr>
<tr>
<td>• super mechanism (rebind super)</td>
</tr>
<tr>
<td>• Returns modified &quot;target&quot;</td>
</tr>
</tbody>
</table>

19.1.3.2 Object.create (O, Properties)

The create function creates a new object with a specified prototype. When the create function is called, the following steps are taken:

1. If Type(O) is not Object or Null throw a TypeError exception.
2. Let obj be the result of the abstract operation ObjectCreate with argument O.
3. If the argument Properties is present and not undefined, then
   a. Return the result of the abstract operation ObjectDefineProperties(obj, Properties).
4. Return obj.

19.1.3.3 Object.defineProperties (O, Properties)

The defineProperties function is used to add own properties and/or update the attributes of existing own properties of an object. When the defineProperties function is called, the following steps are taken:

1. Return the result of the abstract operation ObjectDefineProperties with arguments O and Properties.

Runtime Semantics: ObjectDefineProperties Abstract Operation

The abstract operation ObjectDefineProperties with arguments O and Properties performs the following steps:

1. If Type(O) is not Object throw a TypeError exception.
2. Let props be ToObject(Properties).
3. Let names be an internal list containing the keys of each enumerable own property of props.
4. Let descriptors be an empty internal List.
5. For each element P of names in list order,
a. Let `descObj` be the result of `Get(props, P)`.
   b. ReturnIfAbrupt(`descObj`).
   c. Let `desc` be the result of calling `ToPropertyDescriptor` with `descObj` as the argument.
      d. ReturnIfAbrupt(`desc`).
      e. Append the pair (a two element List) consisting of `P` and `desc` to the end of `descriptors`.

6. Let `pendingException` be `undefined`.
7. For each pair from `descriptors` in list order,
   a. Let `P` be the first element of `pair`.
   b. Let `desc` be the second element of `pair`.
   c. Let `status` be the result of `DefinePropertyOrThrow(O, P, desc)`.
      d. If `status` is an abrupt completion then
         i. If `pendingException` is `undefined`, then set `pendingException` to `status`.
   8. ReturnIfAbrupt(`pendingException`).

If an implementation defines a specific order of enumeration for the `for-in` statement, that same enumeration order must be used to order the list elements in step 3 of this algorithm.

NOTE An exception in defining an individual property in step 7 does not terminate the process of defining other properties. All valid property definitions are processed.

19.1.3.4 `Object.defineProperty ( O, P, Attributes )`

The `defineProperty` function is used to add an own property and/or update the attributes of an existing own property of an object. When the `defineProperty` function is called, the following steps are taken:

1. If Type(`O`) is not Object throw a `TypeError` exception.
2. Let `key` be `ToPropertyKey(P)`.
3. ReturnIfAbrupt(`key`).
4. Let `desc` be the result of calling `ToPropertyDescriptor(Attributes)`.
5. ReturnIfAbrupt(`desc`).
6. Let `success` be the result of `DefinePropertyOrThrow(O, key, desc)`.
7. ReturnIfAbrupt(`success`).
8. Return `O`.

19.1.3.5 `Object.freeze ( O )`

When the `freeze` function is called, the following steps are taken:

1. If Type(`O`) is not Object throw, return `O`.
2. Let `status` be the result of `SetIntegrityLevel(O, "frozen")`.
3. ReturnIfAbrupt(`status`).
4. If `status` is false, throw a `TypeError` exception.
5. Return `O`.

19.1.3.6 `Object.getOwnPropertyDescriptor ( O, P )`

When the `getOwnPropertyDescriptor` function is called, the following steps are taken:

1. Let `obj` be `ToObject(O)`.
2. ReturnIfAbrupt(`obj`).
3. Let `key` be `ToPropertyKey(P)`.
4. ReturnIfAbrupt(`key`).
5. Let `desc` be the result of calling the `[[GetOwnProperty]]` internal method of `obj` with argument `key`.
6. ReturnIfAbrupt(`desc`).
7. Return the result of calling `FromPropertyDescriptor(desc)`.

19.1.3.7 `Object.getOwnPropertyKeys ( O )`

When the `getOwnPropertyKeys` function is called with argument `O`, the following steps are taken:
1. Let obj be ToObject(O).
2. ReturnIfAbrupt(obj).
3. Let keys be the result of calling the [[OwnPropertyKeys]] internal method of obj.
4. Return keys.

TODO:
• May need to say something about order of enumeration and post call property additions and deletions

19.1.3.8 Object.getOwnPropertyNames ( O )

When the getOwnPropertyNames function is called, the following steps are taken:
1. Let obj be ToObject(O).
2. ReturnIfAbrupt(obj).
3. Let keys be the result of calling the [[OwnPropertyKeys]] internal method of obj.
4. ReturnIfAbrupt(keys).
5. Let nameList be a new empty List.
6. Let gotAllNames be false.
7. Repeat while gotAllNames is false,
   a. Let next be the result of IteratorNext(keys).
   b. ReturnIfAbrupt(next).
   c. Let done be IteratorComplete(next).
   d. ReturnIfAbrupt(done).
   e. If done is true, then let gotAllNames be true.
   f. Else,
      i. Let nextKey be IteratorValue(next).
      ii. ReturnIfAbrupt(nextKey).
      iii. If Type(nextKey) is String, then
         1. Append nextKey as the last element of nameList.
8. Return CreateArrayFromList(nameList).

19.1.3.9 Object.getPrototypeOf ( O )

When the getPrototypeOf function is called with argument O, the following steps are taken:
1. Let obj be ToObject(O).
2. ReturnIfAbrupt(obj).
3. Return the result of calling the [[GetInheritance]] internal method of obj.

19.1.3.10 Object.is ( value1, value2 )

When the is function is called with arguments value1 and value2 the following steps are taken:
1. Return SameValue(value1, value2).

19.1.3.11 Object.isExtensible ( O )

When the isExtensible function is called with argument O, the following steps are taken:
1. If Type(O) is not Object, return false.
2. Return the result of IsExtensible(O).

19.1.3.12 Object.isFrozen ( O )

When the isFrozen function is called with argument O, the following steps are taken:
1. If Type(O) is not Object, return true.
2. Return TestIntegrityLevel(O, "frozen").
19.1.3.13 Object.isSealed ( O )

When the isSealed function is called with argument O, the following steps are taken:

1. If Type(O) is not Object, return true.
2. Return TestIntegrityLevel(O, "sealed").

19.1.3.14 Object.keys ( O )

When the keys function is called with argument O, the following steps are taken:

1. Let obj be ToObject(O).
2. ReturnIfAbrupt(obj).
3. Let keys be the result of calling the [[OwnPropertyKeys]] internal method of obj.
4. ReturnIfAbrupt(keys).
5. Let nameList be a new empty List.
6. Let gotAllNames be false.
7. Repeat while gotAllNames is false,
   a. Let next be the result of IteratorNext(keys).
   b. ReturnIfAbrupt(next).
   c. Let done be IteratorComplete(next).
   d. ReturnIfAbrupt(done).
   e. If done is true, then let gotAllNames be true.
   f. Else,
      i. Let nextKey be IteratorValue(next).
      ii. ReturnIfAbrupt(nextKey).
      iii. If Type(nextKey) is String, then
           1. Let desc be the result of calling the [[GetProperty]] internal method of O with argument nextKey.
           2. ReturnIfAbrupt(desc).
           3. If desc is not undefined and desc.[[Enumerable]] is true, then
              a. Append nextKey as the last element of nameList.
     8. Return CreateArrayFromList(nameList).

If an implementation defines a specific order of enumeration for the for-in statement, the same order must be used for the elements of the array returned in step 7.

19.1.3.15 Object.mixin ( target, source )

Don't have TC39 consensus on including this or its name. However, there appears to be strong interest both within TC39 and on es-discuss and reasonable use cases. “mixin” seems to be the favorite name from es-discuss, although concerns have been raised that it might clash with some existing libraries.

TODO:
- All non-private properties of source
- Uses [[GetOwnProperty]]/[[DefineOwnProperty]]
- private symbols are not copied
- non-symbols are copied
- super mechanism (rebind super)
- Returns modified "target"
19.1.3.16 Object.preventExtensions ( O )

When the `preventExtensions` function is called, the following steps are taken:

1. If `Type(O)` is not Object, return O.
2. Let `status` be the result of calling the `[[PreventExtensions]]` internal method of `O`.
3. ReturnIfAbrupt(`status`).
4. If `status` is false, throw a `TypeError` exception.
5. Return `O`.

19.1.3.17 Object.prototype

The initial value of `object.prototype` is the standard built-in Object prototype object (19.1.4).

This property has the attributes `{[[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

19.1.3.18 Object.seal ( O )

When the `seal` function is called, the following steps are taken:

1. If `Type(O)` is not Object, return O.
2. Let `status` be the result of `SetIntegrityLevel( O, 'sealed' )`.
3. ReturnIfAbrupt(`status`).
4. If `status` is false, throw a `TypeError` exception.
5. Return `O`.

19.1.3.19 Object.setPrototypeOf ( O, proto )

When the `setPrototypeOf` function is called with arguments `O` and `proto`, the following steps are taken:

1. Let `O` be `CheckObjectCoercible(O)`.
2. ReturnIfAbrupt(`O`).
3. If `Type(proto)` is neither Object or Null, then throw a `TypeError` exception.
4. If `Type(O)` is not Object, then return `O`.
5. Let `status` be the result of calling the `[[SetInheritance]]` internal method of `O` with argument `proto`.
6. ReturnIfAbrupt(`status`).
7. If `status` is false, then throw a `TypeError` exception.
8. Return `O`.

19.1.4 Properties of the Object Prototype Object

The Object prototype object is an ordinary object.

The value of the `[[Prototype]]` internal data property of the Object prototype object is `null` and the initial value of the `[[Extensible]]` internal data property is `true`.

19.1.4.1 Object.prototype.constructor

The initial value of `Object.prototype.constructor` is the standard built-in `Object` constructor.

19.1.4.2 Object.prototype.hasOwnProperty (V)

When the `hasOwnProperty` method is called with argument `V`, the following steps are taken:

1. Let `P` be ToPropertyKey(`V`).
2. ReturnIfAbrupt(`P`).
3. Let `O` be the result of calling `ToObject` passing the `this` value as the argument.
4. ReturnIfAbrupt(`O`).
5. Return the result of calling the `[[HasOwnProperty]]` internal method of `O` passing `P` as the argument.
NOTE The ordering of steps 1 and 3 is chosen to ensure that any exception that would have been thrown by step 1 in previous editions of this specification will continue to be thrown even if the this value is `undefined` or null.

19.1.4.3 Object.prototype.isPrototypeOf (V)

When the `isPrototypeOf` method is called with argument `V`, the following steps are taken:

1. If `V` is not an object, return `false`.
2. Let `O` be the result of calling `ToObject` passing the `this` value as the argument.
3. ReturnIfAbrupt(`O`).
4. Repeat
   a. Let `V` be the result of calling the `[[GetInheritance]]` internal method of `V` with no arguments.
   b. if `V` is `null`, return `false`
   c. If `SameValue(O, V)` is `true`, then return `true`.

NOTE The ordering of steps 1 and 2 is chosen to preserve the behavior specified by previous editions of this specification for the case where `V` is not an object and the `this` value is `undefined` or null.

19.1.4.4 Object.prototype.propertyIsEnumerable (V)

When the `propertyIsEnumerable` method is called with argument `V`, the following steps are taken:

1. Let `P` be `ToString(V)`.
2. ReturnIfAbrupt(`P`).
3. Let `O` be the result of calling `ToObject` passing the `this` value as the argument.
4. ReturnIfAbrupt(`O`).
5. Let `desc` be the result of calling the `[[GetOwnProperty]]` internal method of `O` passing `P` as the argument.
6. If `desc` is `undefined`, return `false`.

NOTE 1 This method does not consider objects in the prototype chain.

NOTE 2 The ordering of steps 1 and 2 is chosen to ensure that any exception that would have been thrown by step 1 in previous editions of this specification will continue to be thrown even if the `this` value is `undefined` or null.

19.1.4.5 Object.prototype.toLocaleString ()

When the `toLocaleString` method is called, the following steps are taken:

1. Let `O` be the `this` value.
2. Return the result of `Invoke(O, "toString")`.

NOTE 1 This function is provided to give all Objects a generic `toLocaleString` interface, even though not all may use it. Currently, `Array`, `Number`, and `Data` provide their own locale-sensitive `toLocaleString` methods.

NOTE 2 The first parameter to this function is likely to be used in a future version of this standard; it is recommended that implementations do not use this parameter position for anything else.

19.1.4.6 Object.prototype.toString ()

When the `toString` method is called, the following steps are taken:

1. If the `this` value is `undefined`, return "[object Undefined]".
2. If the `this` value is `null`, return "[object Null]". Let `O` be the result of calling `ToObject` passing the `this` value as the argument.
3. If `O` is an exotic Symbol object, then return "[object Symbol]".
4. Else, if `O` is an exotic Array object, then let `builtinTag` be "Array".
5. Else, if `O` is an exotic String object, then let `builtinTag` be "String".
6. Else, if `O` is an exotic Proxy object, then let `builtinTag` be "Proxy".
7. Else, if `O` is an exotic arguments object, then let `builtinTag` be "Arguments".
8. Else, if $O$ is an ordinary function object, a built-in function object, or a bound function exotic object, then let $builtinTag$ be "Function".
9. Else, if $O$ has a [[InternalDataProperty]] internal data property, then let $builtinTag$ be "Error".
10. Else, if $O$ has a [[BooleanData]] internal data property, then let $builtinTag$ be "Boolean".
11. Else, if $O$ has a [[NumberData]] internal data property, then let $builtinTag$ be "Number".
12. Else, if $O$ has a [[DateValue]] internal data property, then let $builtinTag$ be "Date".
13. Else, if $O$ has a [[RegExpMatcher]] internal data property, then let $builtinTag$ be "RegExp".
14. Else, if $O$ has a [[MathTag]] internal data property, then let $builtinTag$ be "Math".
15. Else, if $O$ has a [[JSONTag]] internal data property, then let $builtinTag$ be "JSON".
16. Else, let $builtinTag$ be "Object".
17. Let $hasTag$ be the result of HasProperty($O$, @@toStringTag).
18. ReturnIfAbrupt($hasTag$).
19. If $hasTag$ is false, then let $tag$ be $builtinTag$.
20. Else,
   a. Let $tag$ be the result of Get($O$, @@toStringTag).
   b. If $tag$ is an abrupt completion, let $tag$ be NormalCompletion("???").
   c. Let $tag$ be $tag$.[[value]].
   d. If $Type(tag)$ is not String, let $tag$ be "???".
   e. If $tag$ is any of "Arguments", "Array", "Boolean", "Date", "Error", "Function", "JSON", "Math", "Number", "RegExp", or "String" and $SameValue(tag, builtinTag)$ is false, then let $tag$ be the string value "]-" concatenated with the current value of $tag$.
21. Return the String value that is the result of concatenating the three Strings "[object ", $tag$, and "]".

NOTE Historically, this function was occasionally used to access the string value of the [[Class]] internal data property that was used in previous editions of this specification as a nominal type tag for various built-in objects. The above definition of $toString$ preserves the ability to use it as a reliable test for those specific kinds of built-in objects but does not provide a reliable type testing mechanism for other kinds of built-in or program-defined objects.

19.1.4.7 Object.prototype.valueOf()

When the $valueOf$ method is called, the following steps are taken:
1. Let $O$ be the result of calling ToObject passing the this value as the argument.
2. Return $O$.

19.1.5 Properties of Object Instances

Object instances have no special properties beyond those inherited from the Object prototype object.

19.2 Function Objects

19.2.1 The Function Constructor

The Function constructor is the \%Function\% intrinsic object and the initial value of the Function property of the global object. When Function is called as a function rather than as a constructor, it creates and initialises a new Function object. Thus the function call Function(...) is equivalent to the object creation expression new Function(...) with the same arguments. However, if the this value passed in the call is an Object with an [[Class]] internal data property whose value is undefined, it initialises the this value using the argument values. This permits Function to be used both as factory method and to perform constructor instance initialization.

Function may be subclassed and subclass constructors may perform a super invocation of the Function constructor to initialise subclass instances. However, all syntactic forms for defining function objects create instances of Function. There is no syntactic means to create instances of Function subclasses except for the built-in Generator Function subclass.
19.2.1.1 Function (p₁, p₂, ..., pₙ, body)

The last argument specifies the body (executable code) of a function; any preceding arguments specify formal parameters.

When the Function function is called with some arguments p₁, p₂, ..., pₙ, body (where n might be 0, that is, there are no "p" arguments, and where body might also not be provided), the following steps are taken:

1. Let argCount be the total number of arguments passed to this function invocation.
2. Let P be the empty String.
3. If argCount = 0, let bodyText be the empty String.
4. Else if argCount = 1, let bodyText be that argument.
5. Else argCount > 1,
   a. Let firstArg be the first argument.
   b. Let P be ToString(firstArg).
   c. ReturnIfAbrupt(P).
   d. Let k be 2.
   e. Repeat, while k < argCount
      i. Let nextArg be the k’th argument.
      ii. Let nextArgString be ToString(nextArg).
      iii. ReturnIfAbrupt(nextArgString).
      iv. Let P be the result of concatenating the previous value of P, the String ", " (a comma), and
      nextArgString.
      v. Increase k by 1.
   f. Let bodyText be the k’th argument.
6. Let bodyText be ToString(bodyText).
7. ReturnIfAbrupt(bodyText).
8. Let parameters be the result of parsing P, interpreted as UTF-16 encoded Unicode text as described in clause 10, using FormalParameters as the goal symbol. Throw a SyntaxError exception if the parse fails.
9. Let body be the result of parsing bodyText, interpreted as UTF-16 encoded Unicode text as described in clause 6.1.4, using FunctionBody as the goal symbol. Throw a SyntaxError exception if the parse fails or if any static semantics errors are detected.
10. If body Contains YieldExpression is true, then throw a SyntaxError exception.
11. If IsSimpleParameterList of parameters is false and any element of the BoundNames of parameters also occurs in the VarDeclaredNames of body, then throw a SyntaxError exception.
12. If any element of the BoundNames of parameters also occurs in the LexicallyDeclaredNames of body, then throw a SyntaxError exception.
13. If bodyText is strict mode code (see 10.1.1) then let strict be true, else let strict be false.
14. Let scope be the Global Environment.
15. Let Else be the this value.
16. If Type(F) is not Object or if F does not have a [[Code]] internal data property or if the value of [[Code]] is not undefined, then
   a. Let F be the result of calling FunctionAllocate with argument FunctionPrototype.
17. If the value of F’s [[FunctionKind]] internal data property is not "normal", then throw a TypeError exception.
18. Perform the FunctionInitialize abstract operation with arguments F, Normal, parameters, body, scope, and strict.
19. Perform the abstract operation MakeConstructor with argument F.
20. Return F.

A prototype property is automatically created for every function created using the Function constructor, to provide for the possibility that the function will be used as a constructor.

NOTE It is permissible but not necessary to have one argument for each formal parameter to be specified. For example, all three of the following expressions produce the same result:

new Function("a", "b", "c", "return a+b+c")

new Function("a, b, c", "return a+b+c")

new Function("a,b", "c", "return a+b+c")
19.2.1.2 `new Function (... argumentsList)`

When `Function` is called as part of a `new` expression, it initialises the newly created object.

1. Let `F` be the `Function` function object on which the `new` operator was applied.
2. Let `argumentsList` be the `argumentsList` argument of the `[[Construct]]` internal method that was invoked by the `new` operator.
3. Return the result of `OrdinaryConstruct(F, argumentsList)`.

If `Function` is implemented as an ordinary function object, its `[[Construct]]` internal method will perform the above steps.

19.2.2 Properties of the `Function` Constructor

The `Function` constructor is itself a built-in `Function` object. The value of the `[[Prototype]]` internal data property of the `Function` constructor is `%FunctionPrototype%`, the intrinsic `Function` prototype object (19.2.3).

The value of the `[[Extensible]]` internal data property of the `Function` constructor is `true`.

The `Function` constructor has the following properties:

19.2.2.1 `Function.length`

This is a data property with a value of 1. This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

19.2.2.2 `Function.prototype`

The value of `Function.prototype` is `%FunctionPrototype%`, the intrinsic `Function` prototype object (19.2.3).

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

19.2.2.3 `Function @@create()`

The `@@create` method of an object `F` performs the following steps:

1. Let `F` be the `this` value.
2. Let `proto` be the result of `GetPrototypeFromConstructor(F, "%FunctionPrototype%")`.
3. ReturnIfAbrupt(`proto`).
4. Let `obj` be the result of calling `FunctionAllocate` with argument `proto`.
5. Return `obj`.

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

NOTE The `Function @@create` function is intentionally generic; it does not require that its `this` value be the `Function` constructor object. It can be transferred to other constructor functions for use as a `@@create` method. When used with other constructors, this function will create an exotic function object whose `[[Prototype]]` value is obtained from the associated constructor.

19.2.3 Properties of the `Function.prototype` Object

The `Function.prototype` object is itself a Built-in `Function` object. When invoked, it accepts any arguments and returns `undefined`.

NOTE The `Function.prototype` object is specified to be a function object to ensure compatibility with ECMAScript code that was created prior to the 6th Edition of this specification.
The value of the [[Prototype]] internal data property of the Function prototype object is the intrinsic object %ObjectPrototype%. The initial value of the [[Extensible]] internal data property of the Function prototype object is true.

The function prototype object does not have a prototype property.

The length property of the Function prototype object is 0.

19.2.3.1 Function.prototype.apply (thisArg, argArray)

When the apply method is called on an object func with arguments thisArg and argArray, the following steps are taken:

1. If IsCallable(func) is false, then throw a TypeError exception.
2. If argArray is null or undefined, then
   a. Return the result of calling the [[Call]] internal method of func, providing thisArg as thisArgument and an empty List of arguments as argumentsList.
3. Let argList be the result of CreateListFromArrayLike(argArray).
4. ReturnIfAbrupt(argList).
5. Return the result of calling the [[Call]] internal method of func, providing thisArg as thisArgument and argList as argumentsList.

The length property of the apply method is 2.

NOTE The thisArg value is passed without modification as the this value. This is a change from Edition 3, where a undefined or null thisArg is replaced with the global object and ToObject is applied to all other values and that result is passed as the this value.

19.2.3.2 Function.prototype.bind (thisArg [, arg1 [, arg2, …]])

The bind method takes one or more arguments, thisArg and (optionally) arg1, arg2, etc, and returns a new function object by performing the following steps:

1. Let Target be the this value.
2. If IsCallable(Target) is false, throw a TypeError exception.
3. Let A be a new (possibly empty) internal list consisting of all of the argument values provided after thisArg (arg1, arg2 etc), in order.
4. Let F be the result of the abstract operation BoundFunctionCreate with arguments Target, thisArg, and A.
5. If Target has a [[BoundTargetFunction]] internal data property, then
   a. Let targetLen be the result of Get(Target, "length").
   b. ReturnIfAbrupt(targetLen).
   c. Let L be the larger of 0 and the result of targetLen minus the number of elements of A.
6. Else let L be 0.
7. Call the [[DefineOwnProperty]] internal method of F with arguments "length" and PropertyDescriptor {{[[value]]}: L, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false}.
8. Perform the AddRestrictedFunctionProperties abstract operation with argument F.
9. Return F.

The length property of the bind method is 1.

NOTE Function objects created using Function.prototype.bind are exotic objects. They also do not have a prototype property.

19.2.3.3 Function.prototype.call (thisArg [, arg1 [, arg2, ...]])

When the call method is called on an object func with argument thisArg and optional arguments arg1, arg2 etc, the following steps are taken:

1. If IsCallable(func) is false, then throw a TypeError exception.
2. Let argList be an empty List.
3. If this method was called with more than one argument then in left to right order starting with arg1 append each argument as the last element of argList.
4. Return the result of calling the [[Call]] internal method of func, providing thisArg as thisArgument and argList as argumentsList.

The length property of the call method is 1.

NOTE The thisArg value is passed without modification as the this value. This is a change from Edition 3, where a undefined or null thisArg is replaced with the global object and ToObject is applied to all other values and that result is passed as the this value.

19.2.3.4 Function.prototype.constructor

The initial value of Function.prototype.constructor is the intrinsic object %Function%.

19.2.3.5 Function.prototype.toString ( )

An implementation-dependent String source code representation of the this object is returned. This representation has the syntax of a FunctionDeclaration, FunctionExpression, GeneratorDeclaration, GeneratorExpression, ClassDeclaration, ClassExpression, ArrowFunction, MethodDefinition, or GeneratorMethod depending upon the actual characteristics of the object. In particular that the use and placement of white space, line terminators, and semicolons within the representation String is implementation-dependent.

If the object was defined using ECMAScript code and the returned string representation is in the form of a FunctionDeclaration, FunctionExpression, GeneratorDeclaration, GeneratorExpression, ClassDeclaration, ClassExpression, or ArrowFunction then the representation must be such that if the string is evaluated, using eval in a lexical context that is equivalent to the lexical context used to create the original object, it will result in a new functionally equivalent object. The returned source code must not mention freely any variables that were not mentioned freely by the original function’s source code, even if these “extra” names were originally in scope. If the source code string does meet these criteria then it must be a string for which eval will throw a SyntaxError exception.

The toString function is not generic; it throws a TypeError exception if its this value is not a does not have a [[Call]] internal method. Therefore, it cannot be transferred to other kinds of objects for use as a method.

19.2.3.6 Function.prototype[@@create] ( )

The @@create method of an object F performs the following steps:
1. Return the result of calling OrdinaryCreateFromConstructor(F, "%ObjectPrototype").

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

NOTE This is the default @@create method that is inherited by all ordinary constructor functions that do not explicitly over-ride it.

19.2.3.7 Function.prototype[@@hasInstance] (V)

When the @@hasInstance method of an object F is called with value V, the following steps are taken:
1. Let F be the this value.
2. Return the result of OrdinaryHasInstance(F, V).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

NOTE This is the default implementation of @@hasInstance that most functions inherit. @@hasInstance is called by the instanceof operator to determine whether a value is an instance of a specific constructor. An expression such as

v instanceof F

evaluates as
F@@hasInstance@@(v)
A constructor function can control which objects are recognized as its instances by instanceof by exposing a different @@hasInstance@@ method on the function.

This property is non-writable and non-configurable to prevent tampering that could be used to globally expose the target function of a bound function.

19.2.4 Function Instances

Every function instance is an ordinary function object and has the internal data properties listed in Table 25.

Function instances that correspond to strict mode functions and function instances created using the Function.prototype.bind method (19.2.3.2) have properties named caller and arguments that throw a TypeError exception. An ECMAScript implementation must not associate any implementation specific behaviour with accesses of these properties from strict mode function code.

The Function instances have the following properties:

19.2.4.1 length

The value of the length property is an integer that indicates the typical number of arguments expected by the function. However, the language permits the function to be invoked with some other number of arguments. The behaviour of a function when invoked on a number of arguments other than the number specified by its length property depends on the function. This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

19.2.4.2 prototype

Function instances that can be used as a constructor have a prototype property. Whenever such a function instance is created another ordinary object is also created and is the initial value of the function's prototype property. Unless otherwise specified, the value of the prototype property is used to initialise the [[Prototype]] internal data property of a newly created ordinary object before the Function object is invoked as a constructor for that newly created object.

This property has the attributes { [[Writable]]: true, [[Enumerable]]: false, [[Configurable]]: true }.

NOTE Function objects created using Function.prototype.bind, or by evaluating a MethodDefinition (that is not a GeneratorMethod) or an ArrowFunction grammar production do not have a prototype property.

19.3 Boolean Objects

19.3.1 The Boolean Constructor

The Boolean constructor is the %Boolean% intrinsic object and the initial value of the Boolean property of the global object. When Boolean is called as a function rather than as a constructor, it performs a type conversion. However, if the this value passed in the call is an Object with an uninitialised [[BooleanData]] internal data property, it initializes the this value using the argument value. This permits Boolean to be used both to perform type conversion and to perform constructor instance initialization.

The Boolean constructor is designed to be subclassable. It may be used as the value of an extends clause of a class declaration. Subclass constructors that intended to inherit the specified Boolean behaviour must include a super call to the Boolean constructor to initialise the [[BooleanData]] state of subclass instances.

19.3.1.1 Boolean (value)

When Boolean is called with argument value, the following steps are taken:

1. Let O be the this value.
2. Let b be ToBoolean(value).
3. If `Type(O)` is Object and `O` has a `[[BooleanData]]` internal data property and the value of `[[BooleanData]]` is `undefined`, then
   a. Set the value of `O`'s `[[BooleanData]]` internal data property to `b`.
   b. Return `O`.
4. Return `b`.

19.3.1.2 new Boolean (... argumentsList)

Boolean called as part of a new expression, it initialises a newly created object:

1. Let `F` be the Boolean function object on which the `new` operator was applied.
2. Let `argumentsList` be the `argumentsList` argument of the `[[Construct]]` internal method that was invoked by the `new` operator.
3. Return the result of `OrdinaryConstruct(F, argumentsList)`.

If Boolean is implemented as an ordinary function object, its `[[Construct]]` internal method will perform the above steps.

19.3.2 Properties of the Boolean Constructor

The value of the `[[Prototype]]` internal data property of the Boolean constructor is the Function prototype object (19.2.3).

Besides the `length` property (whose value is `1`), the Boolean constructor has the following property:

19.3.2.1 Boolean.prototype

The initial value of `Boolean.prototype` is the Boolean prototype object (19.3.3).

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

19.3.2.2 Boolean @@create ()

The `@@create` method of an object `F` performs the following steps:

1. Let `F` be the `this` value.
2. Let `obj` be the result of calling `OrdinaryCreateFromConstructor(F, "%BooleanPrototype%", [[BooleanData]])`.
3. Return `obj`.

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

NOTE `[[BooleanData]]` is initially assigned the value `undefined` as a flag to indicate that the instance has not yet been initialised by the Boolean constructor. This flag value is never directly exposed to ECMAScript code; hence implementors may choose to encode the flag in some other manner.

19.3.3 Properties of the Boolean Prototype Object

The Boolean prototype object is an ordinary object. It is not a Boolean instance and does not have a `[[BooleanData]]` internal data property.

The value of the `[[Prototype]]` internal data property of the Boolean prototype object is the standard built-in `Object` prototype object (19.1.4).

The abstract operation `thisBooleanValue(value)` performs the following steps:

1. If `Type(value)` is Boolean, return `value`.
2. If `Type(value)` is Object and `value` has a `[[BooleanData]]` internal data property, then
   a. Let `b` be the value of `value`'s `[[BooleanData]]` internal data property.
   b. If `b` is not `undefined`, then return `b`.  

3. Throw a **TypeError** exception.

### 19.3.3.1 Boolean.prototype.constructor

The initial value of `Boolean.prototype.constructor` is the built-in `Boolean` constructor.

### 19.3.3.2 Boolean.prototype.toString ( )

The following steps are taken:

1. Let `b` be thisBooleanValue(this value).
2. ReturnIfAbrupt(`b`).
3. If `b` is `true`, then return "true"; else return "false".

### 19.3.3.3 Boolean.prototype.valueOf ( )

The following steps are taken:

1. Return thisBooleanValue(this value).

### 19.3.4 Properties of Boolean Instances

Boolean instances are ordinary objects that inherit properties from the Boolean prototype object. Boolean instances have a `[[BooleanData]]` internal data property. The `[[BooleanData]]` internal data property is the Boolean value represented by this Boolean object.

### 19.4 Error Objects

Instances of Error objects are thrown as exceptions when runtime errors occur. The Error objects may also serve as base objects for user-defined exception classes.

#### 19.4.1 The Error Constructor

The `Error` constructor is the `%Error%` intrinsic object and the initial value of the `Error` property of the global object. When `Error` is called as a function rather than as a constructor, it creates and initialises a new Error object. Thus the function call `Error(…)` is equivalent to the object creation expression `new Error(…)` with the same arguments. However, if the `this` value value passed in the call is an Object with an uninitialised `[[ErrorData]]` internal data property, it initialises the `this` value using the argument value rather than creating a new object. This permits `Error` to be used both as factory method and to perform constructor instance initialization.

The `Error` constructor is designed to be subclassable. It may be used as the value of an `extends` clause of a class declaration. Subclass constructors that intended to inherit the specified `Error` behaviour should include a `super` call to the `Error` constructor to initialise subclass instances.

#### 19.4.1.1 Error (message)

When the `Error` function is called with argument `message` the following steps are taken:

1. Let `func` be this `Error` function object.
2. Let `O` be the `this` value.
3. If `Type(O)` is not Object or `Type(O)` is Object and `O` does not have an `[[ErrorData]]` internal data property or `Type(O)` is Object and `O` has an `[[ErrorData]]` internal data property and the value of `[[ErrorData]]` is not `undefined`, then:
   a. Let `O` be the result of calling `OrdinaryCreateFromConstructor(func, "%ErrorPrototype\%").`.
   b. ReturnIfAbrupt(`O`).
4. Assert: `Type(O)` is Object.
5. Set the value of \( O \)'s [[ErrorData]] internal data property to any value other than `undefined`.

6. If `message` is not `undefined`, then
   a. Let `msg` be `ToString(message)`.
   b. ReturnIfAbrupt(`msg`).
   c. Let `msgDesc` be the Property Descriptor {[[Value]]: `msg`, [[Writable]]: `true`, [[Enumerable]]: `false`, [[Configurable]]: `true`}.
   d. Let `status` be the result of DefinePropertyOrThrow(`O`, `message`, `msgDesc`).
   e. ReturnIfAbrupt(`status`).

7. Return `O`.

19.4.1.2 `new` Error(... `argumentsList`)

When `Error` called as part of a new expression with argument list `argumentsList` it performs the following steps:

1. Let `F` be the `Error` function object on which the `new` operator was applied.
2. Let `argumentsList` be the `argumentsList` argument of the [[Construct]] internal method that was invoked by the `new` operator.
3. Return the result of OrdinaryConstruct(`F`, `argumentsList`).

If `Error` is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.

19.4.2 Properties of the Error Constructor

The value of the [[Prototype]] internal data property of the Error constructor is the Function prototype object (19.2.3).

Besides the internal properties and the `length` property (whose value is 1), the Error constructor has the following property:

19.4.2.1 `Error.prototype`

The initial value of `Error.prototype` is the Error prototype object (19.4.3).

This property has the attributes { [[Writable]]: `false`, [[Enumerable]]: `false`, [[Configurable]]: `false` }.

19.4.2.2 `Error @@create` ()

The `@@create` method of an object `F` performs the following steps:

1. Let `F` be the `this` value.
2. Let `obj` be the result of calling OrdinaryCreateFromConstructor(`F`, `%ErrorPrototype%`, ( [[ErrorData]] )).  
3. Return `obj`.

This property has the attributes { [[Writable]]: `false`, [[Enumerable]]: `false`, [[Configurable]]: `true` }.

**NOTE** `[[ErrorData]]` is initially assigned the value `undefined` as a flag to indicate that the instance has not yet been initialised by the Error constructor. This flag value is never directly exposed to ECMAScript code; hence implementation may choose to encode the flag in some other manner.

19.4.3 Properties of the Error Prototype Object

The Error prototype object is an ordinary object. It is not an Error instance and does not have an [[ErrorData]] internal data property.

The value of the [[Prototype]] internal data property of the Error prototype object is the standard built-in Object prototype object (19.1.4).
19.4.3.1 Error.prototype.constructor

The initial value of Error.prototype.constructor is the built-in Error constructor.

19.4.3.2 Error.prototype.message

The initial value of Error.prototype.message is the empty String.

19.4.3.3 Error.prototype.name

The initial value of Error.prototype.name is "Error".

19.4.3.4 Error.prototype.toString()

The following steps are taken:

1. Let O be the this value.
2. If Type(O) is not Object, throw a TypeError exception.
3. Let name be the result of Get(O, "name").
4. ReturnIfAbrupt(name).
5. If name is undefined, then let name be "Error"; else let name be ToString(name).
6. Let msg be the result of Get(O, "message").
7. ReturnIfAbrupt(msg).
8. If msg is undefined, then let msg be the empty String; else let msg be ToString(msg).
9. If name is the empty String, return msg.
10. If msg is the empty String, return name.
11. Return the result of concatenating name, ":", a single space character, and msg.

19.4.4 Properties of Error Instances

Error instances are ordinary objects that inherit properties from the Error prototype object and have a [[ErrorData]] internal data property whose initial value is undefined. The only specified uses of [[ErrorData]] is to flag whether or not an Error instance has been initialised by the Error constructor and to identify them as Error objects within Object.prototype.toString.

19.4.5 Native Error Types Used in This Standard

A new instance of one of the NativeError objects below is thrown when a runtime error is detected. All of these objects share the same structure, as described in 19.4.6.

19.4.5.1 EvalError

This exception is not currently used within this specification. This object remains for compatibility with previous editions of this specification.

19.4.5.2 RangeError

Indicates a value that is not in the set or range of allowable values. See 15.4.2.2, 15.4.5.1, 15.7.4.2, 15.7.4.5, 15.7.4.6, 15.7.4.7, and 15.9.5.43.

19.4.5.3 ReferenceError

Indicate that an invalid reference value has been detected. See 8.9.1, 8.9.2, 10.2.1, 10.2.1.1.4, 10.2.1.2.4, and 11.13.1.
19.4.5.4 SyntaxError

Indicates that a parsing error has occurred. See 11.1.5, 11.3.1, 11.3.2, 11.4.1, 11.4.4, 11.4.5, 11.13.1, 11.13.2, 12.2.1, 12.10.1, 12.14.1, 13.1, 15.1.2.1, 15.3.2.1, 15.10.2.2, 15.10.2.9, 15.10.2.15, 15.10.4.1, and 15.12.2.

19.4.5.5 TypeError

Indicates the actual type of an operand is different than the expected type. See 8.6.2, 8.9.2, 8.10.5, 8.12.5, 8.12.7, 8.12.8, 8.12.9, 9.9, 9.10, 10.2.1, 10.2.1.1.3, 10.6, 11.2.2, 11.2.3, 11.4.1, 11.8.6, 11.8.7, 11.3.1, 13.2, 13.2.3, 15, 15.2.3.2, 15.2.3.3, 15.2.3.4, 15.2.3.5, 15.2.3.6, 15.2.3.7, 15.2.3.8, 15.2.3.10, 15.2.3.11, 15.2.3.13, 15.2.3.14, 15.2.3.15, 15.3.2.1, 15.3.3.3, 15.3.3.4, 15.3.3.5, 15.3.3.6, 15.3.3.7, 15.3.4.3, 15.3.4.4, 15.4.3.1, 15.4.3.11, 15.4.3.16, 15.4.3.17, 15.4.3.18, 15.4.3.19, 15.4.3.20, 15.4.3.21, 15.4.3.22, 15.4.5.1, 15.5.4.1, 15.6.4.2, 15.6.4.3, 15.7.4, 15.7.4.2, 15.7.4.4, 15.9.5, 15.9.5.44, 15.10.4.1, 15.10.6, 15.11.4.4 and 15.12.3.

19.4.5.6 URIError

Indicates that one of the global URI handling functions was used in a way that is incompatible with its definition. See 15.1.3.

19.4.6 NativeError Object Structure

When an ECMAScript implementation detects a runtime error, it throws a new instance of one of the NativeError objects defined in 19.4.5. Each of these objects has the structure described below, differing only in the name used as the constructor name instead of NativeError, in the name property of the prototype object, and in the implementation-defined message property of the prototype object.

For each error object, references to NativeError in the definition should be replaced with the appropriate error object name from 19.4.5.

19.4.6.1 NativeError Constructors

When a NativeError constructor is called as a function rather than as a constructor, it creates and initialises a new object. A call of the object as a function is equivalent to calling it as a constructor with the same arguments. However, if the this value passed in the call is an Object with an uninitialised [[ErrorData]] internal data property, it initialises the this value using the argument value. This permits a NativeError to be used both as factory method and to perform constructor instance initialization.

The NativeError constructor is designed to be subclassable. It may be used as the value of an extends clause of a class declaration. Subclass constructors that intended to inherit the specified NativeError behaviour should include a super call to the NativeError constructor to initialise subclass instances.

19.4.6.1.1 NativeError (message)

When a NativeError function is called with argument message the following steps are taken:

1. Let func be this NativeError function object.
2. Let O be the this value.
3. If Type(O) is not Object or Type(O) is Object and O does not have an [[ErrorData]] internal data property or Type(O) is Object and O has an [[ErrorData]] internal data property and the value of [[ErrorData]] is not undefined, then
   a. Let O be the result of calling OrdinaryCreateFromConstructor(func, "%NativeErrorPrototype\%", ( [[ErrorData]] ) )
   b. ReturnIfAbrupt(O).
4. Assert: Type(O) is Object.
5. Set the value of O’s [[ErrorData]] internal data property to any value other than undefined.
6. If message is not undefined, then
   a. Let msg be ToString(message).

Commented [AWB10121]: Sectin references have not yet been updated to reflect ES6

Commented [AWB14122]: This then clause corresponds to the ‘called as a function’ case the ES5 spec.
b. Let msgDesc be the Property Descriptor {
[[Value]]: msg, 
[[Writable]]: true, 
[[Enumerable]]: false,
[[Configurable]]: true}.  
c. Let status be the result of DefinePropertyOrThrow(O, "message", msgDesc).  
d. ReturnIfAbrupt(status).  

7. Return O.  

The actual value of the string passed in step 3.a is either 
"%EvalErrorPrototype%", 
"%RangeErrorPrototype%", "%ReferenceErrorPrototype%", "%SyntaxErrorPrototype%", 
"%TypeErrorPrototype%", or "%URIErrorPrototype%" corresponding to which NativeError constructor is being defined.  
19.4.6.1.2 new NativeError (... argumentsList )  

When a NativeError constructor is called as part of a new expression with argument list argumentsList it performs the following steps:  
1. Let F be this NativeError function object on which the new operator was applied.  
2. Let argumentsList be the argumentsList argument of the [[Construct]] internal method that was invoked by the new operator.  
3. Return the result of OrdinaryConstruct (F, argumentsList).  

If a NativeError constructor is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.  
19.4.6.2 Properties of the NativeError Constructors  
The value of the [[Prototype]] internal data property of a NativeError constructor is the Error constructor object (19.4.1).  

Besides the length property (whose value is 1), each NativeError constructor has the following property:  
19.4.6.2.1 NativeError.prototype  
The initial value of NativeError.prototype is a NativeError prototype object (19.4.6.3). Each NativeError constructor has a separate prototype object.  

This property has the attributes ( [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false ).  
19.4.6.2.2 NativeError [ @@create ] ( )  
The @@create method of an object F performs the following steps:  
1. Let F be the this value.  
2. Let obj be the result of calling OrdinaryCreateFromConstructor(F, NativeErrorPrototype, ( [[ErrorData]])).  
3. Return obj.  

The actual value passed as NativeErrorPrototype in step 2 is either 
"%EvalErrorPrototype%", 
"%RangeErrorPrototype%", "%ReferenceErrorPrototype%", "%SyntaxErrorPrototype%", 
"%TypeErrorPrototype%", or "%URIErrorPrototype%" corresponding to which NativeError constructor is being defined.  

This property has the attributes ( [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true ).  

NOTE [[ErrorData]] is initially assigned the value undefined as a flag to indicate that the instance has not yet been initialised by the Boolean constructor. This flag value is never directly exposed to ECMAScript code; hence implementation may choose to encode the flag in some other manner.
19.4.6.3 Properties of the NativeError Prototype Objects

Each NativeError prototype object is an ordinary object. It is not an Error instance and does not have an [[ErrorData]] internal data property.

The value of the [[Prototype]] internal data property of each NativeError prototype object is the standard built-in Error prototype object (19.4.3).

19.4.6.3.1 NativeError.prototype.constructor

The initial value of the constructor property of the prototype for a given NativeError constructor is the NativeError constructor function itself (19.4.6.1).

19.4.6.3.2 NativeError.prototype.message

The initial value of the message property of the prototype for a given NativeError constructor is the empty String.

19.4.6.3.3 NativeError.prototype.name

The initial value of the name property of the prototype for a given NativeError constructor is a string consisting of the name of the constructor (the name used instead of NativeError).

19.4.6.4 Properties of NativeError Instances

NativeError instances are ordinary objects that inherit properties from their NativeError prototype object and have a [[ErrorData]] internal data property whose initial value is undefined. The only specified use of [[ErrorData]] is to flag whether or not an Error or NativeError instance has been initialised by its constructor.

20 Numbers and Dates

20.1 Number Objects

20.1.1 The Number Constructor

The Number constructor is the %Number% intrinsic object and the initial value of the Number property of the global object. When Number is called as a function rather than as a constructor, it performs a type conversion. However, if the this value passed in the call is an Object with an uninitialised [[NumberData]] internal data property, it initialises the this value using the argument value. This permits Number to be used both to perform type conversion and to perform constructor instance initialization.

The Number constructor is designed to be subclassable. It may be used as the value of an extends clause of a class declaration. Subclass constructors that intended to inherit the specified Number behaviour must include a super call to the Number constructor to initialise the [[NumberData]] state of subclass instances.

20.1.1.1 Number ( [ value ] )

When Number is called with argument number, the following steps are taken:

1. Let O be the this value.
2. If no arguments were passed to this function invocation, then let n be +0.
3. Else, let n be ToNumber(value).
4. ReturnIfAbrupt(n).
5. If Type(O) is Object and O has a [[NumberData]] internal data property and the value of [[NumberData]] is undefined, then
   a. Set the value of O’s [[NumberData]] internal data property to n.
   b. Return O.
6. Return n.
20.1.1.2 new Number (...argumentsList)

new Number called as part of a new expression with argument list argumentsList performs the following steps:

1. Let F be the Number function object on which the new operator was applied.
2. Let argumentsList be the argumentsList argument of the [[Construct]] internal method that was invoked by the new operator.
3. Return the result of OrdinaryConstruct (F, argumentsList).

If Number is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.

20.1.2 Properties of the Number Constructor

The value of the [[Prototype]] internal data property of the Number constructor is the Function prototype object (19.2.3).

Besides the length property (whose value is 1), the Number constructor has the following properties:

20.1.2.1 Number.EPSILON

The value of Number.EPSILON is the difference between 1 and the smallest value greater than 1 that is representable as a Number value, which is approximately 2.22044604925031308472633361816 x 10^-16.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.1.2.2 Number.isFinite (number)

When the Number.isFinite is called with one argument number, the following steps are taken:

1. If Type(number) is not Number, return false.
2. If number is NaN, +oo, or -oo, return false.
3. Otherwise, return true.

20.1.2.3 Number.isInteger (number)

When the Number.isInteger is called with one argument number, the following steps are taken:

1. If Type(number) is not Number, return false.
2. If number is NaN, +oo, or -oo, return false.
3. Let integer be ToInteger(number).
4. If integer is not equal to number, return false.
5. Otherwise, return true.

20.1.2.4 Number.isNaN (number)

When the Number.isNaN is called with one argument number, the following steps are taken:

1. If Type(number) is not Number, return false.
2. If number is NaN, return true.
3. Otherwise, return false.

NOTE This function differs from the global isNaN function (18.2.3) is that it does not convert its argument to a Number before determining whether it is NaN.

20.1.2.5 Number.isSafeInteger (number)

When the Number.isSafeInteger is called with one argument number, the following steps are taken:
1. If `Type(number)` is not Number, return false.
2. If number is NaN, +∞, or −∞, return false.
3. Let `integer` be `ToInteger(number)`.
4. If `integer` is not equal to `number`, return false.
5. If `abs(integer) ≤ 2^{53}-1`, then return true.
6. Otherwise, return false.

20.1.2.6 `Number.MAX_SAFE_INTEGER`

The value of `Number.MAX_SAFE_INTEGER` is 9007199254740991 (2^{53}-1).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.1.2.7 `Number.MAX_VALUE`

The value of `Number.MAX_VALUE` is the largest positive finite value of the Number type, which is approximately 1.7976931348623157 × 10^{308}.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.1.2.8 `Number.NaN`

The value of `Number.NaN` is NaN.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.1.2.9 `Number.NEGATIVE_INFINITY`

The value of `Number.NEGATIVE_INFINITY` is −∞.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.1.2.10 `Number.MIN_SAFE_INTEGER`

The value of `Number.MIN_SAFE_INTEGER` is −9007199254740991 (−2^{53}-1).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.1.2.11 `Number.MIN_VALUE`

The value of `Number.MIN_VALUE` is the smallest positive value of the Number type, which is approximately 5 × 10^{-324}.

In the IEEE-754 double precision binary representation, the smallest possible value is a denormalized number. If an implementation does not support denormalized values, the value of `Number.MIN_VALUE` must be the smallest non-zero positive value that can actually be represented by the implementation.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.1.2.12 `Number.parseFloat(string)`

The value of the `Number.parseFloat` data property is the same built-in function object that is the value of the `parseFloat` property of the global object defined in 18.2.4.

20.1.2.13 `Number.parseInt(string, radix)`

The value of the `Number.parseInt` data property is the same built-in function object that is the value of the `parseInt` property of the global object defined in 18.2.1.2.
20.1.2.14 Number.POSITIVE_INFINITY

The value of Number.POSITIVE_INFINITY is +∞.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.1.2.15 Number.prototype

The initial value of Number.prototype is the Number prototype object (20.1.3).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.1.2.16 Number[@@create] ()

The @@create method of an object F performs the following steps:

1. Let F be the this value.
2. Let obj be the result of calling OrdinaryCreateFromConstructor(F, "NumberPrototype", ( [[NumberData]] ).
3. Return obj.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: true, [[Configurable]]: true }.

NOTE [[NumberData]] is initially assigned the value undefined as a flag to indicate that the instance has not yet been initialised by the Number constructor. This flag value is never directly exposed to ECMAScript code; hence implementation may choose to encode the flag in some other manner.

20.1.3 Properties of the Number Prototype Object

The Number prototype object is an ordinary object. It is not a Number instance and does not have a [[NumberData]] internal data property.

The value of the [[Prototype]] internal data property of the Number prototype object is the standard built-in Object prototype object (19.1.4).

Unless explicitly stated otherwise, the methods of the Number prototype object defined below are not generic and the this value passed to them must be either a Number value or an object that has a [[NumberData]] internal data property that has been initialised to a Number value.

The abstract operation thisNumberValue(value) performs the following steps:

1. If Type(value) is Number, return value.
2. If Type(value) is Object and value has a [[NumberData]] internal data property, then
   a. Let n be the value of value's [[NumberData]] internal data property.
   b. If n is not undefined, then return n.
3. Throw a TypeError exception.

The phrase “this Number value” within the specification of a method refers to the result returned by calling the abstract operation thisNumberValue with the this value of the method invocation passed as the argument.

20.1.3.1 Number.prototype.clz ()

When Number.prototype.clz is called with one argument number, the following steps are taken:

1. Let x be thisNumberValue(this value).
2. Let n be ToUint32(x).
3. ReturnIfAbrupt(n).
4. Let p be the number of leading zero bits in the 32-bit binary representation of n.
5. Return p.

Commented [AWB7123]: Added at March 29 TC39 meeting

Commented [AWB7124]: Unsigned seems most general, signed values could be converted in a previous step.
NOTE If $n$ is 0, $p$ will be 32. If the most significant bit of the 32-bit binary encoding of $n$ is 1, $p$ will be 0.

20.1.3.2 Number.prototype.constructor

The initial value of `Number.prototype.constructor` is the built-in `Number` constructor.

20.1.3.3 Number.prototype.toFixed(fractionDigits)

Return a String containing this Number value represented in decimal exponential notation with one digit before the significand's decimal point and `fractionDigits` digits after the significand's decimal point. If `fractionDigits` is `undefined`, include as many significand digits as necessary to uniquely specify the Number (just like in `toString` except that in this case the Number is always output in exponential notation). Specifically, perform the following steps:

1. Let $x$ be thisValue(this value).
2. ReturnIfAbrupt($x$).
3. Let $f$ be `ToInteger(fractionDigits)`.
4. Assert: $f$ is 0, when `fractionDigits` is `undefined`.
5. ReturnIfAbrupt($f$).
6. If $x$ is `NaN`, return the String "NaN".
7. Let $s$ be the empty String.
8. If $x < 0$, then
   a. Let $s$ be "-".
   b. Let $x = -x$.
9. If $x = +\infty$, then
   a. Return the concatenation of the Strings $s$ and "Infinity".
10. If $f < 0$ or $f > 20$, throw a `RangeError` exception.
11. If $x = 0$, then
   a. Let $m$ be the String consisting of $f+1$ occurrences of the code unit 0x0030.
   b. Let $e = 0$.
12. Else $x \neq 0$,
   a. If `fractionDigits` is not `undefined`, then
      i. Let $e$ and $n$ be integers such that $10^f \leq n < 10^{f+1}$ and for which the exact mathematical value of $n \times 10^{e-f} \times x$ is as close to zero as possible. If there are two such sets of $e$ and $n$, pick the $e$ and $n$ for which $n \times 10^{e-f}$ is larger.
   b. Else `fractionDigits` is `undefined`,
      i. Let $e$, $n$, and $f$ be integers such that $f \geq 0$, $10^f \leq n < 10^{f+1}$, the number value for $n \times 10^{e-f}$ is $x$, and $f$ is as small as possible. Note that the decimal representation of $n$ has $f+1$ digits, $n$ is not divisible by 10, and the least significant digit of $n$ is not necessarily uniquely determined by these criteria.
   c. Let $m$ be the String consisting of the digits of the decimal representation of $n$ (in order, with no leading zeroes).
13. If $e \neq 0$, then
   a. Let $a$ be the first element of $m$, and let $b$ be the remaining $f$ elements of $m$.
   b. Let $m$ be the concatenation of the three Strings $a$, ", ", and $b$.
14. If $e = 0$, then
   a. Let $c = "+"$.
   b. Let $d = "0"$.
15. Else
   a. If $e > 0$, then let $c = "+"$.
   b. Else $e \leq 0$,
      i. Let $c = "-"$.
      ii. Let $e = -e$.
   c. Let $d$ be the String consisting of the digits of the decimal representation of $e$ (in order, with no leading zeroes).
16. Let $m$ be the concatenation of the four Strings $m$, "e", $c$, and $d$.
17. Return the concatenation of the Strings $s$ and $m$.

© Ecma International 2013
The `length` property of the `toExponential` method is 1.

If the `toExponential` method is called with more than one argument, then the behaviour is undefined (see clause 15).

An implementation is permitted to extend the behaviour of `toExponential` for values of `fractionDigits` less than 0 or greater than 20. In this case `toExponential` would not necessarily throw `RangeError` for such values.

NOTE For implementations that provide more accurate conversions than required by the rules above, it is recommended that the following alternative version of step 9.b.i be used as a guideline:

i. Let e, n, and f be integers such that \( f \geq 0, 10^f \leq n < 10^{f+1} \), the number value for \( n \times 10^{-f} \) is x, and f is as small as possible. If there are multiple possibilities for n, choose the value of n for which \( n \times 10^{-f} \) is closest in value to x. If there are two such possible values of n, choose the one that is even.

20.1.3.4 Number.prototype.toFixed (fractionDigits)

Note `toFixed` returns a String containing this Number value represented in decimal fixed-point notation with `fractionDigits` digits after the decimal point. If `fractionDigits` is `undefined`, 0 is assumed.

The following steps are performed:

1. Let x be thisNumberValue(`this` value).
2. ReturnIfAbrupt(x).
3. Let f be ToInteger(fractionDigits). (If fractionDigits is undefined, this step produces the value 0).
4. ReturnIfAbrupt(f).
5. If f < 0 or f > 20, throw a `RangeError` exception.
6. If x is NaN, return the String “NaN”.
7. Let s be the empty String.
8. If x < 0, then
   a. Let x be “-”.
   b. Let x = –x.
9. If x ≥ 10^{21}, then
   a. Let m = ToString(x).
10. Else x < 10^{21},
   a. Let n be an integer for which the exact mathematical value of \( n + 10^f \) – x is as close to zero as possible. If there are two such n, pick the larger n.
   b. If n = 0, let m be the String “0”. Otherwise, let m be the String consisting of the digits of the decimal representation of n (in order, with no leading zeroes).
   c. If f ≠ 0, then
      i. Let k be the number of elements in m.
      ii. If k ≤ f, then
          1. Let z be the string consisting of \( f+1-k \) occurrences of the code unit 0x0030.
          2. Let m be the concatenation of Strings z and m.
          3. Let k = f + 1.
      iii. Let a be the first \( k-f \) elements of m, and let b be the remaining f elements of m.
      iv. Let m be the concatenation of the three Strings a, “.”, and b.
11. Return the concatenation of the Strings s and m.

The `length` property of the `toFixed` method is 1.

If the `toFixed` method is called with more than one argument, then the behaviour is undefined (see clause 15).

An implementation is permitted to extend the behaviour of `toFixed` for values of `fractionDigits` less than 0 or greater than 20. In this case `toFixed` would not necessarily throw `RangeError` for such values.
NOTE: The output of `toFixed` may be more precise than `toString` for some values because `toString` only prints enough significant digits to distinguish the number from adjacent number values. For example, `(1000000000000000128).toFixed(0)` returns "1000000000000000100", while `(1000000000000000128).toFixed(0)` returns "10000000000000000128".

20.1.3.5 Number.prototype.toLocaleString()

Produces a String value that represents this Number value formatted according to the conventions of the host environment's current locale. This function is implementation-dependent, and it is permissible, but not encouraged, for it to return the same thing as `toString`.

NOTE: The first parameter to this function is likely to be used in a future version of this standard; it is recommended that implementations do not use this parameter position for anything else.

20.1.3.6 Number.prototype.toPrecision (precision)

Return a String containing this Number value represented either in decimal exponential notation with one digit before the significand's decimal point and `precision`–1 digits after the significand's decimal point or in decimal fixed notation with `precision` significant digits. If `precision` is `undefined`, call `toString` (7.1.8) instead. Specifically, perform the following steps:

1. Let x be thisNumberValue(this value).
2. ReturnIfAbrupt(x).
3. If `precision` is `undefined`, return ToString(x).
4. Let p be ToInteger(precision).
5. ReturnIfAbrupt(p).
6. If x is NaN, return the String "NaN".
7. Let s be the empty String.
8. If x < 0, then
   a. Let x = –x.
9. If x is +∞, then
   a. Return the concatenation of the Strings s and "Infinity".
10. If p < 1 or p > 21, throw a RangeError exception.
11. If x = 0, then
   a. Let m be the String consisting of p occurrences of the code unit 0x0030 (the Unicode character '0').
   b. Let e = 0.
12. Else x ≠ 0,
   a. Let e and n be integers such that $10^p - 1 \leq n < 10^p$ and for which the exact mathematical value of $n \times 10^{e+1} - x$ is as close to zero as possible. If there are two such sets of e and n, pick the e and n for which $n \times 10^{e+1}$ is larger.
   b. Let m be the String consisting of the digits of the decimal representation of n (in order, with no leading zeroes).
   c. If $e < -6$ or $e \geq p$, then
      i. Let a be the first element of m, and let b be the remaining p–1 elements of m.
      ii. Let m be the concatenation of the three Strings a, " ", and b.
      iii. If e = 0, then
          1. Let c = "+" and d = "0".
      iv. Else e ≠ 0,
          1. If e > 0, then
             a. Let c = "+".
          2. Else e < 0,
             a. Let c = "-".
             b. Let e = –e.
          3. Let d be the String consisting of the digits of the decimal representation of e (in order, with no leading zeroes).
      v. Let m be the concatenation of the five Strings x, m, "e", c, and d.
13. If e = p–1, then return the concatenation of the Strings s and m.
14. If e ≥ 0, then
a. Let \( m \) be the concatenation of the first \( e+1 \) elements of \( m \), the code unit 0x002E (Unicode character "."), and the remaining \( p-(e+1) \) elements of \( m \).

15. Else \( e < 0 \),
   a. Let \( m \) be the concatenation of the String "0."\( -(e+1) \) occurrences of code unit 0x0030 (the Unicode character '0'), and the String \( m \).

16. Return the concatenation of the Strings \( s \) and \( m \).

The \texttt{length} property of the \texttt{toFixed} method is 1.

If the \texttt{toFixed} method is called with more than one argument, then the behaviour is undefined (see clause 15).

An implementation is permitted to extend the behaviour of \texttt{toFixed} for values of \texttt{precision} less than 1 or greater than 21. In this case \texttt{toFixed} would not necessarily throw \texttt{RangeError} for such values.

20.1.3.7 \texttt{Number.prototype.toPrecision ([ radix ])}

The optional \texttt{radix} should be an integer value in the inclusive range 2 to 36. If \texttt{radix} not present or is \texttt{undefined} the Number 10 is used as the value of \texttt{radix}. If \texttt{ToInteger(radix)} is the Number 10 then this Number value is given as an argument to the \texttt{toString} abstract operation; the resulting String value is returned.

If \texttt{ToInteger(radix)} is not an integer between 2 and 36 inclusive throw a \texttt{RangeError} exception. If \texttt{ToInteger(radix)} is an integer from 2 to 36, but not 10, the result is a String representation of this Number value using the specified radix. Letters \texttt{a}-\texttt{z} are used for digits with values 10 through 35. The precise algorithm is implementation-dependent if the radix is not 10, however the algorithm should be a generalisation of that specified in 7.1.8.1.

The \texttt{toString} function is not generic; it throws a \texttt{TypeError} exception if its \texttt{this} value is not a Number or a Number object. Therefore, it cannot be transferred to other kinds of objects for use as a method.

20.1.3.8 \texttt{Number.prototype.valueOf ()}

1. Let \( x \) be this Number Value (this value).
2. Return \( x \).

20.1.4 Properties of Number Instances

Number instances are ordinary objects that inherit properties from the Number prototype object. Number instances also have a [[NumberData]] internal data property. The [[NumberData]] internal data property is the Number value represented by this Number object.

20.2 The Math Object

The Math object is a single ordinary object.

The value of the [[Prototype]] internal data property of the Math object is the standard built-in Object prototype object (19.1.4). The Math object has a [[MathTag]] internal data property whose value is \texttt{true}.

The Math is not a function object. It does not have a [[Construct]] internal method; it is not possible to use the Math object as a constructor with the \texttt{new} operator. The Math object also does not have a [[Call]] internal method; it is not possible to invoke the Math object as a function.

NOTE In this specification, the phrase "the Number value for \( x \)" has a technical meaning defined in 6.1.5.

20.2.1 Value Properties of the Math Object

20.2.1.1 \texttt{Math.E}

The Number value for \( e \), the base of the natural logarithms, which is approximately 2.7182818284590452354.
This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.2.1.2 Math.LN10

The Number value for the natural logarithm of 10, which is approximately 2.302585092994046.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.2.1.3 Math.LOG10E

The Number value for the base-10 logarithm of e, the base of the natural logarithms; this value is approximately 0.4342944819032518.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

NOTE The value of Math.LOG10E is approximately the reciprocal of the value of Math.LN10.

20.2.1.4 Math.LN2

The Number value for the natural logarithm of 2, which is approximately 0.6931471805599453.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.2.1.5 Math.LOG2E

The Number value for the base-2 logarithm of e, the base of the natural logarithms; this value is approximately 1.4426950408889634.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

NOTE The value of Math.LOG2E is approximately the reciprocal of the value of Math.LN2.

20.2.1.6 Math.PI

The Number value for π, the ratio of the circumference of a circle to its diameter, which is approximately 3.1415926535897932.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.2.1.7 Math.SQRT1_2

The Number value for the square root of ½, which is approximately 0.7071067811865476.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

NOTE The value of Math.SQRT1_2 is approximately the reciprocal of the value of Math.SQRT2.

20.2.1.8 Math.SQRT2

The Number value for the square root of 2, which is approximately 1.4142135623730951.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

20.2.2 Function Properties of the Math Object

Each of the following Math object functions applies the ToNumber abstract operation to each of its arguments (in left-to-right order if there is more than one); if ToNumber returns an abrupt completion, that completion record is immediately returned. Otherwise, the function performs a computation on the resulting Number value(s).
In the function descriptions below, the symbols NaN, −0, +0, −∞ and +∞ refer to the Number values described in 6.1.5.

NOTE The behaviour of the functions acos, acosh, asin, asinh, atan, atan2, cbrt, cos, cosh, exp, hypot, log, log1p, log2, log10, pow, sin, sinh, sqrt, tan, and tanh is not precisely specified here except to require specific results for certain argument values that represent boundary cases of interest. For other argument values, these functions are intended to compute approximations to the results of familiar mathematical functions, but some latitude is allowed in the choice of approximation algorithms. The general intent is that an implementer should be able to use the same mathematical library for ECMAScript on a given hardware platform that is available to C programmers on that platform.

Although the choice of algorithms is left to the implementation, it is recommended (but not specified by this standard) that implementations use the approximation algorithms for IEEE 754 arithmetic contained in fdlibm, the freely distributable mathematical library from Sun Microsystems (http://www.netlib.org/fdlibm).

20.2.2.1 Math.abs(x)
Returns the absolute value of x; the result has the same magnitude as x but has positive sign.
- If x is NaN, the result is NaN.
- If x is −0, the result is +0.
- If x is −∞, the result is +∞.

20.2.2.2 Math.acos(x)
Returns an implementation-dependent approximation to the arc cosine of x. The result is expressed in radians and ranges from 0 to +π.
- If x is NaN, the result is NaN.
- If x is greater than 1, the result is NaN.
- If x is less than −1, the result is NaN.
- If x is exactly 1, the result is +0.

20.2.2.3 Math.acosh(x)
Returns an implementation-dependent approximation to the inverse hyperbolic cosine of x.
- If x is NaN, the result is NaN.
- If x is less than 1, the result is NaN.
- If x is exactly 1, the result is +0.
- If x is +∞, the result is +∞.

20.2.2.4 Math.asin(x)
Returns an implementation-dependent approximation to the arc sine of x. The result is expressed in radians and ranges from −π/2 to +π/2.
- If x is NaN, the result is NaN.
- If x is greater than 1, the result is NaN.
- If x is less than −1, the result is NaN.
- If x is +0, the result is +0.
- If x is −0, the result is −0.

20.2.2.5 Math.asinh(x)
Returns an implementation-dependent approximation to the inverse hyperbolic sine of x.
- If x is NaN, the result is NaN.
20.2.2.6 Math.atan (x)

Returns an implementation-dependent approximation to the arc tangent of x. The result is expressed in radians and ranges from \(-\pi/2\) to \(+\pi/2\).

- If x is +0, the result is +0.
- If x is -0, the result is -0.
- If x is +\(\infty\), the result is +\(\infty\).
- If x is -\(\infty\), the result is -\(\infty\).

20.2.2.7 Math.atanh(x)

Returns an implementation-dependent approximation to the inverse hyperbolic tangent of x.

- If x is NaN, the result is NaN.
- If x is less than -1, the result is NaN.
- If x is greater than 1, the result is NaN.
- If x is -1, the result is -\(\infty\).
- If x is +1, the result is +\(\infty\).
- If x is +0, the result is +0.
- If x is -0, the result is -0.

20.2.2.8 Math.atan2 (y, x)

Returns an implementation-dependent approximation to the arc tangent of the quotient \(y/x\) of the arguments \(y\) and \(x\), where the signs of \(y\) and \(x\) are used to determine the quadrant of the result. Note that it is intentional and traditional for the two-argument arc tangent function that the argument named \(y\) be first and the argument named \(x\) be second. The result is expressed in radians and ranges from \(-\pi\) to \(+\pi\).

- If either \(x\) or \(y\) is NaN, the result is NaN.
- If \(y\) is +0 and \(x\) is +0, the result is an implementation-dependent approximation to +\(\pi/2\).
- If \(y\) is +0 and \(x\) is -0, the result is an implementation-dependent approximation to -\(\pi/2\).
- If \(y\) is +0 and \(x\) is +0, the result is +0.
- If \(y\) is +0 and \(x\) is -0, the result is +0.
- If \(y\) is +0 and \(x\) is -0, the result is +0.
- If \(y\) is +0 and \(x\) is +0, the result is +0.
- If \(y\) is -0 and \(x\) is +0, the result is +0.
- If \(y\) is -0 and \(x\) is -0, the result is +0.
- If \(y\) is -0 and \(x\) is +0, the result is -0.
- If \(y\) is -0 and \(x\) is -0, the result is -0.
- If \(y\) is -0 and \(x\) is +0, the result is -0.
- If \(y\) is -0 and \(x\) is -0, the result is -0.
- If \(y\) is -0 and \(x\) is +0, the result is -0.
- If \(y\) is -0 and \(x\) is -0, the result is -0.
- If \(y\) is -0 and \(x\) is +0, the result is -0.
• If $y$ is $-\infty$ and $x$ is $-\infty$, the result is an implementation-dependent approximation to $-3\pi/4$.

20.2.2.9 Math.cbrt($x$)

Returns an implementation-dependent approximation to the cube root of $x$.

• If $x$ is NaN, the result is NaN.
• If $x$ is +0, the result is +0.
• If $x$ is −0, the result is −0.
• If $x$ is +\(\infty\), the result is +\(\infty\).
• If $x$ is −\(\infty\), the result is −\(\infty\).

20.2.2.10 Math.ceil ($x$)

Returns the smallest (closest to $-\infty$) Number value that is not less than $x$ and is equal to a mathematical integer. If $x$ is already an integer, the result is $x$.

• If $x$ is NaN, the result is NaN.
• If $x$ is +0, the result is +0.
• If $x$ is −0, the result is −0.
• If $x$ is +\(\infty\), the result is +\(\infty\).
• If $x$ is −\(\infty\), the result is −\(\infty\).

The value of Math.ceil($x$) is the same as the value of −Math.floor(−$x$).

20.2.2.11 Math.cos ($x$)

Returns an implementation-dependent approximation to the cosine of $x$. The argument is expressed in radians.

• If $x$ is NaN, the result is NaN.
• If $x$ is +0, the result is 1.
• If $x$ is −0, the result is 1.
• If $x$ is +\(\infty\), the result is NaN.
• If $x$ is −\(\infty\), the result is NaN.

20.2.2.12 Math.cosh($x$)

Returns an implementation-dependent approximation to the hyperbolic cosine of $x$.

• If $x$ is NaN, the result is NaN.
• If $x$ is +0, the result is 1.
• If $x$ is −0, the result is 1.
• If $x$ is +\(\infty\), the result is +\(\infty\).
• If $x$ is −\(\infty\), the result is +\(\infty\).

NOTE The value of cosh($x$) is the same as \((\exp(x) + \exp(−x))/2\).

20.2.2.13 Math.exp ($x$)

Returns an implementation-dependent approximation to the exponential function of $x$ (\(e\) raised to the power of $x$, where \(e\) is the base of the natural logarithms).

• If $x$ is NaN, the result is NaN.
• If $x$ is +0, the result is 1.
• If $x$ is −0, the result is 1.
• If $x$ is +\(\infty\), the result is +\(\infty\).
• If \( x \) is \(-\infty\), the result is +0.

20.2.2.14 Math.expm1 (\( x \))

Returns an implementation-dependent approximation to subtracting 1 from the exponential function of \( x \) (\( e \) raised to the power of \( x \), where \( e \) is the base of the natural logarithms). The result is computed in a way that is accurate even when the value of \( x \) is close 0.

• If \( x \) is NaN, the result is NaN.
• If \( x \) is +0, the result is +0.
• If \( x \) is –0, the result is –0.
• If \( x \) is +\( \infty \), the result is +\( \infty \).
• If \( x \) is –\( \infty \), the result is -1.

20.2.2.15 Math.floor (\( x \))

Returns the greatest (closest to \(+\infty\)) Number value that is not greater than \( x \) and is equal to a mathematical integer. If \( x \) is already an integer, the result is \( x \).

• If \( x \) is NaN, the result is NaN.
• If \( x \) is +0, the result is +0.
• If \( x \) is –0, the result is –0.
• If \( x \) is +\( \infty \), the result is +\( \infty \).
• If \( x \) is –\( \infty \), the result is –\( \infty \).
• If \( x \) is greater than 0 but less than 1, the result is +0.

NOTE The value of Math.floor (\( x \)) is the same as the value of –Math.ceil (–\( x \)).

20.2.2.16 Math.hypot (\( value1 \), \( value2 \), \( value3 = 0 \))

Given two or three arguments, hypot returns an implementation-dependent approximation of the square root of the sum of squares of up to three arguments.

• If any argument is +\( \infty \), the result is +\( \infty \).
• If any argument is –\( \infty \), the result is +\( \infty \).
• If no argument is +\( \infty \) or –\( \infty \), and any argument is NaN, the result is NaN.
• If all arguments are either +0 or –0, the result is +0.
• The implementation must avoid underflow.
• The implementation must avoid overflow, where possible.
• The implementation must minimise rounding errors.

The length property of the hypot function is 2.

20.2.2.17 Math.imul (\( x \), \( y \))

When the Math.imul is called with arguments \( x \) and \( y \) the following steps are taken:

1. Let \( a \) be ToUint32 (\( x \)).
2. ReturnIfAbrupt (\( a \)).
3. Let \( b \) be ToUint32 (\( y \)).
4. ReturnIfAbrupt (\( b \)).
5. Let product be \((a \times b) \mod 2^{32}\).
6. If \( \text{product} \geq 2^{31} \), return \( \text{product} – 2^{31} \), otherwise return product.

20.2.2.18 Math.log (\( x \))

• Returns an implementation-dependent approximation to the natural logarithm of \( x \).
• If \( x \) is NaN, the result is NaN.
• If \( x \) is less than 0, the result is NaN.
• If \( x \) is +0 or −0, the result is −∞.
• If \( x \) is 1, the result is +0.
• If \( x \) is +∞, the result is +∞.

20.2.2.19 Math.log1p (x)
Returns an implementation-dependent approximation to the natural logarithm of 1 + \( x \). The result is computed in a way that is accurate even when the value of \( x \) is close to zero.

• If \( x \) is NaN, the result is NaN.
• If \( x \) is less than -1, the result is NaN.
• If \( x \) is -1, the result is −∞.
• If \( x \) is +0, the result is +0.
• If \( x \) is −0, the result is −0.
• If \( x \) is +∞, the result is +∞.

20.2.2.20 Math.log10 (x)
Returns an implementation-dependent approximation to the base 10 logarithm of \( x \).

• If \( x \) is NaN, the result is NaN.
• If \( x \) is less than 0, the result is NaN.
• If \( x \) is +0, the result is −∞.
• If \( x \) is −0, the result is −∞.
• If \( x \) is 1, the result is +0.
• If \( x \) is +∞, the result is +∞.

20.2.2.21 Math.log2 (x)
Returns an implementation-dependent approximation to the base 2 logarithm of \( x \).

• If \( x \) is NaN, the result is NaN.
• If \( x \) is less than 0, the result is NaN.
• If \( x \) is +0, the result is −∞.
• If \( x \) is −0, the result is −∞.
• If \( x \) is 1, the result is +0.
• If \( x \) is +∞, the result is +∞.

20.2.2.22 Math.max ([value1 [, value2 [, … ]]]))
Given zero or more arguments, calls ToNumber on each of the arguments and returns the largest of the resulting values.

• If no arguments are given, the result is −∞.
• If any value is NaN, the result is NaN.
• The comparison of values to determine the largest value is done using the Abstract Relational Comparison algorithm (7.2.8) except that +0 is considered to be larger than −0.

The length property of the max method is 2.
20.2.2.23 Math.min ([value1 [, value2 [, ... ]]]))

Given zero or more arguments, calls ToNumber on each of the arguments and returns the smallest of the resulting values.

- If no arguments are given, the result is +\infty.
- If any value is NaN, the result is NaN.
- The comparison of values to determine the smallest value is done using the Abstract Relational Comparison algorithm (7.2.8) except that +0 is considered to be larger than −0.

The length property of the min method is 2.

20.2.2.24 Math.pow (x, y)

Returns an implementation-dependent approximation to the result of raising \( x \) to the power \( y \).

- If \( y \) is NaN, the result is NaN.
- If \( y \) is +0, the result is 1, even if \( x \) is NaN.
- If \( y \) is −0, the result is 1, even if \( x \) is NaN.
- If \( x \) is NaN and \( y \) is nonzero, the result is NaN.
- If \( \text{abs}(x)>1 \) and \( y \) is +\infty, the result is +\infty.
- If \( \text{abs}(x)<1 \) and \( y \) is +\infty, the result is +0.
- If \( x \) is +0 and \( y \) is an odd integer, the result is +\infty.
- If \( x \) is −0 and \( y \) is an odd integer, the result is −\infty.
- If \( x<0 \) and \( x \) is finite and \( y \) is not an integer, the result is NaN.

20.2.2.25 Math.random ()

Returns a Number value with positive sign, greater than or equal to 0 but less than 1, chosen randomly or pseudo randomly with approximately uniform distribution over that range, using an implementation-dependent algorithm or strategy. This function takes no arguments.

20.2.2.26 Math.round (x)

Returns the Number value that is closest to \( x \) and is equal to a mathematical integer. If two integer Number values are equally close to \( x \), then the result is the Number value that is closer to +\infty. If \( x \) is already an integer, the result is \( x \).

- If \( x \) is NaN, the result is NaN.
- If \( x \) is +0, the result is +0.
- If \( x \) is −0, the result is −0.
- If \( x \) is +\infty, the result is +\infty.
- If \( x \) is −\infty, the result is −\infty.

- If \(x\) is greater than 0 but less than 0.5, the result is \(+0\).
- If \(x\) is less than 0 but greater than or equal to -0.5, the result is \(-0\).

**NOTE 1**  
\(\text{Math.round}(3.5)\) returns 4, but \(\text{Math.round}(-3.5)\) returns 3.

**NOTE 2**  
The value of \(\text{Math.round}(x)\) is the same as the value of \(\text{Math.floor}(x+0.5)\), except when \(x\) is \(+0\) or is less than 0 but greater than or equal to \(-0.5\); for these cases \(\text{Math.round}(x)\) returns \(-0\), but \(\text{Math.floor}(x+0.5)\) returns \(+0\).

20.2.2.27 \text{Math.roundFloat32}(x)

When \(\text{Math.roundFloat32}\) is called with argument \(x\) the following steps are taken:

1. If \(x\) is NaN, return NaN.
2. If \(x\) is one of \(+0\), \(-0\), \(+\infty\), \(-\infty\), then return \(x\).
3. Let \(x_{32}\) be the result of converting \(x\) to a value in IEEE-854-2005 binary32 format using “Round to nearest, ties to even” rounding mode.
4. Let \(x_{64}\) be the ECMAScript Number value corresponding to \(x_{32}\).
5. Return \(x_{64}\).

20.2.2.28 \text{Math.sign}(x)

Returns the sign of the \(x\), indicating whether \(x\) is positive, negative or zero.

- If \(x\) is NaN, the result is NaN.
- If \(x\) is \(-0\), the result is \(-0\).
- If \(x\) is \(+0\), the result is \(+0\).
- If \(x\) is negative and not \(-0\), the result is \(-1\).
- If \(x\) is positive and not \(+0\), the result is \(+1\).

20.2.2.29 \text{Math.sin}(x)

Returns an implementation-dependent approximation to the sine of \(x\). The argument is expressed in radians.

- If \(x\) is NaN, the result is NaN.
- If \(x\) is \(+0\), the result is \(+0\).
- If \(x\) is \(-0\), the result is \(-0\).
- If \(x\) is \(+\infty\) or \(-\infty\), the result is NaN.

20.2.2.30 \text{Math.sinh}(x)

Returns an implementation-dependent approximation to the hyperbolic sine of \(x\).

- If \(x\) is NaN, the result is NaN.
- If \(x\) is \(+0\), the result is \(+0\).
- If \(x\) is \(-0\), the result is \(-0\).
- If \(x\) is \(+\infty\), the result is \(+\infty\).
- If \(x\) is \(-\infty\), the result is \(-\infty\).

**NOTE**  
The value of \(\text{sinh}(x)\) is the same as \((\exp(x) - \exp(-x))/2\).

20.2.2.31 \text{Math.sqrt}(x)

Returns an implementation-dependent approximation to the square root of \(x\).

- If \(x\) is NaN, the result is NaN.
- If \(x\) is less than 0, the result is NaN.
- If \(x\) is \(+0\), the result is \(+0\).
• If \( x \) is \(-0\), the result is \(-0\).
• If \( x \) is \(+\infty\), the result is \(+\infty\).

20.2.2.32 Math.tan \( (x) \)

Returns an implementation-dependent approximation to the tangent of \( x \). The argument is expressed in radians.

• If \( x \) is NaN, the result is NaN.
• If \( x \) is \(-0\), the result is \(-0\).
• If \( x \) is \(+0\), the result is \(+0\).
• If \( x \) is \(-\infty\) or \(+\infty\), the result is NaN.

20.2.2.33 Math.tanh \( (x) \)

Returns an implementation-dependent approximation to the hyperbolic tangent of \( x \).

• If \( x \) is NaN, the result is NaN.
• If \( x \) is \(-0\), the result is \(-0\).
• If \( x \) is \(+0\), the result is \(+0\).
• If \( x \) is \(+\infty\), the result is \(+1\).
• If \( x \) is \(-\infty\), the result is \(-1\).

NOTE The value of \( \tanh(x) \) is the same as \( \frac{\exp(x) - \exp(-x)}{\exp(x) + \exp(-x)} \).

20.2.2.34 Math.trunc \( (x) \)

Returns the integral part of the number \( x \), removing any fractional digits. If \( x \) is already an integer, the result is \( x \).

• If \( x \) is NaN, the result is NaN.
• If \( x \) is \(-0\), the result is \(-0\).
• If \( x \) is \(+0\), the result is \(+0\).
• If \( x \) is \(+\infty\), the result is \(+\infty\).
• If \( x \) is \(-\infty\), the result is \(-\infty\).
• If \( x \) is greater than 0 but less than 1, the result is \(+0\).
• If \( x \) is less than 0 but greater than \(-1\), the result is \(-0\).

20.3 Date Objects

20.3.1 Overview of Date Objects and Definitions of Abstract Operations

The following functions are abstract operations that operate on time values (defined in 20.3.1.1). Note that, in every case, if any argument to one of these functions is NaN, the result will be NaN.

20.3.1.1 Time Values and Time Range

A Date object contains a Number indicating a particular instant in time to within a millisecond. Such a Number is called a time value. A time value may also be NaN, indicating that the Date object does not represent a specific instant of time.

Time is measured in ECMAScript in milliseconds since 01 January, 1970 UTC. In time values leap seconds are ignored. It is assumed that there are exactly 86,400,000 milliseconds per day. ECMAScript Number values can represent all integers from \(-9,007,199,254,740,992\) to \(9,007,199,254,740,992\); this range suffices to measure times to millisecond precision for any instant that is within approximately 285,816 years, either forward or backward, from 01 January, 1970 UTC.
The actual range of times supported by ECMAScript Date objects is slightly smaller: exactly –100,000,000 days to 100,000,000 days measured relative to midnight at the beginning of 01 January, 1970 UTC. This gives a range of 8,640,000,000,000,000 milliseconds to either side of 01 January, 1970 UTC.

The exact moment of midnight at the beginning of 01 January, 1970 UTC is represented by the value +0.

20.3.1.2 Day Number and Time within Day

A given time value \( t \) belongs to day number

\[
\text{Day}(t) = \text{floor}(t / \text{msPerDay})
\]

where the number of milliseconds per day is

\[
\text{msPerDay} = 86400000
\]

The remainder is called the time within the day:

\[
\text{TimeWithinDay}(t) = t \mod \text{msPerDay}
\]

20.3.1.3 Year Number

ECMAScript uses an extrapolated Gregorian system to map a day number to a year number and to determine the month and date within that year. In this system, leap years are precisely those which are (divisible by 4) and ((not divisible by 100) or (divisible by 400)). The number of days in year number \( y \) is therefore defined by

\[
\text{DaysInYear}(y) = \begin{cases} 
365 & \text{if } (y \mod 4) \neq 0 \\
366 & \text{if } (y \mod 4) = 0 \text{ and } (y \mod 100) \neq 0 \\
365 & \text{if } (y \mod 100) = 0 \text{ and } (y \mod 400) \neq 0 \\
366 & \text{if } (y \mod 400) = 0 
\end{cases}
\]

All non-leap years have 365 days with the usual number of days per month and leap years have an extra day in February. The day number of the first day of year \( y \) is given by:

\[
\text{DayFromYear}(y) = 365 \times (y - 1970) + \text{floor}(y - 1969)/4 - \text{floor}(y - 1901)/100 + \text{floor}(y - 1601)/400
\]

The time value of the start of a year is:

\[
\text{TimeFromYear}(y) = \text{msPerDay} \times \text{DayFromYear}(y)
\]

A time value determines a year by:

\[
\text{YearFromTime}(t) = \text{the largest integer } y \text{ (closest to positive infinity) such that } \text{TimeFromYear}(y) \leq t
\]

The leap-year function is 1 for a time within a leap year and otherwise is zero:

\[
\text{InLeapYear}(t) = \begin{cases} 
0 & \text{if } \text{DaysInYear(YearFromTime}(t)) = 365 \\
1 & \text{if } \text{DaysInYear(YearFromTime}(t)) = 366
\end{cases}
\]

20.3.1.4 Month Number

Months are identified by an integer in the range 0 to 11, inclusive. The mapping \( \text{MonthFromTime}() \) from a time value \( t \) to a month number is defined by:

\[
\text{MonthFromTime}(t) = \begin{cases} 
0 & \text{if } 0 \leq \text{DayWithinYear}(t) < 31 \\
1 & \text{if } 31 \leq \text{DayWithinYear}(t) < 90 + \text{InLeapYear}(t) \\
2 & \text{if } 90 + \text{InLeapYear}(t) \leq \text{DayWithinYear}(t) < 120 + \text{InLeapYear}(t) \\
3 & \text{if } 120 + \text{InLeapYear}(t) \leq \text{DayWithinYear}(t) < 151 + \text{InLeapYear}(t) \\
4 & \text{if } 151 + \text{InLeapYear}(t) \leq \text{DayWithinYear}(t) < 181 + \text{InLeapYear}(t) \\
5 & \text{if } 181 + \text{InLeapYear}(t) \leq \text{DayWithinYear}(t) < 212 + \text{InLeapYear}(t) \\
6 & \text{if } 212 + \text{InLeapYear}(t) \leq \text{DayWithinYear}(t) < 243 + \text{InLeapYear}(t) \\
7 & \text{if } 243 + \text{InLeapYear}(t) \leq \text{DayWithinYear}(t) < 273 + \text{InLeapYear}(t) \\
8 & \text{if } 273 + \text{InLeapYear}(t) \leq \text{DayWithinYear}(t) < 304 + \text{InLeapYear}(t) \\
9 & \text{if } 304 + \text{InLeapYear}(t) \leq \text{DayWithinYear}(t) < 334 + \text{InLeapYear}(t) \\
10 & \text{if } 334 + \text{InLeapYear}(t) \leq \text{DayWithinYear}(t) < 365 + \text{InLeapYear}(t)
\end{cases}
\]
20.3.1.5 Date Number

A date number is identified by an integer in the range 1 through 31, inclusive. The mapping DateFromTime(t) from a time value t to a month number is defined by:

\[
\text{DateFromTime}(t) = \begin{cases} 
\text{DayWithinYear}(t) + 1 & \text{if MonthFromTime}(t) = 0 \\
\text{DayWithinYear}(t) - 30 & \text{if MonthFromTime}(t) = 1 \\
\text{DayWithinYear}(t) - 58 - \text{InLeapYear}(t) & \text{if MonthFromTime}(t) = 2 \\
\text{DayWithinYear}(t) - 89 - \text{InLeapYear}(t) & \text{if MonthFromTime}(t) = 3 \\
\text{DayWithinYear}(t) - 119 - \text{InLeapYear}(t) & \text{if MonthFromTime}(t) = 4 \\
\text{DayWithinYear}(t) - 150 - \text{InLeapYear}(t) & \text{if MonthFromTime}(t) = 5 \\
\text{DayWithinYear}(t) - 180 - \text{InLeapYear}(t) & \text{if MonthFromTime}(t) = 6 \\
\text{DayWithinYear}(t) - 211 - \text{InLeapYear}(t) & \text{if MonthFromTime}(t) = 7 \\
\text{DayWithinYear}(t) - 242 - \text{InLeapYear}(t) & \text{if MonthFromTime}(t) = 8 \\
\text{DayWithinYear}(t) - 272 - \text{InLeapYear}(t) & \text{if MonthFromTime}(t) = 9 \\
\text{DayWithinYear}(t) - 303 - \text{InLeapYear}(t) & \text{if MonthFromTime}(t) = 10 \\
\text{DayWithinYear}(t) - 333 - \text{InLeapYear}(t) & \text{if MonthFromTime}(t) = 11 
\end{cases}
\]

20.3.1.6 Week Day

The weekday for a particular time value t is defined as \( \text{WeekDay}(t) = (\text{Day}(t) + 4) \mod 7 \).

A weekday value of 0 specifies Sunday; 1 specifies Monday; 2 specifies Tuesday; 3 specifies Wednesday; 4 specifies Thursday; 5 specifies Friday; and 6 specifies Saturday. Note that \( \text{WeekDay}(0) = 4 \), corresponding to Thursday, 01 January, 1970.

20.3.1.7 Local Time Zone Adjustment

An implementation of ECMAScript is expected to determine the local time zone adjustment. The local time zone adjustment is a value LocalTZA measured in milliseconds which when added to UTC represents the local standard time. Daylight saving time is not reflected by LocalTZA.

NOTE  It is recommended that implementations use the time zone information of the IANA Time Zone Database.

20.3.1.8 Daylight Saving Time Adjustment

An implementation of ECMAScript is expected to make its best effort to determine the local daylight saving time adjustment. An implementation dependent algorithm using best available information on time zones to determine the local daylight saving time adjustment DaylightSavingTA(t), measured in milliseconds.

20.3.1.9 Local Time

Conversion from UTC to local time is defined by

\[
\text{LocalTime}(t) = t + \text{LocalTZA} + \text{DaylightSavingTA}(t)
\]

Conversion from local time to UTC is defined by

\[
\text{UTC}(t) = t - \text{LocalTZA} - \text{DaylightSavingTA}(t - \text{LocalTZA})
\]

Note that \( \text{UTC(LocalTime}(t)) \) is not necessarily always equal to \( t \).
20.3.10 Hours, Minutes, Second, and Milliseconds

The following functions are useful in decomposing time values:

- \( \text{HourFromTime}(t) = \text{floor}(t / \text{msPerHour}) \mod \text{HoursPerDay} \)
- \( \text{MinFromTime}(t) = \text{floor}(t / \text{msPerMinute}) \mod \text{MinutesPerHour} \)
- \( \text{SecFromTime}(t) = \text{floor}(t / \text{msPerSecond}) \mod \text{SecondsPerMinute} \)
- \( \text{msFromTime}(t) = t \mod \text{msPerSecond} \)

where

- \( \text{HoursPerDay} = 24 \)
- \( \text{MinutesPerHour} = 60 \)
- \( \text{SecondsPerMinute} = 60 \)
- \( \text{msPerSecond} = 1000 \)
- \( \text{msPerMinute} = 60000 = \text{msPerSecond} \times \text{SecondsPerMinute} \)
- \( \text{msPerHour} = 360000 = \text{msPerMinute} \times \text{MinutesPerHour} \)

20.3.11 MakeTime (hour, min, sec, ms)

The operator MakeTime calculates a number of milliseconds from its four arguments, which must be ECMAScript Number values. This operator functions as follows:

1. If \( \text{hour} \) is not finite or \( \text{min} \) is not finite or \( \text{sec} \) is not finite or \( \text{ms} \) is not finite, return NaN.
2. Let \( h \) be \( \text{ToInteger}(\text{hour}) \).
3. Let \( m \) be \( \text{ToInteger}(\text{min}) \).
4. Let \( s \) be \( \text{ToInteger}(\text{sec}) \).
5. Let \( \text{milli} \) be \( \text{ToInteger}(\text{ms}) \).
6. Let \( t \) be \( h \times \text{msPerHour} + m \times \text{msPerMinute} + s \times \text{msPerSecond} + \text{milli} \), performing the arithmetic according to IEEE 754 rules (that is, as if using the ECMAScript operators \( \times \) and \( + \)).
7. Return \( t \).

20.3.12 MakeDay (year, month, date)

The operator MakeDay calculates a number of days from its three arguments, which must be ECMAScript Number values. This operator functions as follows:

1. If \( \text{year} \) is not finite or \( \text{month} \) is not finite or \( \text{date} \) is not finite, return NaN.
2. Let \( y \) be \( \text{ToInteger}(\text{year}) \).
3. Let \( m \) be \( \text{ToInteger}(\text{month}) \).
4. Let \( d \) be \( \text{ToInteger}(\text{date}) \).
5. Let \( ym \) be \( y + \text{floor}(m / 12) \).
6. Let \( mn \) be \( m \mod 12 \).
7. Find a value \( t \) such that \( \text{YearFromTime}(t) = ym \) and \( \text{MonthFromTime}(t) = mn \) and \( \text{DateFromTime}(t) = 1 \); but if this is not possible (because some argument is out of range), return NaN.
8. Return \( \text{Day}(t) + d - 1 \).

20.3.13 MakeDate (day, time)

The operator MakeDate calculates a number of milliseconds from its two arguments, which must be ECMAScript Number values. This operator functions as follows:

1. If \( \text{day} \) is not finite or \( \text{time} \) is not finite, return NaN.
2. Return \( \text{day} \times \text{msPerDay} + \text{time} \).
20.3.1.14 TimeClip (time)

The operator TimeClip calculates a number of milliseconds from its argument, which must be an ECMAScript Number value. This operator functions as follows:
1. If time is not finite, return NaN.
2. If abs(time) > 8.64 \times 10^{15}, return NaN.
3. Return ToInteger(time) + (\pm 0). (Adding a positive zero converts \pm 0 to +0.)

NOTE The point of step 3 is that an implementation is permitted a choice of internal representations of time values, for example as a 64-bit signed integer or as a 64-bit floating-point value. Depending on the implementation, this internal representation may or may not distinguish \pm 0 and +0.

20.3.1.15 Date Time String Format

ECMAScript defines a string interchange format for date-times based upon a simplification of the ISO 8601 Extended Format. The format is as follows: YYYY-MM-DDTHH:mm:ss.sssZ

Where the fields are as follows:
- YYYY is the decimal digits of the year 0000 to 9999 in the Gregorian calendar.
- "-" (hyphen) appears literally twice in the string.
- MM is the month of the year from 01 (January) to 12 (December).
- DD is the day of the month from 01 to 31.
- T "T" appears literally in the string, to indicate the beginning of the time element.
- HH is the number of complete hours that have passed since midnight as two decimal digits from 00 to 24.
- ":" (colon) appears literally twice in the string.
- mm is the number of complete minutes since the start of the hour as two decimal digits from 00 to 59.
- ss is the number of complete seconds since the start of the minute as two decimal digits from 00 to 59.
- "." (dot) appears literally in the string.
- sss is the number of complete milliseconds since the start of the second as three decimal digits.
- Z is the time zone offset specified as "Z" (for UTC) or either "+" or "-" followed by a time expression HH:mm

This format includes date-only forms:
- YYYY
- YYYY-MM
- YYYY-MM-DD

It also includes "date-time" forms that consist of one of the above date-only forms immediately followed by one of the following time forms with an optional time zone offset appended:
- THH:mm
- THH:mm:ss
- THH:mm:ss.sss

All numbers must be base 10. If the MM or DD fields are absent "01" is used as the value. If the HH, mm, or ss fields are absent "00" is used as the value and the value of an absent sss field is "000". If the time zone offset is absent, the date-time is interpreted as a local time.

Illegal values (out-of-bounds as well as syntax errors) in a format string means that the format string is not a valid instance of this format.
NOTE 1  As every day both starts and ends with midnight, the two notations 00:00 and 24:00 are available to
distinguish the two midnights that can be associated with one date. This means that the following two notations refer to
exactly the same point in time: 1995-02-04T24:00 and 1995-02-05T00:00

NOTE 2  There exists no international standard that specifies abbreviations for civil time zones like CET, EST, etc. and
sometimes the same abbreviation is even used for two very different time zones. For this reason, ISO 8601 and this
format specifies numeric representations of date and time.

20.3.1.15.1 Extended years

ECMAScript requires the ability to specify 6 digit years (extended years); approximately 285,426 years, either
forward or backward, from 01 January, 1970 UTC. To represent years before 0 or after 9999, ISO 8601
permits the expansion of the year representation, but only by prior agreement between the sender and the
receiver. In the simplified ECMAScript format such an expanded year representation shall have 2 extra year
digits and is always prefixed with a + or – sign. The year 0 is considered positive and hence prefixed with a +

NOTE  Examples of extended years:

-283457-03-21T15:00:59.008Z 283458 B.C.
-000001-01T00:00:00Z 2 B.C.
+000001-01T00:00:00Z 1 B.C.
+001970-01T00:00:00Z 1970 A.D.
+002009-12-15T00:00:00Z 2009 A.D.
+287396-10-12T05:59:00.992Z 287396 A.D.

20.3.2 The Date Constructor

The Date constructor is the %Date% intrinsic object and the initial value of the Date property of the global
object. When Date is called as a function rather than as a constructor, it returns a String representing the
current time (UTC). However, if the this value passed in the call is an Object with an uninitialised
[[DateValue]] internal data property, date initialises the this object using the argument value. This permits Date
to be used both as a function for creating data strings and to perform constructor instance initialization.

NOTE  When the Date function is called the following steps are taken:

1. Let numberofArgs be the number of arguments passed to this constructor call.
3. Let O be the this value.
4. If Type(O) is Object and O has a [[DateValue]] internal data property and the value of [[DateValue]] is
   undefined, then
   a. Let y be ToNumber(year).
   b. ReturnIfAbrupt(y).
   c. Let m be ToNumber(month).
   d. ReturnIfAbrupt(m).
   e. If date is supplied then let dt be ToNumber(date); else let dt be 1.
   f. ReturnIfAbrupt(dt).
   g. If hours is supplied then let h be ToNumber(hours); else let h be 0.
   h. ReturnIfAbrupt(h).
   i. If minutes is supplied then let min be ToNumber(minutes); else let min be 0.
20.3.2.2 Date (value)

This description applies only if the Date constructor is called with exactly one argument.

When the Date function is called the following steps are taken:

1. Let numberOfArgs be the number of arguments passed to this constructor call.
3. Let O be the this value.
4. If Type(O) is Object and O has a [[DateValue]] internal data property and the value of [[DateValue]] is undefined, then
   a. If Type(value) is Object and value has a [[DateValue]] internal data property, then
      i. Let tv be thisTimeValue(value).
   b. Else, i. Let v be ToPrimitive(value).
      ii. If Type(v) is String, then
          1. Let v be the result of parsing v as a date, in exactly the same manner as for
             the parse method (20.3.3.2). If the parse resulted in an abrupt
             completion, tv is the Completion Record.
        iii. Else, i. Let tv be ToNumber(v).
   c. ReturnIfAbrupt(tv).
   d. Set the [[DateValue]] internal data property of O to TimeClip(tv).
   e. Return O.
5. Else, a. Return the result computed as if by the expression `(new Date()).toString()` where Date is
   this function and toString is the standard built-in method Date.prototype.toString.

20.3.2.3 Date ()

This description applies only if the Date constructor is called with no arguments.

When the Date function is called the following steps are taken:

1. Let numberOfArgs be the number of arguments passed to this constructor call.
2. Assert: numberOfArgs = 0.
3. Let O be the this value.
4. If Type(O) is Object and O has a [[DateValue]] internal data property and the value of [[DateValue]] is
   undefined, then
   a. Set the [[DateValue]] internal data property of O to the time value (UTC) identifying the current time.
   b. Return O.
5. Else, a. Return the result computed as if by the expression `(new Date()).toString()` where Date is
   this function and toString is the standard built-in method Date.prototype.toString.
20.3.2.4 new Date ( ... argumentsList)

Date called as part of a new expression with argument list argumentsList it performs the following steps:

1. Let \( F \) be the Date function object on which the new operator was applied.
2. Let argumentsList be the argumentsList argument of the [[Construct]] internal method that was invoked by the new operator.
3. Return the result of OrdinaryConstruct \((F, \text{argumentsList})\).

If Date is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.

20.3.3 Properties of the Date Constructor

The value of the [[Prototype]] internal data property of the Date constructor is the Function prototype object (19.2.3).

Besides the length property (whose value is 7), the Date constructor has the following properties:

20.3.3.1 Date.now()

The now function return a Number value that is the time value designating the UTC date and time of the occurrence of the call to now.

20.3.3.2 Date.parse (string)

The parse function applies the ToString operator to its argument. If ToString results in an abrupt completion the Completion Record is immediately returned. Otherwise, parse interprets the resulting String as a date and time; it returns a Number, the UTC time value corresponding to the date and time. The String may be interpreted as a local time, a UTC time, or a time in some other time zone, depending on the contents of the String. The function first attempts to parse the format of the String according to the rules called out in Date Time String Format (20.3.1.15). If the String does not conform to that format the function may fall back to any implementation-specific heuristics or implementation-specific date formats. Unrecognisable Strings or dates containing illegal element values in the format String shall cause Date.parse to return NaN.

If \( x \) is any Date object whose milliseconds amount is zero within a particular implementation of ECMAScript, then all of the following expressions should produce the same numeric value in that implementation, if all the properties referenced have their initial values:

\[
\begin{align*}
x.\text{valueOf()} \quad & \text{Date.parse}(x.\text{toString}()) \\
& \text{Date.parse}(x.\text{toUTCString}()) \\
& \text{Date.parse}(x.\text{toLocaleString}())
\end{align*}
\]

However, the expression

\[
\text{Date.parse}(x.\text{toLocaleString}())
\]

is not required to produce the same Number value as the preceding three expressions and, in general, the value produced by Date.parse is implementation-dependent when given any String value that does not conform to the Date Time String Format (20.3.1.15) and that could not be produced in that implementation by the toString or toUTCString method.

20.3.3.3 Date.prototype

The initial value of Date.prototype is the built-in Date prototype object (20.3.4).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }. 

© Ecma International 2013
20.3.3.4 Date.UTC (year, month [, date [, hours [, minutes [, seconds [, ms ] ] ] ] ])

When the \texttt{UTC} function is called with fewer than two arguments, the behaviour is implementation-dependent. When the \texttt{UTC} function is called with two to seven arguments, it computes the date from \texttt{year}, \texttt{month} and (optionally) \texttt{date}, \texttt{hours}, \texttt{minutes}, \texttt{seconds} and \texttt{ms}. The following steps are taken:

1. Let \texttt{y} be ToNumber(\texttt{year}).
2. ReturnIfAbrupt(\texttt{y}).
3. Let \texttt{m} be ToNumber(\texttt{month}).
4. ReturnIfAbrupt(\texttt{m}).
5. If \texttt{date} is supplied then let \texttt{dt} be ToNumber(\texttt{date}); else let \texttt{dt} be 1.
6. ReturnIfAbrupt(\texttt{dt}).
7. If \texttt{hours} is supplied then let \texttt{h} be ToNumber(\texttt{hours}); else let \texttt{h} be 0.
8. ReturnIfAbrupt(\texttt{h}).
9. If \texttt{minutes} is supplied then let \texttt{min} be ToNumber(\texttt{minutes}); else let \texttt{min} be 0.
10. ReturnIfAbrupt(\texttt{min}).
11. If \texttt{seconds} is supplied then let \texttt{s} be ToNumber(\texttt{seconds}); else let \texttt{s} be 0.
12. ReturnIfAbrupt(\texttt{s}).
13. If \texttt{ms} is supplied then let \texttt{milli} be ToNumber(\texttt{ms}); else let \texttt{milli} be 0.
14. ReturnIfAbrupt(\texttt{milli}).
15. If \texttt{y} is not NaN and 0 < ToInteger(\texttt{y}) < 99, then let \texttt{yr} be 1900+ToInteger(\texttt{y}); otherwise, let \texttt{yr} be \texttt{y}.
16. Return TimeClip(MakeDate(MakeDay(\texttt{yr}, \texttt{m}, \texttt{dt}), MakeTime(\texttt{h}, \texttt{min}, \texttt{s}, \texttt{milli}))).

The \texttt{length} property of the \texttt{UTC} function is 7.

NOTE The \texttt{UTC} function differs from the \texttt{Date} constructor in two ways: it returns a time value as a Number, rather than creating a Date object, and it interprets the arguments in UTC rather than as local time.

20.3.3.5 Date[ @@create ] ()

The \texttt{@@create} method of an object \texttt{F} performs the following steps:

1. Let \texttt{obj} be the result of calling OrdinaryCreateFromConstructor(\texttt{F}, "%DatePrototype%", [[DateValue]]).
2. ReturnIfAbrupt(\texttt{obj}).
3. Return \texttt{obj}.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

NOTE [[DateValue]] is initially assigned the value undefined as a flag to indicate that the instance has not yet been initialised by the \texttt{Date} constructor. This flag value is never directly exposed to ECMAScript code; hence implementation may choose to encode the flag in some other manner.

20.3.4 Properties of the Date Prototype Object

The Date prototype object is itself an ordinary object. It is not a Date instance and does not have a [[DateValue]] internal data property.

The value of the [[Prototype]] internal data property of the Date prototype object is the standard built-in Object prototype object (20.3.4).

Unless explicitly defined otherwise, the methods of the Date prototype object defined below are not generic and the \texttt{this} value passed to them must be an object that has a [[DateValue]] internal data property that has been initialised to a time value.

The abstract operation \texttt{thisTimeValue(value)} performs the following steps:

1. If Type(\texttt{value}) is Object and \texttt{value} has a [[DateValue]] internal data property, then
   a. Let \texttt{n} be the Number that is the value of \texttt{value}'s [[NumberData]] internal data property.
   b. If \texttt{n} is not undefined, then return \texttt{n}.

© Ecma International 2013
2. Throw a `TypeError` exception.

In following descriptions of functions that are properties of the Date prototype object, the phrase "this Date object" refers to the object that is the `this` value for the invocation of the function. The phrase "this time value" within the specification of a method refers to the result returned by calling the abstract operation `thisTimeValue` with the `this` value of the method invocation passed as the argument.

### 20.3.4.1 Date.prototype.constructor

The initial value of `Date.prototype.constructor` is the built-in `Date` constructor.

### 20.3.4.2 Date.prototype.getDate ( )

1. Let `t` be this time value.
2. ReturnIfAbrupt(`t`).
3. If `t` is `NaN`, return `NaN`.
4. Return `DateFromTime(LocalTime(`t`))`.

### 20.3.4.3 Date.prototype.getDay ( )

1. Let `t` be this time value.
2. ReturnIfAbrupt(`t`).
3. If `t` is `NaN`, return `NaN`.
4. Return `WeekDay(LocalTime(`t`))`.

### 20.3.4.4 Date.prototype.getFullYear ( )

1. Let `t` be this time value.
2. ReturnIfAbrupt(`t`).
3. If `t` is `NaN`, return `NaN`.
4. Return `YearFromTime(LocalTime(`t`))`.

### 20.3.4.5 Date.prototype.getHours ( )

1. Let `t` be this time value.
2. ReturnIfAbrupt(`t`).
3. If `t` is `NaN`, return `NaN`.
4. Return `HourFromTime(LocalTime(`t`))`.

### 20.3.4.6 Date.prototype.getMilliseconds ( )

1. Let `t` be this time value.
2. ReturnIfAbrupt(`t`).
3. If `t` is `NaN`, return `NaN`.
4. Return `msFromTime(LocalTime(`t`))`.

### 20.3.4.7 Date.prototype.getMinutes ( )

1. Let `t` be this time value.
2. ReturnIfAbrupt(`t`).
3. If `t` is `NaN`, return `NaN`.
4. Return `MinFromTime(LocalTime(`t`))`.

### 20.3.4.8 Date.prototype.getMonth ( )

1. Let `t` be this time value.
2. ReturnIfAbrupt(`t`).
3. If `t` is `NaN`, return `NaN`.
4. Return `MonthFromTime(LocalTime(`t`))`. 
20.3.4.9 Date.prototype.getSeconds ( )
1. Let t be this time value.
2. ReturnIfAbrupt(t).
3. If t is NaN, return NaN.
4. Return SecFromTime(LocalTime(t)).

20.3.4.10 Date.prototype.getTime ( )
1. Return this time value.

20.3.4.11 Date.prototype.getTimezoneOffset ( )
Returns the difference between local time and UTC time in minutes.
1. Let t be this time value.
2. ReturnIfAbrupt(t).
3. If t is NaN, return NaN.
4. Return (t − LocalTime(t)) / msPerMinute.

20.3.4.12 Date.prototype.getUTCDate ( )
1. Let t be this time value.
2. ReturnIfAbrupt(t).
3. If t is NaN, return NaN.
4. Return DateFromTime(t).

20.3.4.13 Date.prototype.getUTCDay ( )
1. Let t be this time value.
2. ReturnIfAbrupt(t).
3. If t is NaN, return NaN.
4. Return WeekDay(t).

20.3.4.14 Date.prototype.getUTCFullYear ( )
1. Let t be this time value.
2. ReturnIfAbrupt(t).
3. If t is NaN, return NaN.
4. Return YearFromTime(t).

20.3.4.15 Date.prototype.getUTCHours ( )
1. Let t be this time value.
2. ReturnIfAbrupt(t).
3. If t is NaN, return NaN.
4. Return HourFromTime(t).

20.3.4.16 Date.prototype.getUTCMilliseconds ( )
1. Let t be this time value.
2. ReturnIfAbrupt(t).
3. If t is NaN, return NaN.
4. Return msFromTime(t).

20.3.4.17 Date.prototype.getUTCMinutes ( )
1. Let t be this time value.
2. ReturnIfAbrupt(t).
3. If t is NaN, return NaN.
4. Return MinFromTime(t).

20.3.4.18 Date.prototype.getUTCMonth ()
1. Let \( t \) be this time value.
2. ReturnIfAbrupt(t).
3. If \( t \) is NaN, return NaN.
4. Return MonthFromTime(t).

20.3.4.19 Date.prototype.getUTCSeconds ()
1. Let \( t \) be this time value.
2. ReturnIfAbrupt(t).
3. If \( t \) is NaN, return NaN.
4. Return SecFromTime(t).

20.3.4.20 Date.prototype.setDate (date)
1. Let \( t \) be the result of LocalTime(this time value); but if this time value is NaN, let \( t \) be +0.
2. Let \( y \) be ToNumber(year).
3. If month is not specified, then let \( m \) be MonthFromTime(t); otherwise, let \( m \) be ToNumber(month).
4. If date is not specified, then let \( dt \) be DateFromTime(t); otherwise, let \( dt \) be ToNumber(date).
5. Let \( newDate \) be MakeDate(MakeDay(y, m, dt), TimeWithinDay(t)).
6. Let \( u \) be TimeClip(UTC(newDate)).
7. Set the [[DateValue]] internal data property of this Date object to \( u \).
8. Return \( u \).

20.3.4.21 Date.prototype.setFullYear (year [, month [, date [,]]])
If month is not specified, this behaves as if month were specified with the value getMonth().
If date is not specified, this behaves as if date were specified with the value getDate().
1. Let \( t \) be the result of LocalTime(this time value), but if this time value is NaN, let \( t \) be +0.
2. Let \( y \) be ToNumber(year).
3. If month is not specified, then let \( m \) be MonthFromTime(t); otherwise, let \( m \) be ToNumber(month).
4. If date is not specified, then let \( dt \) be DateFromTime(t); otherwise, let \( dt \) be ToNumber(date).
5. Let \( newDate \) be MakeDate(MakeDay(y, m, dt), TimeWithinDay(t)).
6. Let \( u \) be TimeClip(UTC(newDate)).
7. Set the [[DateValue]] internal data property of this Date object to \( u \).
8. Return \( u \).

The length property of the setFullYear method is 3.

20.3.4.22 Date.prototype.setHours (hour [, min [, sec [, ms [,]]]])
If min is not specified, this behaves as if min were specified with the value getMinutes().
If sec is not specified, this behaves as if sec were specified with the value getSeconds().
If ms is not specified, this behaves as if ms were specified with the value getMilliseconds().
1. Let \( t \) be the result of LocalTime(this time value).
2. Let \( h \) be ToNumber(hour).
3. If \( t \) is not specified, then let \( m \) be MinFromTime(t); otherwise, let \( m \) be ToNumber(min).
4. If sec is not specified, then let \( x \) be SecFromTime(t); otherwise, let \( x \) be ToNumber(sec).
5. If ms is not specified, then let \( milli \) be msFromTime(t); otherwise, let \( milli \) be ToNumber(ms).
6. Let \( date \) be MakeDate(Day(t), MakeTime(h, m, x, milli)).
7. Let \( u \) be TimeClip(UTC(date)).
8. Set the [[DateValue]] internal data property of this Date object to \( u \).
9. Return \( u \).
The `length` property of the `setHours` method is 4.

### 20.3.4.23 Date.prototype.setMilliseconds (ms)

1. Let `t` be the result of `LocalTime(this time value)`.
2. Let `time` be `MakeTime(HourFromTime(t), MinFromTime(t), SecFromTime(t), ToNumber(ms))`.
3. Let `u` be `TimeClip(UTC(MakeDate(Day(t), time)))`.
4. Set the `[[DateValue]]` internal data property of this Date object to `u`.
5. Return `u`.

### 20.3.4.24 Date.prototype.setMinutes (min [, sec [, ms] ] )

*If `sec` is not specified, this behaves as if `sec` were specified with the value `getSeconds()`.*

*If `ms` is not specified, this behaves as if `ms` were specified with the value `getMilliseconds()`.*

1. Let `t` be the result of `LocalTime(this time value)`.
2. Let `m` be `ToNumber(min)`.
3. If `sec` is not specified, then let `s` be `SecFromTime(t);` otherwise, let `s` be `ToNumber(sec)`.
4. If `ms` is not specified, then let `milli` be `msFromTime(t)`; otherwise, let `milli` be `ToNumber(ms)`.
5. Let `date` be `MakeDate(MakeDay(YearFromTime(t)), MakeTime(HourFromTime(t), m, s, milli))`.
6. Let `u` be `TimeClip(UTC(date))`.
7. Set the `[[DateValue]]` internal data property of this Date object to `u`.
8. Return `u`.

The `length` property of the `setMinutes` method is 3.

### 20.3.4.25 Date.prototype.setMonth (month [, date ] )

*If `date` is not specified, this behaves as if `date` were specified with the value `getDate()`.*

1. Let `t` be the result of `LocalTime(this time value)`.
2. Let `m` be `ToNumber(month)`.
3. If `date` is not specified, then let `dt` be `DateFromTime(t);` otherwise, let `dt` be `ToNumber(date)`.
4. Let `newDate` be `MakeDate(MakeDay(YearFromTime(t), m, dt), TimeWithinDay(t))`.
5. Let `u` be `TimeClip(UTC(newDate))`.
6. Set the `[[DateValue]]` internal data property of this Date object to `u`.
7. Return `u`.

The `length` property of the `setMonth` method is 2.

### 20.3.4.26 Date.prototype.setSeconds (sec [, ms] )

*If `ms` is not specified, this behaves as if `ms` were specified with the value `getMilliseconds()`.*

1. Let `t` be the result of `LocalTime(this time value)`.
2. Let `s` be `ToNumber(sec)`.
3. If `ms` is not specified, then let `milli` be `msFromTime(t);` otherwise, let `milli` be `ToNumber(ms)`.
4. Let `date` be `MakeDate(Day(t), MakeTime(HourFromTime(t), MinFromTime(t), s, milli))`.
5. Let `u` be `TimeClip(UTC(date))`.
6. Set the `[[DateValue]]` internal data property of this Date object to `u`.
7. Return `u`.

The `length` property of the `setSeconds` method is 2.

### 20.3.4.27 Date.prototype.setTime (time)

1. Let `v` be `TimeClip(ToNumber(time))`.
2. ReturnIfAbrupt(`v`).
3. Set the [[DateValue]] internal data property of this Date object to v.
4. Return v.

20.3.4.28 `Date.prototype.setUTCDate(date)`

1. Let t be this time value.
2. ReturnIfAbrupt(t).
3. Let dt be ToNumber(date).
4. Let newDate be MakeDate(MakeDay(YearFromTime(t), MonthFromTime(t), dt), TimeWithinDay(t)).
5. Let v be TimeClip(newDate).
6. Set the [[DateValue]] internal data property of this Date object to v.
7. Return v.

20.3.4.29 `Date.prototype.setUTCFullYear(year [, month [, date [,] ]])`

If `month` is not specified, this behaves as if `month` were specified with the value `getUTCMonth()`.

If `date` is not specified, this behaves as if `date` were specified with the value `getUTCDate()`.

1. Let t be this time value; but if this time value is NaN, let t be +0.
2. ReturnIfAbrupt(t).
3. Let y be ToNumber(year).
4. If `month` is not specified, then let m be MonthFromTime(t); otherwise, let m be ToNumber(month).
5. If `date` is not specified, then let dt be DateFromTime(t); otherwise, let dt be ToNumber(date).
6. Let newDate be MakeDate(MakeDay(y, m, dt), TimeWithinDay(t)).
7. Let v be TimeClip(newDate).
8. Set the [[DateValue]] internal data property of this Date object to v.

The length property of the `setUTCFullYear` method is 3.

20.3.4.30 `Date.prototype.setUTCHours (hour [, min [, sec [, ms [,] ]])`)

If `min` is not specified, this behaves as if `min` were specified with the value `getUTCMilliseconds()`.

If `sec` is not specified, this behaves as if `sec` were specified with the value `getUTCSeconds()`.

If `ms` is not specified, this behaves as if `ms` were specified with the value `getUTCMilliseconds()`.

1. Let t be this time value.
2. ReturnIfAbrupt(t).
3. Let h be ToNumber(hour).
4. If `min` is not specified, then let m be MinFromTime(t); otherwise, let m be ToNumber(min).
5. If `sec` is not specified, then let s be SecFromTime(t); otherwise, let s be ToNumber(sec).
6. If `ms` is not specified, then let milli be msFromTime(t); otherwise, let milli be ToNumber(ms).
7. Let newDate be MakeDate(Day(t), MakeTime(h, m, s, milli))
8. Let v be TimeClip(newDate).
9. Set the [[DateValue]] internal data property of this Date object to v.
10. Return v.

The length property of the `setUTCHours` method is 4.

20.3.4.31 `Date.prototype.setUTCMilliseconds (ms)`

1. Let t be this time value.
2. ReturnIfAbrupt(t).
3. Let time be MakeTime(HourFromTime(t), MinFromTime(t), SecFromTime(t), ToNumber(ms)).
4. Let v be TimeClip(MakeDate(Day(t), time)).
5. Set the [[DateValue]] internal data property of this Date object to v.
6. Return \( v \).

**20.3.4.32 Date.prototype.setUTCMinutes (min [, sec [, ms ]])**

If \( ms \) is not specified, this behaves as if \( sec \) were specified with the value \( \text{getUTCSeconds}() \).

If \( ms \) is not specified, this function behaves as if \( ms \) were specified with the value return by \( \text{getUTCMilliseconds}() \).

1. Let \( t \) be this time value.
2. ReturnIfAbrupt(\( t \)).
3. Let \( m \) be ToNumber(\( \text{min} \)).
4. If \( \text{sec} \) is not specified, then let \( s \) be SecFromTime(\( t \)); otherwise, let \( s \) be ToNumber(\( \text{sec} \)).
5. If \( \text{ms} \) is not specified, then let \( \text{milli} \) be msFromTime(\( t \)); otherwise, let \( \text{milli} \) be ToNumber(\( \text{ms} \)).
6. Let \( \text{date} \) be \( \text{MakeDate}([\text{Day}()], \text{MakeTime}([\text{Hour}()], \text{MinFromTime}([\text{t}], s, \text{milli}])) \).
7. Let \( v \) be TimeClip(\( \text{date} \)).
8. Set the [[DateValue]] internal data property of this Date object to \( v \).
9. Return \( v \).

The length property of the \( \text{setUTCMinutes} \) method is 3.

**20.3.4.33 Date.prototype.setUTCMonth (month [, date])**

If \( \text{date} \) is not specified, this behaves as if \( \text{date} \) were specified with the value \( \text{getUTCDate}() \).

1. Let \( t \) be this time value.
2. ReturnIfAbrupt(\( t \)).
3. Let \( m \) be ToNumber(\( \text{month} \)).
4. If \( \text{date} \) is not specified, then let \( \text{dt} \) be DateFromTime(\( t \)); otherwise, let \( \text{dt} \) be ToNumber(\( \text{date} \)).
5. Let \( \text{newDate} \) be \( \text{MakeDate}([\text{YearFromTime}(), m, \text{dt}], \text{TimeWithinDay}()) \).
6. Let \( v \) be TimeClip(\( \text{newDate} \)).
7. Set the [[DateValue]] internal data property of this Date object to \( v \).
8. Return \( v \).

The length property of the \( \text{setUTCMonth} \) method is 2.

**20.3.4.34 Date.prototype.setUTCMilliseconds (sec [, ms])**

If \( \text{ms} \) is not specified, this behaves as if \( \text{ms} \) were specified with the value \( \text{getUTCMilliseconds}() \).

1. Let \( t \) be this time value.
2. ReturnIfAbrupt(\( t \)).
3. Let \( k \) be ToNumber(\( \text{sec} \)).
4. If \( \text{ms} \) is not specified, then let \( \text{milli} \) be msFromTime(\( t \)); otherwise, let \( \text{milli} \) be ToNumber(\( \text{ms} \)).
5. Let \( \text{date} \) be \( \text{MakeDate}([\text{Day}()], \text{MakeTime}([\text{HourFromTime}(), \text{MinFromTime}(), s, \text{milli}])) \).
6. Let \( v \) be TimeClip(\( \text{date} \)).
7. Set the [[DateValue]] internal data property of this Date object to \( v \).
8. Return \( v \).

The length property of the \( \text{setUTCMilliseconds} \) method is 2.

**20.3.4.35 Date.prototype.toDateString ()**

This function returns a String value. The contents of the String are implementation-dependent, but are intended to represent the “date” portion of the Date in the current time zone in a convenient, human-readable form.
20.3.4.36 Date.prototype.toISOString ()

This function returns a String value representing the instance in time corresponding to this time value. The format of the String is the Date Time string format defined in 20.3.1.15. All fields are present in the String. The time zone is always UTC, denoted by the suffix Z. If this time value is not a finite Number a RangeError exception is thrown.

20.3.4.37 Date.prototype.toJSON ( key )

This function provides a String representation of a Date object for use by JSON.stringify (24.3.3).

When the toJSON method is called with argument key, the following steps are taken:

1. Let O be the result of calling ToObject, giving it the this value as its argument.
2. Let tv be ToPrimitive(O, hint Number).
3. If tv is a Number and is not finite, return null.
4. Let toISO be the result of Get(O, "toISOString").
5. ReturnIfAbrupt(toISO).
6. If IsCallable(toISO) is false, throw a TypeError exception.
7. Return the result of calling the [[Call]] internal method of toISO with O as this Argument and an empty List as argumentsList.

NOTE 1 The argument is ignored.

NOTE 2 The toJSON function is intentionally generic; it does not require that its this value be a Date object. Therefore, it can be transferred to other kinds of objects for use as a method. However, it does require that any such object have a toISOString method. An object is free to use the argument key to filter its stringification.

20.3.4.38 Date.prototype.toLocaleDateString ()

This function returns a String value. The contents of the String are implementation-dependent, but are intended to represent the “date” portion of the Date in the current time zone in a convenient, human-readable form that corresponds to the conventions of the host environment’s current locale.

NOTE The first parameter to this function is likely to be used in a future version of this standard; it is recommended that implementations do not use this parameter position for anything else.

20.3.4.39 Date.prototype.toLocaleString ()

This function returns a String value. The contents of the String are implementation-dependent, but are intended to represent the Date in the current time zone in a convenient, human-readable form that corresponds to the conventions of the host environment’s current locale.

NOTE The first parameter to this function is likely to be used in a future version of this standard; it is recommended that implementations do not use this parameter position for anything else.

20.3.4.40 Date.prototype.toLocaleTimeString ()

This function returns a String value. The contents of the String are implementation-dependent, but are intended to represent the “time” portion of the Date in the current time zone in a convenient, human-readable form that corresponds to the conventions of the host environment’s current locale.

NOTE The first parameter to this function is likely to be used in a future version of this standard; it is recommended that implementations do not use this parameter position for anything else.
20.3.4.41 Date.prototype.toString ( )

This function returns a String value. If this time value is NaN, the String value is "Invalid Date", otherwise the contents of the String are implementation-dependent, but are intended to represent the Date in the current time zone in a convenient, human-readable form.

NOTE For any Date value d whose milliseconds amount is zero, the result of Date.parse(d.toString()) is equal to d.valueOf(). See 20.3.3.2.

20.3.4.42 Date.prototype.toTimeString ( )

This function returns a String value. The contents of the String are implementation-dependent, but are intended to represent the "time" portion of the Date in the current time zone in a convenient, human-readable form.

20.3.4.43 Date.prototype.toUTCString ( )

This function returns a String value. The contents of the String are implementation-dependent, but are intended to represent this time value in a convenient, human-readable form in UTC.

NOTE The intent is to produce a String representation of a date that is more-readable than the format specified in 20.3.1.15. It is not essential that the chosen format be unambiguous or easily machine parsable. If an implementation does not have a preferred human-readable format it is recommended to use the format defined in 20.3.1.15 but with a space rather than a "T" used to separate the date and time elements.

20.3.4.44 Date.prototype.valueOf ( )

The valueOf function returns a Number, which is this time value.

20.3.4.45 Date.prototype @@ToPrimitive ( hint )

This function is called by ECMAScript language operators to convert an object to a primitive value. The allowed values for hint are "default", "number", and "string". Date objects, are unique among built-in ECMAScript object in that they treat "default" as being equivalent to "string". All other built-in ECMAScript objects treat "default" as being equivalent to "number".

When the @@ToPrimitive method is called with argument hint, the following steps are taken:

1. Let O be the this value.
2. If Type(O) is not Object, then throw a TypeError exception.
3. If hint is the string value "string" or the string value "default", then
   a. Let tryFirst be "string".
4. Else if hint is the string value "number", then
   a. Let tryFirst be "number".
5. Else, throw a TypeError exception.
6. Return the result of OrdinaryToPrimitive(O,tryFirst).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

20.3.5 Properties of Date Instances

Date instances are ordinary objects that inherit properties from the Date prototype object. Date instances also have a [[DateValue]] internal data property. The [[DateValue]] internal data property is the time value represented by this Date object.
21 Text Processing

21.1 String Objects

21.1.1 The String Constructor

The String constructor is the %String% intrinsic object and the initial value of the String property of the global object. When String is called as a function rather than as a constructor, it performs a type conversion. However, if the this value value passed in the call is an Object with an uninitialised [[StringData]] internal data property, it initialises the this value using the argument value. This permits String to be used both to perform type conversion and to perform constructor instance initialization.

The String constructor is designed to be subclassable. It may be used as the value of an extends clause of a class declaration. Subclass constructors that intended to inherit the specified String behaviour must include a super call to the String constructor to initialise the [[StringData]] state of subclass instances.

21.1.1.1 String ([value])

Returns a String value (not a String object) computed by ToString(value). If value is not supplied, the empty String "" is returned.

When String is called with argument value, the following steps are taken:

1. Let O be the this value.
2. If no arguments were passed to this function invocation, then let s be "".
3. Else, let s be ToString(value).
4. ReturnIfAbrupt(s).
5. If Type(O) is Object and O has a [[StringData]] internal data property and the value of [[StringData]] is undefined, then
   a. Let length be the number of code unit elements in s.
   b. Let status be the result of DefinePropertyOrThrow(O, "length", Property Descriptor{[[Value]]: length, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false}).
   c. ReturnIfAbrupt(status).
   d. Set the value of O’s [[StringData]] internal data property to s.
   e. Return O.
6. Return s.

21.1.1.2 new String (...argumentsList)

String called as part of a new expression, it initialises a newly created exotic String object:

1. Let F be the String function object on which the new operator was applied.
2. Let argumentsList be the argumentsList argument of the [[Construct]] internal method that was invoked by the new operator.
3. Return the result of OrdinaryConstruct(F, argumentsList).

If String is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.

21.1.2 Properties of the String Constructor

The value of the [[Prototype]] internal data property of the String constructor is the standard built-in Function prototype object (19.2.3).

Besides the length property (whose value is 1), the String constructor has the following properties:
21.1.2.1 String.fromCharCode(...codeUnits)

The `String.fromCharCode` function may be called with a variable number of arguments which form the rest parameter `codeUnits`. The following steps are taken:

1. Assert: `codeUnits` is a well-formed rest parameter object.
2. Let `length` be the result of `Get(codeUnits, "length")`.
3. Let `elements` be a new List.
4. Let `nextIndex` be 0.
5. Repeat while `nextIndex < length`
   a. Let `next` be the result of `Get(codeUnits, String(nextIndex))`.
   b. Let `nextCU` be `ToUint16(next)`.
   c. ReturnIfAbrupt(nextCU).
   d. Append `nextCU` to the end of `elements`.
   e. Let `nextIndex` be `nextIndex + 1`.
6. Return the String value whose elements are, in order, the elements in the List `elements`. If `length` is 0, the empty string is returned.

The `length` property of the `fromCharCode` function is 1.

21.1.2.2 String.fromCodePoint(...codePoints)

The `String.fromCodePoint` function may be called with a variable number of arguments which form the rest parameter `codePoints`. The following steps are taken:

1. Assert: `codePoints` is a well-formed rest parameter object.
2. Let `length` be the result of `Get(codePoints, "length")`.
3. Let `elements` be a new List.
4. Let `nextIndex` be 0.
5. Repeat while `nextIndex < length`
   a. Let `next` be the result of `Get(codePoints, String(nextIndex))`.
   b. Let `nextCP` be `ToNumber(next)`.
   c. ReturnIfAbrupt(nextCP).
   d. If `SameValue(nextCP, ToInteger(nextCP))` is false, then throw a `RangeError` exception.
   e. If `nextCP < 0` or `nextCP > 0x10FFFF`, then throw a `RangeError` exception.
   f. Append the elements of the UTF-16 Encoding (clause 6) of `nextCP` to the end of `elements`.
   g. Let `nextIndex` be `nextIndex + 1`.
6. Return the String value whose elements are, in order, the elements in the List `elements`. If `length` is 0, the empty string is returned.

The `length` property of the `fromCodePoint` function is 0.

21.1.2.3 String.prototype

The initial value of `String.prototype` is the standard built-in String prototype object (21.1.3).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

21.1.2.4 String.raw (callSite, ...substitutions)

The `String.raw` function may be called with a variable number of arguments. The first argument is `callSite` and the remainder of the arguments form the rest parameter `substitutions`. The following steps are taken:

1. Assert: `substitutions` is a well-formed rest parameter object.
2. Let `cooked` be `ToObject(callSite)`.
3. ReturnIfAbrupt(cooked).
4. Let `rawValue` be the result of `Get(cooked, "raw")`.
5. Let `raw` be `ToObject(rawValue)`.
6. ReturnIfAbrupt(raw).
7. Let len be the result of Get(raw, \"length\")
8. Let literalSegments be ToLength(len).
9. ReturnIfAbrupt(literalSegments).
10. If literalSegments ≤ 0, then return the empty string.
11. Let stringElements be a new List.
12. Let nextIndex be 0.
13. Repeat
   a. Let nextKey be ToString(nextIndex).
   b. Let next be the result of Get(raw, nextKey).
   c. Let nextSeg be ToString(next).
   d. ReturnIfAbrupt(nextSeg).
   e. Append in order the code unit elements of nextSeg to the end of stringElements.
      i. Return the string whose elements are, in order, the elements in the List stringElements. If length is 0, the empty string is returned.
   g. Let next be the result of Get(substitutions, nextKey).
   h. Let nextSub be ToString(next).
   i. ReturnIfAbrupt(nextSub).
   j. Append in order the code unit elements of nextSub to the end of stringElements.
   k. Let nextIndex be nextIndex + 1.

The length property of the raw function is 1.

NOTE String.raw is intended for use as a tag function of a Tagged Template String (12.2.6). When called as such the first argument will be a well formed template call site object and the rest parameter will contain the substitution values.

21.1.2.5 String[@@create]()

The @@create method of an object F performs the following steps:
1. Let F be the this value.
2. Let proto be the result of GetPrototypeFromConstructor(F, \"StringPrototype\")
3. ReturnIfAbrupt(proto).
4. Let obj be the result of calling StringCreate(proto).
5. Return obj.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

NOTE [[StringData]] is initially assigned the value undefined as a flag to indicate that the instance has not yet been initialised by the String constructor. This flag value is never directly exposed to ECMAScript code; hence implementation may choose to encode the flag in some other manner.

21.1.3 Properties of the String Prototype Object

The String prototype object is itself an ordinary object. It is not a String instance and does not have a [[StringData]] internal data property.

The value of the [[Prototype]] internal data property of the String prototype object is the standard built-in Object prototype object (19.1.4).

Unless explicitly stated otherwise, the methods of the String prototype object defined below are not generic and the this value passed to them must be either a String value or an object that has a [[StringData]] internal data property that has been initialised to a String value.

The abstract operation thisStringValue(value) performs the following steps:
1. If Type(value) is String, return value.
2. If Type(value) is Object and value has a [[StringData]] internal data property, then
   a. Let s be the value of value’s [[StringData]] internal data property.
b. If \( s \) is not \texttt{undefined}, then return \( s \).

3. Throw a \texttt{TypeError} exception.

The phrase “this String value” within the specification of a method refers to the result returned by calling the abstract operation \texttt{thisStringValue} with the this value of the method invocation passed as the argument.

### 21.1.3.1 \texttt{String.prototype.charAt(pos)}

**NOTE** Returns a single element String containing the code unit at element position \( pos \) in the String value resulting from converting this object to a String. If there is no element at that position, the result is the empty String. The result is a String value, not a String object.

If \( pos \) is a value of Number type that is an integer, then the result of \( \texttt{x.charAt(pos)} \) is equal to the result of \( \texttt{x.substring(pos, pos+1)} \).

When the \texttt{charAt} method is called with one argument \( pos \), the following steps are taken:

1. Let \( O \) be CheckObjectCoercible(this value).
2. Let \( S \) be \texttt{ToString}(\( O \)).
3. ReturnIfAbrupt(\( S \)).
4. Let position be \texttt{ToInteger(pos)}.
5. ReturnIfAbrupt(position).
6. Let size be the number of elements in \( S \).
7. If \( position < 0 \) or \( position \geq size \), return the empty String.
8. Return a String of length 1, containing one code unit from \( S \), namely the code unit at position \( position \), where the first (leftmost) code unit in \( S \) is considered to be at position 0, the next one at position 1, and so on.

**NOTE** The \texttt{charAt} function is intentionally generic; it does not require that its this value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

### 21.1.3.2 \texttt{String.prototype.charCodeAt(pos)}

**NOTE** Returns a Number (a nonnegative integer less than \( 2^{16} \)) that is the code unit value of the string element at position \( pos \) in the String resulting from converting this object to a String. If there is no element at that position, the result is \texttt{NaN}.

When the \texttt{charCodeAt} method is called with one argument \( pos \), the following steps are taken:

1. Let \( O \) be CheckObjectCoercible(this value).
2. Let \( S \) be \texttt{ToString}(\( O \)).
3. ReturnIfAbrupt(\( S \)).
4. Let position be \texttt{ToInteger(pos)}.
5. ReturnIfAbrupt(position).
6. Let size be the number of elements in \( S \).
7. If \( position < 0 \) or \( position \geq size \), return \texttt{NaN}.
8. Return a value of Number type, whose value is the code unit value of the element at position \( position \) in the String \( S \), where the first (leftmost) element in \( S \) is considered to be at position 0, the next one at position 1, and so on.

**NOTE** The \texttt{charCodeAt} function is intentionally generic; it does not require that its this value be a String object. Therefore it can be transferred to other kinds of objects for use as a method.

### 21.1.3.3 \texttt{String.prototype.codePointAt(pos)}

**NOTE** Returns a Number (a nonnegative integer less than \( 1114112 \)) that is the UTF-16 encoded code point value starting at the string element at position \( pos \) in the String resulting from converting this object to a String. If there is no element at that position, the result is \texttt{NaN}. If a valid UTF-16 surrogate pair does not begin at \( pos \), the result is the code unit at \( pos \).

Commented [AWB9133]: Perhaps BMPCharAt should be provided as an alias for this method and charAt should be marked as obsolete.

Commented [AWB9134]: Do we also need UnicodeCharAt that returns a string of length 1 or 2?
When the `codePointAt` method is called with one argument `pos`, the following steps are taken:

1. Let `O` be `CheckObjectCoercible(this value)`.  
2. Let `S` be `ToString(O)`.  
3. ReturnIfAbrupt(S).  
4. Let `position` be `ToInteger(pos)`.  
5. ReturnIfAbrupt(position).  
6. Let `size` be the number of elements in `S`.  
7. If `position < 0` or `position ≥ size`, return `undefined`.  
8. Let `first` be the code unit value of the element at index `position` in the String `S`.  
9. If `first < 0xD800` or `first > 0xDBFF` or `position + 1 = size`, then return `first`.  
10. Let `second` be the code unit value of the element at index `position + 1` in the String `S`.  
11. If `second < 0xDC00` or `second > 0xDFFF`, then return `first`.  
12. Return `((first − 0xD800) × 1024) + (second − 0xDC00) + 0x10000`.  

**NOTE** The `codePointAt` function is intentionally generic; it does not require that its `this` value be a String object. Therefore it can be transferred to other kinds of objects for use as a method.

### 21.1.3.4 `String.prototype.concat ( ...args )`

**NOTE** When the `concat` method is called with zero or more arguments, it returns a String consisting of the string elements of this object (converted to a String) followed by the string elements of each of the arguments converted to a String. The result is a String value, not a String object.

The following steps are taken:

1. Assert: `args` is a well-formed rest parameter object.  
2. Let `O` be `CheckObjectCoercible(this value)`.  
3. Let `S` be `ToString(O)`.  
4. ReturnIfAbrupt(S).  
5. Let `args` be an internal list that is a copy of the argument list passed to this function.  
7. Repeat, while `args` is not empty  
   a. Remove the first element from `args` and let `next` be the value of that element.  
   b. Let `nextString` be `ToString(next)`.  
   c. ReturnIfAbrupt(nextString).  
   d. Let `R` be the String value consisting of the string elements in the previous value of `R` followed by the string elements of `nextString`.  
8. Return `R`.  

The `length` property of the `concat` method is `1`.  

**NOTE** The `concat` function is intentionally generic; it does not require that its `this` value be a String object. Therefore it can be transferred to other kinds of objects for use as a method.

### 21.1.3.5 `String.prototype.constructor`

The initial value of `String.prototype.constructor` is the built-in `String` constructor.

### 21.1.3.6 `String.prototype.contains ( searchString, position = 0 )`

The `contains` method takes two arguments, `searchString` and `position`, and performs the following steps:

1. Let `O` be `CheckObjectCoercible(this value)`.  
2. Let `S` be `ToString(O)`.  
3. ReturnIfAbrupt(S).  
4. Let `searchStr` be `ToString(searchString)`.  
5. ReturnIfAbrupt(searchStr).  
6. Let `pos` be `ToInteger(position)`. (If `position` is `undefined`, this step produces the value `0`).  
7. ReturnIfAbrupt(pos).
8. Let \( \text{len} \) be the number of elements in \( S \).
9. Let \( \text{start} \) be \( \min(\text{max}(\text{pos}, 0), \text{len}) \).
10. Let \( \text{searchLen} \) be the number of elements in \( \text{searchStr} \).
11. If there exists any integer \( k \) not smaller than \( \text{start} \) such that \( k + \text{searchLen} \) is not greater than \( \text{len} \), and for all nonnegative integers \( j \) less than \( \text{searchLen} \), the character at position \( k+j \) of \( S \) is the same as the character at position \( j \) of \( \text{searchStr} \), return \( \text{true} \); but if there is no such integer \( k \), return \( \text{false} \).

The \text{length} property of the \text{contains} method is 1.

\text{NOTE 1} If \( \text{searchString} \) appears as a substring of the result of converting this object to a String, at one or more positions that are greater than or equal to \( \text{position} \), then return \( \text{true} \); otherwise, returns \( \text{false} \). If \( \text{position} \) is \( \text{undefined} \), 0 is assumed, so as to search all of the String.

\text{NOTE 2} The \text{contains} function is intentionally generic; it does not require that its \text{this} value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.7 \text{String.prototype.endsWith}(\text{searchString}, \text{endPosition})

The following steps are taken:
1. Let \( O \) be \text{CheckObjectCoercible}(\text{this} value).
2. Let \( S \) be \text{ToString}(O).
3. ReturnIfAbrupt(S).
4. Let \( \text{searchStr} \) be \text{ToString}(\text{searchString}).
5. ReturnIfAbrupt(\text{searchStr}).
6. Let \( \text{len} \) be the number of elements in \( S \).
7. If \( \text{endPosition} \) is \( \text{undefined} \), let \( \text{pos} \) be \( \text{len} \); else let \( \text{pos} \) be \( \text{ToInteger}(<\text{endPosition}>\)).
8. ReturnIfAbrupt(\text{pos}).
9. Let \( \text{end} \) be \( \min(\max(\text{pos}, 0), \text{len}) \).
10. Let \( \text{searchLength} \) be the number of elements in \( \text{searchStr} \).
11. Let \( \text{start} = \text{end} - \text{searchLength} \).
12. If \( \text{start} \) is less than 0, return \( \text{false} \).
13. If the \( \text{searchLength} \) sequence of elements of \( S \) starting at \( \text{start} \) is the same as the full element sequence of \( \text{searchStr} \), return \( \text{true} \).
14. Otherwise, return \( \text{false} \).

The \text{length} property of the \text{endsWith} method is 1.

\text{NOTE 1} Returns \( \text{true} \) if the sequence of elements of \( \text{searchString} \) converted to a String is the same as the corresponding elements of this object (converted to a String) starting at \( \text{endPosition} - \text{length}(\text{this}) \). Otherwise returns \( \text{false} \).

\text{NOTE 2} The \text{endsWith} function is intentionally generic; it does not require that its \text{this} value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.8 \text{String.prototype.indexOf}(\text{searchString}, \text{position})

If \( \text{searchString} \) appears as a substring of the result of converting this object to a String, at one or more positions that are greater than or equal to \( \text{position} \), then the index of the smallest such position is returned; otherwise, -1 is returned. If \( \text{position} \) is \( \text{undefined} \), 0 is assumed, so as to search all of the String.

The \text{indexOf} method takes two arguments, \text{searchString} and \text{position}, and performs the following steps:
1. Let \( O \) be \text{CheckObjectCoercible}(\text{this} value).
2. Let \( S \) be \text{ToString}(O).
3. ReturnIfAbrupt(S).
4. Let \( \text{searchStr} \) be \text{ToString}(\text{searchString}).
5. ReturnIfAbrupt(\text{searchStr}).
6. Let \( \text{pos} \) be \( \text{ToInteger}(<\text{position}>\) (If \( \text{position} \) is \( \text{undefined} \), this step produces the value 0).
7. ReturnIfAbrupt(\text{pos}).
8. Let \( \text{len} \) be the number of elements in \( S \).
9. Let \( \text{start} \) be \( \min(\max(pos, 0), \text{len}) \).
10. Let \( \text{searchLen} \) be the number of elements in \( \text{searchStr} \).
11. Return the smallest possible integer \( k \) not smaller than \( \text{start} \) such that \( k + \text{searchLen} \) is not greater than \( \text{len} \), and for all nonnegative integers \( j \) less than \( \text{searchLen} \), the code unit at position \( k+j \) of \( S \) is the same as the code unit at position \( j \) of \( \text{searchStr} \); but if there is no such integer \( k \), then return the value \(-1\).

The length property of the \( \text{indexOf} \) method is 1.

NOTE The \( \text{indexOf} \) function is intentionally generic; it does not require that its this value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.9 \( \text{String.prototype.lastIndexOf} \) (\( \text{searchString} \), \( \text{position} \))

If \( \text{searchString} \) appears as a substring of the result of converting this object to a String at one or more positions that are smaller than or equal to \( \text{position} \), then the index of the greatest such position is returned; otherwise, \(-1\) is returned. If \( \text{position} \) is \( \text{undefined} \), the length of the String value is assumed, so as to search all of the String.

The \( \text{lastIndexOf} \) method takes two arguments, \( \text{searchString} \) and \( \text{position} \), and performs the following steps:

1. Let \( O \) be \( \text{CheckObjectCoercible}(\text{this value}) \).
2. Let \( S \) be \( \text{ToString}(O) \).
3. ReturnIfAbrupt(S).
4. Let \( \text{searchStr} \) be \( \text{ToString}(\text{searchString}) \).
5. ReturnIfAbrupt(searchStr).
6. Let \( \text{numPos} \) be \( \text{ToNumber}(\text{position}) \). (If \( \text{position} \) is \( \text{undefined} \), this step produces the value \( \text{NaN} \).)
7. ReturnIfAbrupt(numPos).
8. Let \( \text{len} \) be the number of elements in \( S \).
9. Let \( \text{start} \) be \( \min(\max(pos, 0), \text{len}) \).
10. Let \( \text{searchLen} \) be the number of elements in \( \text{searchStr} \).
11. Return the largest possible nonnegative integer \( k \) not larger than \( \text{start} \) such that \( k + \text{searchLen} \) is not greater than \( \text{len} \), and for all nonnegative integers \( j \) less than \( \text{searchLen} \), the code unit at position \( k+j \) of \( S \) is the same as the code unit at position \( j \) of \( \text{searchStr} \); but if there is no such integer \( k \), then return the value \(-1\).

The length property of the \( \text{lastIndexOf} \) method is 1.

NOTE The \( \text{lastIndexOf} \) function is intentionally generic; it does not require that its this value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.10 \( \text{String.prototype.localeCompare} \) (that)

When the \( \text{localeCompare} \) method is called with one argument that, it returns a Number other than \( \text{NaN} \) that represents the result of a locale-sensitive String comparison of the this value (converted to a String) with that (converted to a String). The two Strings are \( S \) and \( \text{That} \). The two Strings are compared in an implementation-defined fashion. The result is intended to order String values in the sort order specified by the system default locale, and will be negative, zero, or positive, depending on whether \( S \) comes before \( \text{That} \) in the sort order, the Strings are equal, or \( S \) comes after \( \text{That} \) in the sort order, respectively.

Before perform the comparisons the following steps are performed to prepare the Strings:

1. Let \( O \) be \( \text{CheckObjectCoercible}(\text{this value}) \).
2. Let \( S \) be \( \text{ToString}(O) \).
3. ReturnIfAbrupt(S).
4. Let \( \text{That} \) be \( \text{ToString}(\text{that}) \).
5. ReturnIfAbrupt(That).
The `localeCompare` method, if considered as a function of two arguments `this` and `that`, is a consistent comparison function (as defined in 22.1.3.24) on the set of all Strings.

The actual return values are implementation-defined to permit implementers to encode additional information in the value, but the function is required to define a total ordering on all Strings and to return 0 when comparing Strings that are considered canonically equivalent by the Unicode standard.

If no language-sensitive comparison at all is available from the host environment, this function may perform a bitwise comparison.

NOTE 1 The `localeCompare` method itself is not directly suitable as an argument to `Array.prototype.sort` because the latter requires a function of two arguments.

NOTE 2 This function is intended to rely on whatever language-sensitive comparison functionality is available to the ECMA-Script environment from the host environment, and to compare according to the rules of the host environment’s current locale. It is strongly recommended that this function treat Strings that are canonically equivalent according to the Unicode standard as identical (in other words, compare the Strings as if they had both been converted to Normalised Form C or D first). It is also recommended that this function not honour Unicode compatibility equivalences or decompositions.

NOTE 3 The second parameter to this function is likely to be used in a future version of this standard; it is recommended that implementations do not use this parameter position for anything else.

NOTE 4 The `localeCompare` function is intentionally generic; it does not require that its `this` value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.11 `String.prototype.match (regexp)`

When the `match` method is called with argument `regexp`, the following steps are taken:

1. Let `O` be `CheckObjectCoercible(this value).
2. Let `S` be `ToString(O).
3. ReturnIfAbrupt(S).
4. If Type(regexp) is Object and HasProperty(regexp, @@isRegExp) is true, then let `rx` be `regexp`.
5. Else, let `rx` be the result of the abstract operation `RegExpCreate` (21.2.3.3) with arguments `regexp` and `undefined`.
6. ReturnIfAbrupt(rx).
7. Return the result of `Invoke(rx, "match", (S)).`

NOTE The `match` function is intentionally generic; it does not require that its `this` value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.12 `String.prototype.normalize (form = "NFC")`

When the `normalize` method is called with one argument `form`, the following steps are taken:

1. Let `O` be `CheckObjectCoercible(this value).
2. Let `S` be `ToString(O).
3. ReturnIfAbrupt(S).
4. If `form` is not provided or `undefined` let `form` be "NFC".
5. Let `f` be `ToString(form).
6. ReturnIfAbrupt(f).
7. If `f` is not one of "NFC", "NFD", "NFKC", or "NFKD", then throw a `RangeError` Exception.
8. Let `ns` be the String value is the result of normalizing `S` into the normalization form named by `f` as specified in `http://www.unicode.org/reports/tr15/tr15-29.html`.
9. Return `ns`.

NOTE The `normalize` function is intentionally generic; it does not require that its `this` value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.
21.1.3.13 String.prototype.repeat (count)

The following steps are taken:

1. Let O be CheckObjectCoercible(this value).
2. Let S be ToString(O).
3. ReturnIfAbrupt(S).
4. Let n be the result of calling ToInteger(count).
5. ReturnIfAbrupt(n).
6. If n < 0, then throw a RangeError exception.
7. If n is +\infty, then throw a RangeError exception.
8. Let T be a String value that is made from n copies of S appended together. If n is 0, T is the empty String.
9. Return T.

NOTE 1 This method creates a String consisting of the string elements of this object (converted to String) repeated count time.

NOTE 2 The repeat function is intentionally generic; it does not require that its this value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.14 String.prototype.replace (searchValue, replaceValue)

When the replace method is called with argument searchValue and replaceValue the following steps are taken:

1. Let O be CheckObjectCoercible(this value).
2. Let string be ToString(O).
3. ReturnIfAbrupt(string).
4. If Type(searchValue) is Object and HasProperty(searchValue, @@isRegExp) is true, then
   a. Return the result of Invoke(searchValue, "replace", (string, replaceValue)).
5. Let searchString be ToString(searchValue).
6. ReturnIfAbrupt(searchString).
7. Search string for the first occurrence of searchString and let pos be the index position within string of the first code unit of the matched substring and let matched be searchString. If no occurrences of searchString were found, return string.
8. If IsCallable(replaceValue) is true, then
   a. Let replValue be the result of calling the [[Call]] internal method of replaceValue passing undefined as the this value and a List containing matched, pos, and string as the argument list.
   b. Let replStr be ToString(replValue).
   c. ReturnIfAbrupt(replStr).
9. Else,
   a. Let captures be an empty List.
   b. Let replStr be the result of the abstract operation GetReplaceSubstitution(matched, string, pos, captures).
10. Let tailPos be pos + the number of code units in matched.
11. Let newString be the String formed by concatenating the first pos code units of string, replStr, and the trailing substring of string starting at index tailPos. If pos is 0, the first element of the concatenation will be the empty String.
12. Return newString.

NOTE The replace function is intentionally generic; it does not require that its this value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

Runtime Semantics: GetReplaceSubstitution Abstract Operation

The abstract operation GetReplaceSubstitution(matched, string, position, captures) performs the following steps:

1. Assert: Type(matched) is String.
2. Let matchLength be the number of code units in matched.
3. Assert: Type(string) is String.
4. Let `stringLength` be the number of code units in `string`.
5. Assert: `position` is a non-negative integer.
7. Assert: `captures` is a possibly empty List of Strings.
8. Let `tailPos` be `position + matchLength`.
9. Let `m` be the number of elements in `captures`.
10. Let `result` be a String value derived from `matched` by replacing code unit elements in `matched` by replacement text as specified in Table 33. These $ replacements are done left-to-right, and, once such a replacement is performed, the new replacement text is not subject to further replacements.
11. Return `result`.

21.1.3.15 `String.prototype.search (regexp)`

When the search method is called with argument `regexp`, the following steps are taken:

1. Let `O` be `CheckObjectCoercible(this value)`.
2. Let `string` be `ToString(O)`.
3. ReturnIfAbrupt(`string`).
4. If `Type(regexp)` is `Object` and HasProperty(`regexp`, `@@isRegExp`) is `true`, then,
   a. Let `rx` be `regexp`.
   b. Else, let `rx` be the result of the abstract operation `RegExpCreate (21.2.3.3)` with arguments `regexp` and `undefined`.
5. ReturnIfAbrupt(`rx`).
6. Return the result of `Invoke(rx, "search", (string))`.

NOTE The `search` function is intentionally generic; it does not require that its `this` value be a `String` object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.16 `String.prototype.slice (start, end)`

The `slice` method takes two arguments, `start` and `end`, and returns a substring of the result of converting this object to a `String`, starting from element position `start` and running to, but not including, element position `end` (or through the end of the `String` if `end` is `undefined`). If `start` is negative, it is treated as `sourceLength + start` where `sourceLength` is the length of the `String`. If `end` is negative, it is treated as `sourceLength + end` where...
`sourceLength` is the length of the String. The result is a String value, not a String object. The following steps are taken:

1. Let `O` be `CheckObjectCoercible(this value)`.
2. Let `S` be `ToString(O)`.
3. ReturnIfAbrupt(S).
4. Let `len` be the number of elements in `S`.
5. Let `intStart` be `ToInteger(start)`.
6. If `end is undefined`, let `intEnd` be `len`; else let `intEnd` be `ToInteger(end)`.
7. If `intStart` is negative, let `from` be `max(len + intStart, 0)`; else let `from` be `intStart`.
8. If `intEnd` is negative, let `to` be `max(len + intEnd, 0)`; else let `to` be `min(intEnd, len)`.
9. Let `span` be `max(to – from, 0)`.
10. Return a String value containing `span` consecutive elements from `S` beginning with the element at position `from`.

The `length` property of the `slice` method is 2.

NOTE The `slice` function is intentionally generic; it does not require that its `this` value be a String object. Therefore it can be transferred to other kinds of objects for use as a method.

21.1.3.17 String.prototype.split (separator, limit)

Returns an Array object into which substrings of the result of converting this object to a String have been stored. The substrings are determined by searching from left to right for occurrences of `separator`; these occurrences are not part of any substring in the returned array, but serve to divide up the String value. The value of `separator` may be a String of any length or it may be a RegExp object.

The value of `separator` may be an empty String, an empty regular expression, or a regular expression that can match an empty String. In this case, `separator` does not match the empty substring at the beginning or end of the input String, nor does it match the empty substring at the end of the previous separator match. (For example, if `separator` is the empty String, the String is split up into individual code unit elements; the length of the returned array equals the length of the String, and each substring contains one code unit.) If `separator` is a regular expression, only the first match at a given position of the this String is considered, even if backtracking could yield a non-empty substring match at that position. (For example, "ab".split(/a*?/) evaluates to the array ["a", "b"], while "ab".split(/a+/) evaluates to the array ["", "b"].)

If the `this` object is (or converts to) the empty String, the result depends on whether `separator` can match the empty String. It is, if the result array contains no elements. Otherwise, the result array contains one element, which is the empty String.

If `separator` is a regular expression that contains capturing parentheses, then each time `separator` is matched the results (including any `undefined` results) of the capturing parentheses are spliced into the output array. For example:

```
"A\<B\ And\ CODE\ coded\</CODE\>\"\s+\.<\s+/>\)?\(\^\s+>\)?\)/
```

evaluates to the array

```
```

If `separator` is `undefined`, then the result array contains just one String, which is the `this` value (converted to a String). If `limit` is not `undefined`, then the output array is truncated so that it contains no more than `limit` elements.

When the `split` method is called, the following steps are taken:

1. Let `O` be `CheckObjectCoercible(this value)`.
2. ReturnIfAbrupt(O).
3. If Type(separator) is Object and HasProperty(separator, @@isRegExp) is true, then:
   a. Return the result of Invoke(separator, "split", (O, limit))
4. Let $S$ be ToString($O$).
5. ReturnIfAbrupt($S$).
6. Let $A$ be the result of the abstract operation ArrayCreate with argument 0.
7. Let $\text{lengthA}$ be 0.
8. If $\text{limit}$ is undefined, let $\text{lim} = 2^{32} - 1$; else let $\text{lim} = \text{ToUint32}(\text{limit})$.
9. Let $s$ be the number of elements in $S$.
10. Let $p = 0$.
11. Let $R$ be ToString($\text{separator}$).
12. ReturnIfAbrupt($R$).
13. If $\text{lim} = 0$, return $A$.
14. If $\text{separator}$ is undefined, then
   a. Let $\text{status}$ be the result of calling the [[DefineOwnProperty]] internal method of $A$ with arguments
      *$0^*$ and Property Descriptor {
      [[Value]]: $S$, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}.
   b. Assert: $\text{status}$ is not an abrupt completion.
   c. Return $A$.
15. If $s = 0$, then
   a. Let $q$ be the result of SplitMatch($S$, 0, $R$).
   b. If $q$ is not false, return $A$.
   c. Let $\text{status}$ be the result of calling the [[DefineOwnProperty]] internal method of $A$ with arguments
      *$0^*$ and Property Descriptor {
      [[Value]]: $S$, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}.
   d. Assert: $\text{status}$ is not an abrupt completion.
   e. Return $A$.
16. Let $q = p$.
17. Repeat, while $q \neq s$
   a. Let $r$ be the result of SplitMatch($S$, $q$, $R$).
   b. If $r$ is false, then let $q = q + 1$.
   c. Else $r$ is an integer index into $S$.
      i. If $r = p$, then let $q = q + 1$.
      ii. Else $r$ is $p$.
         1. Let $T$ be a String value equal to the substring of $S$ consisting of the code units at
            positions $p$ (inclusive) through $q$ (exclusive).
         2. Let $\text{status}$ be the result of calling the [[DefineOwnProperty]] internal method of $A$
            with arguments ToString($\text{lengthA}$) and Property Descriptor {
            [[Value]]: $T$, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}.
         3. Assert: $\text{status}$ is not an abrupt completion.
         4. Increment $\text{lengthA}$ by 1.
         5. If $\text{lengthA} = \text{lim}$, return $A$.
         7. Let $q = p$.
18. Let $T$ be a String value equal to the substring of $S$ consisting of the code units
     at positions $p$ (inclusive) through $s$ (exclusive).
19. Let $\text{status}$ be the result of calling the [[DefineOwnProperty]] internal method of $A$ with arguments
     ToString($\text{lengthA}$) and Property Descriptor {
     [[Value]]: $T$, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}.
20. $\text{status}$ is not an abrupt completion.

**Runtime Semantics: SplitMatch Abstract Operation**

The abstract operation SplitMatch takes three parameters, a String $S$, an integer $q$, and a String $R$, and
performs the following in order to return either false or the end index of a match:

1. Type($R$) must be String. Let $r$ be the number of code units in $R$.
2. Let $s$ be the number of code units in $S$.
3. If $q + r > s$ then return false.
4. If there exists an integer $i$ between 0 (inclusive) and $r$ (exclusive) such that the code unit at position $q + i$ of $S$
   is different from the code unit at position $i$ of $R$, then return false.
5. Return q+r.

The length property of the split method is 2.

NOTE The split function is intentionally generic; it does not require that its this value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.18 String.prototype.startsWith (searchString [, position ])

The following steps are taken:

1. Let O be CheckObjectCoercible(this value).
2. Let S be ToString(O).
3. ReturnIfAbrupt(S).
4. Let searchString be ToString(searchString).
5. ReturnIfAbrupt(searchString).
6. Let pos be ToInteger(position). (If position is undefined, this step produces the value 0).
7. ReturnIfAbrupt(pos).
8. Let len be the number of elements in S.
9. Let start be min(max(pos, 0), len).
10. Let searchLength be the number of elements in searchString.
11. If searchLength + start is greater than len, return false.
12. If the searchLength sequence of elements of S starting at start is the same as the full element sequence of searchString, return true.
13. Otherwise, return false.

The length property of the startsWith method is 1.

NOTE 1 This method returns true if the sequence of elements of searchString converted to a String is the same as the corresponding elements of this object (converted to a String) starting at position. Otherwise returns false.

NOTE 2 The startsWith function is intentionally generic; it does not require that its this value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.19 String.prototype.substring (start, end)

The substring method takes two arguments, start and end, and returns a substring of the result of converting this object to a String, starting from element position start and running to, but not including, element position end of the String (or through the end of the String is end is undefined). The result is a String value, not a String object.

If either argument is NaN or negative, it is replaced with zero; if either argument is larger than the length of the String, it is replaced with the length of the String.

If start is larger than end, they are swapped.

The following steps are taken:

1. Let O be CheckObjectCoercible(this value).
2. Let S be ToString(O).
3. ReturnIfAbrupt(S).
4. Let len be the number of elements in S.
5. Let intStart be ToInteger(start).
6. If end is undefined, let intEnd be len; else let intEnd be ToInteger(end).
7. Let finalStart be min(max(intStart, 0), len).
8. Let finalEnd be min(max(intEnd, 0), len).
9. Let from be min(finalStart, finalEnd).
10. Let to be max(finalStart, finalEnd).
11. Return a String whose length is to - from, containing code units from S, namely the code units with indices from through to ~1, in ascending order.
The `length` property of the `substring` method is 2.

**NOTE** The `substring` function is intentionally generic; it does not require that its `this` value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

### 21.1.3.20 `String.prototype.toLocaleLowerCase()`

This function interprets a string value as a sequence of code points, as described in 6.1.4.

This function works exactly the same as `toLowerCase` except that its result is intended to yield the correct result for the host environment's current locale, rather than a locale-independent result. There will only be a difference in the few cases (such as Turkish) where the rules for that language conflict with the regular Unicode case mappings.

**NOTE 1** The first parameter to this function is likely to be used in a future version of this standard; it is recommended that implementations do not use this parameter position for anything else.

**NOTE 2** The `toLocaleLowerCase` function is intentionally generic; it does not require that its `this` value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

### 21.1.3.21 `String.prototype.toLocaleUpperCase()`

This function interprets a string value as a sequence of code points, as described in 6.1.4.

This function works exactly the same as `toUpperCase` except that its result is intended to yield the correct result for the host environment's current locale, rather than a locale-independent result. There will only be a difference in the few cases (such as Turkish) where the rules for that language conflict with the regular Unicode case mappings.

**NOTE 1** The first parameter to this function is likely to be used in a future version of this standard; it is recommended that implementations do not use this parameter position for anything else.

**NOTE 2** The `toLocaleUpperCase` function is intentionally generic; it does not require that its `this` value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

### 21.1.3.22 `String.prototype.toLowerCase()`

This function interprets a string value as a sequence of code points, as described in 6.1.4. The following steps are taken:

1. Let `O` be `CheckObjectCoercible(this value)`.
2. Let `S` be `ToString(O)`.
3. ReturnIfAbrupt(`S`).
4. Let `cpList` be a List containing in order the code points as defined in 6.1.4 of `S`, starting at the first element of `S`.
5. For each code point `c` in `cpList`, if the Unicode Character Database provides a language insensitive lower case equivalent of `c` then replace `c` in `cpList` with that equivalent code point(s).
6. Let `cuList` be a new List.
7. For each code point `c` in `cpList`, in order, append to `cuList` the elements of the UTF-16 Encoding (clause 6) of `c`.
8. Let `L` be a String whose elements are, in order, the elements of `cuList`.

The result must be derived according to the case mappings in the Unicode character database (this explicitly includes not only the UnicodeData.txt file, but also the SpecialCasings.txt file that accompanies it).

**NOTE 1** The case mapping of some code points may produce multiple code points. In this case the result `String` may not be the same length as the source `String`. Because both `toUpperCase` and `toLowerCase` have context-sensitive behaviour, the functions are not symmetrical. In other words, `s.toUpperCase().toLowerCase()` is not necessarily equal to `s.toLowerCase()`.
**NOTE 2** The `toLowerCase` function is intentionally generic; it does not require that its `this` value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.23 `String.prototype.toString()`

When the `toString` method is called, the following steps are taken:

1. Let `s` be `thisStringValue(this value)`.
2. Return `s`.

**NOTE** For a String object, the `toString` method happens to return the same thing as the `valueOf` method.

21.1.3.24 `String.prototype.toUpperCase()`

This function interprets a string value as a sequence of code points, as described in 6.1.4.

This function behaves in exactly the same way as `String.prototype.toLowerCase`, except that code points are mapped to their uppercase equivalents as specified in the Unicode Character Database.

**NOTE** The `toUpperCase` function is intentionally generic; it does not require that its `this` value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.25 `String.prototype.trim()`

This function interprets a string value as a sequence of code points, as described in 6.1.4.

The following steps are taken:

1. Let `O` be `CheckObjectCoercible(this value)`.
2. Let `S` be `ToString(O)`.
3. ReturnIfAbrupt(`S`).
4. Let `T` be a String value that is a copy of `S` with both leading and trailing white space removed. The definition of white space is the union of `WhiteSpace` and `LineTerminator`. When determining whether a Unicode character is in Unicode general category “Zs”, code unit sequences are interpreted as UTF-16 encoded code point sequences as specified in 6.1.4.
5. Return `T`.

**NOTE** The `trim` function is intentionally generic; it does not require that its `this` value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

21.1.3.26 `String.prototype.valueOf()`

When the `valueOf` method is called, the following steps are taken:

1. Let `s` be `thisStringValue(this value)`.
2. Return `s`.

21.1.4 Properties of String Instances

String instances are String exotic objects and have the internal methods specified for such objects. String instances inherit properties from the String prototype object. String instances also have a `[[StringData]]` internal data property.

String instances have a `length` property, and a set of enumerable properties with integer indexed names.

21.1.4.1 `length`

The number of elements in the String value represented by this String object.
Once a String object is initialised, this property is unchanging. It has the attributes { [Writable]: false, [Enumerable]: false, [Configurable]: false }.

21.2 RegExp (Regular Expression) Objects

A RegExp object contains a regular expression and the associated flags.

NOTE The form and functionality of regular expressions is modelled after the regular expression facility in the Perl 5 programming language.

21.2.1 Patterns

The RegExp constructor applies the following grammar to the input pattern String. An error occurs if the grammar cannot interpret the String as an expansion of Pattern.

21.2.2 Pattern Semantics

A regular expression pattern is converted into an internal procedure using the process described below. An implementation is encouraged to use more efficient algorithms than the ones listed below, as long as the results are the same. The internal procedure is used as the value of a RegExp object’s [[RegExpMatcher]] internal data property.

21.2.2.1 Notation

The descriptions below use the following variables:

- **Input** is the String being matched by the regular expression pattern. The notation `input[n]` means the `n`th character of `input`, where `n` can range between 0 (inclusive) and `InputLength` (exclusive).
- **InputLength** is the number of characters in the `Input` String.
- **NcapturingParens** is the total number of left capturing parentheses (i.e. the total number of times the `Atom :: ( Disjunction )` production is expanded) in the pattern. A left capturing parenthesis is any pattern character that is matched by the `(` terminal of the `Atom :: ( Disjunction )` production.
- **IgnoreCase** is true if the RegExp object’s [[OriginalFlags]] internal data property contains “i” and otherwise is false.
- **Multiline** is true if the RegExp object’s [[OriginalFlags]] internal data property contains “m” and otherwise is false.

Furthermore, the descriptions below use the following internal data structures:

- **A CharSet** is a mathematical set of characters.
- **A State** is an ordered pair `(endIndex, captures)` where `endIndex` is an integer and `captures` is a List of `NcapturingParens` values. States are used to represent partial match states in the regular expression matching algorithms. The `endIndex` is one plus the index of the last input character matched so far by the pattern, while `captures` holds the results of capturing parentheses. The `n`th element of `captures` is either a String that represents the value obtained by the `n`th set of capturing parentheses or `undefined` if the `n`th set of capturing parentheses hasn’t been reached yet. Due to backtracking, many States may be in use at any time during the matching process.
- **A MatchResult** is either a State or the special token `failure` that indicates that the match failed.
- **A Continuation** procedure is an internal closure (i.e. an internal procedure with some arguments already bound to values) that takes one State argument and returns a MatchResult result. If an internal closure references variables bound in the function that creates the closure, the closure uses the values that these variables had at the time the closure was created. The Continuation attempts to match the remaining portion (specified by the closure’s already-bound arguments) of the pattern against the input String, starting at the intermediate state given by its State argument. If the match succeeds, the Continuation returns the final State that it reached; if the match fails, the Continuation returns failure.
- **A Matcher** procedure is an internal closure that takes two arguments -- a State and a Continuation -- and returns a MatchResult result. A Matcher attempts to match a middle subpattern (specified by the closure’s already-bound arguments) of the pattern against the input String, starting at the intermediate state given by its State argument. The Continuation argument should be a closure that matches the rest of the pattern. After matching the subpattern of a pattern to obtain a new State, the Matcher then calls Continuation on that new State to test if the rest of the pattern can match as well. If it can, the Matcher returns the State returned by Continuation; if not, the Matcher may try different choices at its choice points, repeatedly calling Continuation until it either succeeds or all possibilities have been exhausted.
• An **AssertionTester** procedure is an internal closure that takes a **State** argument and returns a Boolean result. The assertion tester tests a specific condition (specified by the closure’s already-bound arguments) against the current place in the input String and returns `true` if the condition matched or `false` if not.

• An **EscapeValue** is either a character or an integer. An **EscapeValue** is used to denote the interpretation of a DecimalEscape escape sequence: a character `ch` means that the escape sequence is interpreted as the character `ch`, while an integer `n` means that the escape sequence is interpreted as a backreference to the `n`th set of capturing parentheses.

### 21.2.2 Pattern

The production **Pattern** :: **Disjunction** evaluates as follows:

1. Evaluate **Disjunction** to obtain a Matcher `m`.
2. Return an internal closure that takes two arguments, a String `str` and an integer `index`, and performs the following:
   1. Let `Input` be the given String `str`. This variable will be used throughout the algorithms in 21.2.2.
   2. Let `InputLength` be the length of `Input`. This variable will be used throughout the algorithms in 21.2.2.
   3. Let `c` be a Continuation that always returns its State argument as a successful MatchResult.
   4. Let `cap` be a List of `NcapturingParens` undefined values, indexed 1 through `NcapturingParens`.
   5. Let `x` be the State (index, `cap`).
   6. Call `m(x, c)` and return its result.

**NOTE** A Pattern evaluates (“compiles”) to an internal procedure value. `RegExp.prototype.exec` can then apply this procedure to a String and an offset within the String to determine whether the pattern would match starting at exactly that offset within the String, and, if it does match, what the values of the capturing parentheses would be. The algorithms in 21.2.2 are designed so that compiling a pattern may throw a `SyntaxError` exception; on the other hand, once the pattern is successfully compiled, applying its result internal procedure to find a match in a String cannot throw an exception (except for any host-defined exceptions that can occur anywhere such as out-of-memory).

### 21.2.2.3 Disjunction

The production **Disjunction** :: **Alternative** | **Disjunction** evaluates as follows:

1. Evaluate **Alternative** to obtain a Matcher `m1`.
2. Evaluate **Disjunction** to obtain a Matcher `m2`.
3. Return an internal Matcher closure that takes two arguments, a State `x` and a Continuation `c`, and performs the following:
   1. Call `m1(x, c)` and let `r` be its result.
   2. If `r` isn’t `failure`, return `r`.
   3. Call `m2(x, c)` and return its result.

**NOTE** The | regular expression operator separates two alternatives. The pattern first tries to match the left **Alternative** (followed by the sequel of the regular expression); if it fails, it tries to match the right **Disjunction** (followed by the sequel of the regular expression). If the left **Alternative**, the right **Disjunction**, and the sequel all have choice points, all choices in the sequel are tried before moving on to the next choice in the left **Alternative**. If choices in the left **Alternative** are exhausted, the right **Disjunction** is tried instead of the left **Alternative**. Any capturing parentheses inside a portion of the pattern skipped by | produce undefined values instead of Strings. Thus, for example,

```javascript
/a|ab/.exec("abc")
```

returns the result "a" and not "ab". Moreover,

```javascript
/(a){0}(ab){0}(c){0}(bc){0}.exec("abc")
```

returns the array `"abc", "a", "a", undefined, "bc", undefined, "bc"`
and not

```javascript
["abc", "ab", undefined, "ab", "c", "c", undefined]
```

### 21.2.2.4 Alternative

The production `Alternative :: [empty]` evaluates by returning a Matcher that takes two arguments, a `State x` and a `Continuation c`, and returns the result of calling `c(x)`.

The production `Alternative :: Alternative Term` evaluates as follows:

1. Evaluate `Alternative` to obtain a Matcher `m1`.
2. Evaluate `Term` to obtain a Matcher `m2`.
3. Return an internal Matcher closure that takes two arguments, a `State x` and a `Continuation c`, and returns the result of calling `c(x)`.

**NOTE**

Consecutive `Terms` try to simultaneously match consecutive portions of the input String. If the left `Alternative`, the right `Term`, and the sequel of the regular expression all have choice points, all choices in the sequel are tried before moving on to the next choice in the right `Term`, and all choices in the right `Term` are tried before moving on to the next choice in the left `Alternative`.

### 21.2.2.5 Term

The production `Term :: Assertion` evaluates by returning an internal Matcher closure that takes two arguments, a `State x` and a `Continuation c`, and performs the following:

1. Evaluate `Assertion` to obtain an `AssertionTester t`.
2. Call `t(x)` and let `r` be the resulting Boolean value.
3. If `r` is `false`, return `failure`.
4. Call `c(x)` and return its result.

The production `Term :: Atom` evaluates by evaluating `Atom` to obtain a Matcher and returning that Matcher.

The production `Term :: Atom Quantifier` evaluates as follows:

1. Evaluate `Atom` to obtain a Matcher `m`.
2. Evaluate `Quantifier` to obtain the three results: an integer `min`, an integer (or `∞`) `max`, and Boolean `greedy`.
3. If `max` is finite and less than `min`, then throw a `SyntaxError` exception.
4. Let `parenIndex` be the number of left capturing parentheses in the entire regular expression that occur to the left of this production expansion's `Term`. This is the total number of times the `Atom :: ( Disjunction )` production is expanded plus the total number of `Atom :: ( Disjunction )` productions enclosing this `Term`.
5. Let `parenCount` be the number of left capturing parentheses in the expansion of this production's `Atom`. This is the total number of `Atom :: ( Disjunction )` productions enclosed by this production's `Atom`.
6. Return an internal Matcher closure that takes two arguments, a `State x` and a `Continuation c`, and performs the following:

   1. Call `RepeatMatcher(m, min, max, greedy, x, c, parenIndex, parenCount)` and return its result.

**Runtime Semantics: RepeatMatcher Abstract Operation**

The abstract operation `RepeatMatcher` takes eight parameters, a Matcher `m`, an integer `min`, an integer (or `∞`) `max`, a Boolean `greedy`, a State `x`, a Continuation `c`, an integer `parenIndex`, and an integer `parenCount`, and performs the following:

1. If `max` is zero, then call `c(x)` and return its result.
2. Create an internal Continuation closure `d` that takes one State argument `y` and performs the following:

   1. If `min` is zero and `y's endIndex` is equal to `x's endIndex`, then return `failure`.
   2. If `min` is zero then let `min2` be zero, otherwise let `min2` be `min-1`.
3. If max is \(\infty\), then let max2 be \(\infty\); otherwise let max2 be max – 1.
4. Call RepeatMatcher(m, min2, max2, greedy, y, c, parenIndex, parenCount) and return its result.

Let \(c\) be a fresh copy of \(x\)'s captures List.

For every integer \(k\) that satisfies \(\text{parenIndex} < k\) and \(k \leq \text{parenIndex} + \text{parenCount}\), set \(c[k]\) to undefined.

Let \(e\) be \(x\)'s endIndex.

Let \(xr\) be the State (\(e, c\)).

If \(min\) is not zero, then call \(m(xr, d)\) and return its result.

If \(greedy\) is false, then
   a. Call \(c()\) and let \(z\) be its result.
   b. If \(z\) is not failure, return \(z\).
   c. Call \(m(xr, d)\) and let \(z\) be its result.

10. If \(z\) is not failure, return \(z\).

11. Call \(c()\) and return its result.

**NOTE 1** An Atom followed by a Quantifier is repeated the number of times specified by the Quantifier. A Quantifier can be non-greedy, in which case the Atom pattern is repeated as few times as possible while still matching the sequel, or it can be greedy, in which case the Atom pattern is repeated as many times as possible while still matching the sequel. The Atom pattern is repeated rather than the input String that it matches, so different repetitions of the Atom can match different input substrings.

**NOTE 2** If the Atom and the sequel of the regular expression all have choice points, the Atom is first matched as many (or as few, if non-greedy) times as possible. All choices in the sequel are tried before moving on to the next choice in the last repetition of Atom. All choices in the last (\(n\)) repetition of Atom are tried before moving on to the next choice in the next-to-last (\(n-1\)) repetition of Atom, at which point it may turn out that more or fewer repetitions of Atom are now possible; these are exhausted (again, starting with either as few or as many as possible) before moving on to the next choice in the (\(n-1\)) repetition of Atom and so on.

Compare
   
   \(/a[a-z]{2,4}/.exec("abcdefghi")
   
which returns "abcde" with
   
   \(/a[a-z]{2,4}/.exec("abcdefghi")
   
which returns "abc".

Consider also
   
   \(/(aa|aabaac|ba|b|c)*/.exec("aabaaac")
   
which, by the choice point ordering above, returns the array
   
   
   
   
   

and not any of
   
   
   
   
   
   
   
   

The above ordering of choice points can be used to write a regular expression that calculates the greatest common divisor of two numbers (represented in unary notation). The following example calculates the gcd of 10 and 15:

"aaaaaaaaaa,aaaaaaaaaaaaaaa".replace(/^(a+).1*,$/1+$/,"$1")

which returns the gcd in unary notation "aaaaaa".

**NOTE 3** Step 4 of the RepeatMatcher clears Atom's captures each time Atom is repeated. We can see its behaviour in the regular expression

\(/\((a+)?(b+)?(c+)\)*/.exec("zaacbbbcac")

which returns the array

   
   
   
   

and not

   
   
   
   

because each iteration of the outermost * clears all captured Strings contained in the quantified Atom, which in this case includes capture Strings numbered 2, 3, 4, and 5.
NOTE 4  Step 1 of the RepeatMatcher’s \$ closure states that, once the minimum number of repetitions has been satisfied, any more expansions of Atom that match the empty String are not considered for further repetitions. This prevents the regular expression engine from falling into an infinite loop on patterns such as:

\[(a*)\]/.exec("b")

or the slightly more complicated:

\[(a*)b\]/.exec("aaaaac")

which returns the array

\[ ["b", "]" ] \]

21.2.2.6 Assertion

The production Assertion :: ^ evaluates by returning an internal AssertionTester closure that takes a State argument \( x \) and performs the following:

1. Let \( e \) be \( x \)'s endIndex.
2. If \( e \) is zero, return true.
3. If Multiline is false, return false.
4. If the character Input[\( e-1 \)] is one of LineTerminator, return true.
5. Return false.

The production Assertion :: $ evaluates by returning an internal AssertionTester closure that takes a State argument \( x \) and performs the following:

1. Let \( e \) be \( x \)'s endIndex.
2. If \( e \) is equal to InputLength, return true.
3. If Multiline is false, return false.
4. If the character Input[\( e \)] is one of LineTerminator, return true.
5. Return false.

The production Assertion :: \b evaluates by returning an internal AssertionTester closure that takes a State argument \( x \) and performs the following:

1. Let \( e \) be \( x \)'s endIndex.
2. Call IsWordChar(\( e-1 \)) and let \( a \) be the Boolean result.
3. Call IsWordChar(\( e \)) and let \( b \) be the Boolean result.
4. If \( a \) is true and \( b \) is false, return true.
5. If \( a \) is false and \( b \) is true, return true.
6. Return false.

The production Assertion :: \B evaluates by returning an internal AssertionTester closure that takes a State argument \( x \) and performs the following:

1. Let \( e \) be \( x \)'s endIndex.
2. Call IsWordChar(\( e-1 \)) and let \( a \) be the Boolean result.
3. Call IsWordChar(\( e \)) and let \( b \) be the Boolean result.
4. If \( a \) is true and \( b \) is false, return false.
5. If \( a \) is false and \( b \) is true, return false.
6. Return true.

The production Asserti on :: ( ? = Disjunction ) evaluates as follows:

1. Evaluate Disjunction to obtain a Matcher \( m \).
2. Return an internal Matcher closure that takes two arguments, a State \( x \) and a Continuation \( c \), and performs the following steps:
   1. Let \( d \) be a Continuation that always returns its State argument as a successful MatchResult.
   2. Call \( m(x, d) \) and let \( r \) be its result.
   3. If \( r \) is failure, return failure.
   4. Let \( y \) be \( r \)'s State.
   5. Let \( cap \) be \( y \)'s captures List.
6. Let $x$ be $x$'s endIndex.
7. Let $z$ be the State ($x$, $cap$).
8. Call $c(z)$ and return its result.

The production `Assertion :: ( ? ! Disjunction )` evaluates as follows:

1. Evaluate `Disjunction` to obtain a Matcher $m$.
2. Return an internal Matcher closure that takes two arguments, a State $x$ and a Continuation $c$, and performs the following steps:
   1. Let $d$ be a Continuation that always returns its State argument as a successful MatchResult.
   2. Call $m(x, d)$ and let $r$ be its result.
   3. If $r$ isn't `failure`, return `failure`.
   4. Call $c(x)$ and return its result.

Runtime Semantics: `IsWordChar` Abstract Operation

The abstract operation `IsWordChar` takes an integer parameter $e$ and performs the following:

1. If $e$ is $–1$ or $e$ is `InputLength`, return `false`.
2. Let $c$ be the character `Input[e]`.
3. If $c$ is one of the sixty-three characters below, return `true`.
   \[ a \ b \ c \ d \ e \ f \ g \ h \ i \ j \ k \ l \ m \ n \ o \ p \ q \ r \ s \ t \ u \ v \ w \ x \ y \ z \ A \ B \ C \ D \ E \ F \ G \ H \ I \ J \ K \ L \ M \ N \ O \ P \ Q \ R \ S \ T \ U \ V \ W \ X \ Y \ Z \ 0 \ 1 \ 2 \ 3 \ 4 \ 5 \ 6 \ 7 \ 8 \ 9 \ _ \]
4. Return `false`.

21.2.2.7 Quantifier

The production `Quantifier :: QuantifierPrefix` evaluates as follows:

1. Evaluate `QuantifierPrefix` to obtain the two results: an integer $min$ and an integer (or $\infty$) $max$.
2. Return the three results $min$, $max$, and `true`.

The production `Quantifier :: QuantifierPrefix ?` evaluates as follows:

1. Evaluate `QuantifierPrefix` to obtain the two results: an integer $min$ and an integer (or $\infty$) $max$.
2. Return the three results $min$, $max$, and `false`.

The production `QuantifierPrefix :: *` evaluates by returning the two results 0 and $\infty$.

The production `QuantifierPrefix :: +` evaluates by returning the two results 1 and $\infty$.

The production `QuantifierPrefix :: ?` evaluates by returning the two results 0 and 1.

The production `QuantifierPrefix :: { DecimalDigits }` evaluates as follows:

1. Let $i$ be the MV of `DecimalDigits` (see 11.8.3).
2. Return the two results $i$ and $i$.

The production `QuantifierPrefix :: { DecimalDigits , }` evaluates as follows:

1. Let $i$ be the MV of `DecimalDigits`.
2. Return the two results $i$ and $\infty$.

The production `QuantifierPrefix :: { DecimalDigits , DecimalDigits }` evaluates as follows:

1. Let $i$ be the MV of the first `DecimalDigits`.
2. Let $j$ be the MV of the second `DecimalDigits`.
3. Return the two results \( i \) and \( j \).

### 21.2.2.8 Atom

The production \( \text{Atom} :: \text{PatternCharacter} \) evaluates as follows:

1. Let \( ch \) be the character represented by \( \text{PatternCharacter} \).
2. Let \( A \) be a one-element CharSet containing the character \( ch \).
3. Call \( \text{CharacterSetMatcher}(A, \text{false}) \) and return its Matcher result.

The production \( \text{Atom} :: . \) evaluates as follows:

1. Let \( A \) be the set of all characters except \( \text{LineTerminator} \).
2. Call \( \text{CharacterSetMatcher}(A, \text{false}) \) and return its Matcher result.

The production \( \text{Atom} :: \backslash \text{AtomEscape} \) evaluates by evaluating \( \text{AtomEscape} \) to obtain a Matcher and returning that Matcher.

The production \( \text{Atom} :: \text{CharacterClass} \) evaluates as follows:

1. Evaluate \( \text{CharacterClass} \) to obtain a CharSet \( A \) and a Boolean \( \text{invert} \).
2. Call \( \text{CharacterSetMatcher}(A, \text{invert}) \) and return its Matcher result.

The production \( \text{Atom} :: ( \text{Disjunction} ) \) evaluates as follows:

1. Evaluate \( \text{Disjunction} \) to obtain a Matcher \( m \).
2. Let \( \text{parenIndex} \) be the number of left capturing parentheses in the entire regular expression that occur to the left of this production expansion's initial left parenthesis. This is the total number of times the \( \text{Atom} :: ( \text{Disjunction} ) \) production is expanded prior to this production's \( \text{Atom} \) plus the total number of \( \text{Atom} :: ( \text{Disjunction} ) \) productions enclosing this \( \text{Atom} \).
3. Return an internal Matcher closure that takes two arguments, a State \( x \) and a Continuation \( c \), and performs the following steps:
   1. Create an internal Continuation closure \( d \) that takes one State argument \( y \) and performs the following steps:
      1. Let \( \text{cap} \) be a fresh copy of \( y \)'s captures List.
      2. Let \( xe \) be \( x \)'s \( \text{endIndex} \).
      3. Let \( ye \) be \( y \)'s \( \text{endIndex} \).
      4. Let \( s \) be a fresh String whose characters are the characters of \( \text{Input} \) at positions \( xe \) (inclusive) through \( ye \) (exclusive).
      5. Set \( \text{cap}[\text{parenIndex}\!+\!1] \) to \( s \).
      6. Let \( z \) be the State \( (ye, \text{cap}) \).
      7. Call \( c(z) \) and return its result.
   2. Call \( m(x, d) \) and return its result.

The production \( \text{Atom} :: ( ? : \text{Disjunction} ) \) evaluates by evaluating \( \text{Disjunction} \) to obtain a Matcher and returning that Matcher.

**Runtime Semantics: CharacterSetMatcher Abstract Operation**

The abstract operation \( \text{CharacterSetMatcher} \) takes two arguments, a CharSet \( A \) and a Boolean flag \( \text{invert} \), and performs the following:

1. Return an internal Matcher closure that takes two arguments, a State \( x \) and a Continuation \( c \), and performs the following steps:
   1. Let \( e \) be \( x \)'s \( \text{endIndex} \).
   2. If \( e \) is \( \text{InputLength} \), return \text{failure}.
   3. Let \( ch \) be the character \( \text{Input}(e) \).
   4. Let \( cb \) be the result of \( \text{Canonicalize}(ch) \).
   5. If \( \text{invert} \) is \text{false}, then
a If there does not exist a member \( a \) of set \( A \) such that Canonicalize\( (a) \) is \( cc \), return failure.

6. Else invert is true.
   a If there exists a member \( a \) of set \( A \) such that Canonicalize\( (a) \) is \( cc \), return failure.

7. Let \( cap \) be \( a \)'s captures List.
8. Let \( y \) be the State \( (e+1, cap) \).
9. Call \( c(y) \) and return its result.

Runtime Semantics: Canonicalize Abstract Operation

The abstract operation Canonicalize takes a character parameter \( ch \) and performs the following steps:

1. If IgnoreCase is false, return \( ch \).
2. Let \( u \) be \( ch \) converted to upper case as if by calling the standard built-in method String.prototype.toUpperCase on the one-character String \( ch \).
3. If \( u \) does not consist of a single character, return \( ch \).
4. Let \( cu \) be \( u \)'s character.
5. If \( ch \)'s code unit value is greater than or equal to decimal 128 and \( cu \)'s code unit value is less than decimal 128, then return \( ch \).
6. Return \( cu \).

NOTE 1 Parentheses of the form \( \{ \text{Disjunction} \} \) serve both to group the components of the Disjunction pattern together and to save the result of the match. The result can be used either in a backreference \( (\cdot) \) followed by a nonzero decimal number), referenced in a replace String, or returned as part of an array from the regular expression matching internal procedure. To inhibit the capturing behaviour of parentheses, use the form \( (?: \text{Disjunction}) \) instead.

NOTE 2 The form \( (?= \text{Disjunction}) \) specifies a zero-width positive lookahead. In order for it to succeed, the pattern inside Disjunction must match at the current position, but the current position is not advanced before matching the sequel. If Disjunction can match at the current position in several ways, only the first one is tried. Unlike other regular expression operators, there is no backtracking into a \( (?= \) form (this unusual behaviour is inherited from Perl). This only matters when the Disjunction contains capturing parentheses and the sequel of the pattern contains backreferences to those captures.

For example,

\[
(/(?=(a+))/.exec("baaabac")
\]

matches the empty String immediately after the first \( b \) and therefore returns the array:

\[
["", "aaa"]
\]

To illustrate the lack of backtracking into the lookahead, consider:

\[
(/(?=(a+))a*b\1/.exec("baaabac")
\]

This expression returns:

\[
["aba", "a"]
\]

and not:

\[
["aaaba", "a"]
\]

NOTE 3 The form \( (?! \text{Disjunction}) \) specifies a zero-width negative lookahead. In order for it to succeed, the pattern inside Disjunction must fail to match at the current position. The current position is not advanced before matching the sequel. Disjunction can contain capturing parentheses, but backreferences to them only make sense from within Disjunction itself. Backreferences to these capturing parentheses from elsewhere in the pattern always return undefined because the negative lookahead must fail for the pattern to succeed. For example,

\[
(/(.*)(?!\(a\)+b\1)c/.exec("baaabac"))
\]

looks for an \( a \) not immediately followed by some positive number \( n \) of \( a \)'s, \( a \) \( b \) and another \( n \) \( a \)'s (specified by the first \( \2 \)) and \( a \) \( e \). The second \( \2 \) is outside the negative lookahead, so it matches against undefined and therefore always succeeds.

The whole expression returns the array:

\[
["baaabac", "ba", undefined, "abaec"]
\]

In case-insensitive matches all characters are implicitly converted to upper case immediately before they are compared. However, if converting a character to upper case would expand that character into more than one character (such as converting "ß" \( (\cdot) \) into "SS"), then the character is left as-is instead. The character is also left as-is if it is not an ASCII character but converting it to upper case would make it into an ASCII character. This prevents Unicode characters...
such as \u0131 and \u017F from matching regular expressions such as /\[a-z]/, which are only intended to match ASCII letters. Furthermore, if these conversions were allowed, then /[^\W]/ would match each of a, b, ..., h, but not i or s.

21.2.2.9 AtomEscape

The production AtomEscape :: DecimalEscape evaluates as follows:

1. Evaluate DecimalEscape to obtain an EscapeValue $E$.
2. If $E$ is a character, then
   a. Let $ch$ be $E$'s character.
   b. Let $A$ be a one-element CharSet containing the character $ch$.
   c. Call CharacterSetMatcher($A$, false) and return its Matcher result.
3. $E$ must be an integer. Let $n$ be that integer.
4. If $n=0$ or $n>N_capturingParens$ then throw a SyntaxError exception.
5. Return an internal Matcher closure that takes two arguments, a State $x$ and a Continuation $c$, and performs the following:
   1. Let $cap$ be $x$'s captures List.
   2. Let $s$ be $cap[n]$.
   3. If $s$ is undefined, then call $c(s)$ and return its result.
   4. Let $e$ be $s$'s endIndex.
   5. Let $len$ be $s$'s length.
   6. Let $f$ be $e+len$.
   7. If $f>InputLength$, return failure.
   8. If there exists an integer $i$ between 0 (inclusive) and $len$ (exclusive) such that Canonicalize($s[i]$) is not the same character as Canonicalize(Input[$e+i$]), then return failure.
   9. Let $y$ be the State ($f$, $cap$).
   10. Call $c(y)$ and return its result.

The production AtomEscape :: CharacterEscape evaluates as follows:

1. Evaluate CharacterEscape to obtain a character $ch$.
2. Let $A$ be a one-element CharSet containing the character $ch$.
3. Call CharacterSetMatcher($A$, false) and return its Matcher result.

The production AtomEscape :: CharacterClassEscape evaluates as follows:

1. Evaluate CharacterClassEscape to obtain a CharSet $A$.
2. Call CharacterSetMatcher($A$, false) and return its Matcher result.

NOTE An escape sequence of the form \ followed by a nonzero decimal number $n$ matches the result of the $n$th set of capturing parentheses (see 21.2.2.11). It is an error if the regular expression has fewer than $n$ capturing parentheses. If the regular expression has $n$ or more capturing parentheses but the $n$th one is undefined because it has not captured anything, then the backreference always succeeds.

21.2.2.10 CharacterEscape

The production CharacterEscape :: ControlEscape evaluates by returning the character according to Table 34.

<table>
<thead>
<tr>
<th>ControlEscape</th>
<th>Code Unit</th>
<th>Name</th>
<th>Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>\u0009</td>
<td>horizontal tab</td>
<td>&lt;HT&gt;</td>
</tr>
<tr>
<td>n</td>
<td>\u000A</td>
<td>line feed (new line)</td>
<td>&lt;LF&gt;</td>
</tr>
<tr>
<td>v</td>
<td>\u000B</td>
<td>vertical tab</td>
<td>&lt;VT&gt;</td>
</tr>
<tr>
<td>f</td>
<td>\u000C</td>
<td>form feed</td>
<td>&lt;FF&gt;</td>
</tr>
<tr>
<td>r</td>
<td>\u000D</td>
<td>carriage return</td>
<td>&lt;CR&gt;</td>
</tr>
</tbody>
</table>
The production `CharacterEscape :: c ControlLetter` evaluates as follows:

1. Let `ch` be the character represented by `ControlLetter`.
2. Let `i` be `ch`'s code unit value.
3. Let `j` be the remainder of dividing `i` by 32.
4. Return the character whose code unit value is `j`.

The production `CharacterEscape :: HexEscapeSequence` evaluates by evaluating the CV of the `HexEscapeSequence` (see 11.8.4) and returning its character result.

The production `CharacterEscape :: UnicodeEscapeSequence` evaluates by evaluating the CV of the `UnicodeEscapeSequence` (see 11.8.4) and returning its character result.

The production `CharacterEscape :: IdentityEscape` evaluates by returning the character represented by `IdentityEscape`.

### 21.2.2.11 DecimalEscape

The production `DecimalEscape :: DecimalIntegerLiteral [lookahead \0 DecimalDigit]` evaluates as follows:

1. Let `i` be the MV of `DecimalIntegerLiteral`.
2. If `i` is zero, return the `EscapeValue` consisting of a `<NUL>` character (Unicode value 0000).
3. Return the `EscapeValue` consisting of the integer `i`.

The definition of “the MV of `DecimalIntegerLiteral`” is in 11.8.3.

**NOTE** If `\` is followed by a decimal number whose first digit is not 0, then the escape sequence is considered to be a backreference. It is an error if `n` is greater than the total number of left capturing parentheses in the entire regular expression. \0 represents the `<NUL>` character and cannot be followed by a decimal digit.

### 21.2.2.12 CharacterClassEscape

The production `CharacterClassEscape :: d` evaluates by returning the ten-element set of characters containing the characters 0 through 9 inclusive.

The production `CharacterClassEscape :: D` evaluates by returning the set of all characters not included in the set returned by `CharacterClassEscape :: d`.

The production `CharacterClassEscape :: s` evaluates by returning the set of characters containing the characters that are on the right-hand side of the `WhiteSpace` (11.2) or `LineTerminator` (11.3) productions.

The production `CharacterClassEscape :: S` evaluates by returning the set of all characters not included in the set returned by `CharacterClassEscape :: s`.

The production `CharacterClassEscape :: w` evaluates by returning the set of characters containing the sixty-three characters:

```
  a b c d e f g h i j k l m n o p q r s t u v w x y z
  A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
  0 1 2 3 4 5 6 7 8 9 _
```

The production `CharacterClassEscape :: W` evaluates by returning the set of all characters not included in the set returned by `CharacterClassEscape :: w`.

### 21.2.2.13 CharacterClass

The production `CharacterClass :: [ [lookahead \*] ClassRanges ]` evaluates by evaluating `ClassRanges` to obtain a CharSet and returning that CharSet and the Boolean `false`.
The production `CharacterClass :: [ ^ ClassRanges ]` evaluates by evaluating `ClassRanges` to obtain a CharSet and returning that CharSet and the Boolean `true`.

21.2.2.14 `ClassRanges`

The production `ClassRanges :: [empty]` evaluates by returning the empty CharSet.

The production `ClassRanges :: NonemptyClassRanges` evaluates by evaluating `NonemptyClassRanges` to obtain a CharSet and returning that CharSet.

21.2.2.15 `NonemptyClassRanges`

The production `NonemptyClassRanges :: ClassAtom` evaluates by evaluating `ClassAtom` to obtain a CharSet and returning that CharSet.

The production `NonemptyClassRanges :: ClassAtom NonemptyClassRangesNoDash` evaluates as follows:

1. Evaluate `ClassAtom` to obtain a CharSet `A`.
2. Evaluate `NonemptyClassRangesNoDash` to obtain a CharSet `B`.
3. Return the union of CharSets `A` and `B`.

The production `NonemptyClassRanges :: ClassAtom - ClassAtom ClassRanges` evaluates as follows:

1. Evaluate the first `ClassAtom` to obtain a CharSet `A`.
2. Evaluate the second `ClassAtom` to obtain a CharSet `B`.
3. Evaluate `ClassRanges` to obtain a CharSet `C`.
4. Call `CharacterRange(A, B)` and let `D` be the resulting CharSet.
5. Return the union of CharSets `D` and `C`.

**Runtime Semantics: CharacterRange Abstract Operation**

The abstract operation `CharacterRange` takes two CharSet parameters `A` and `B` and performs the following:

1. If `A` does not contain exactly one character or `B` does not contain exactly one character then throw a `SyntaxError` exception.
2. Let `a` be the one character in CharSet `A`.
3. Let `b` be the one character in CharSet `B`.
4. Let `i` be the code unit value of character `a`.
5. Let `j` be the code unit value of character `b`.
6. If `i > j` then throw a `SyntaxError` exception.
7. Return the set containing all characters numbered `i` through `j`, inclusive.

21.2.2.16 `NonemptyClassRangesNoDash`

The production `NonemptyClassRangesNoDash :: ClassAtom` evaluates by evaluating `ClassAtom` to obtain a CharSet and returning that CharSet.

The production `NonemptyClassRangesNoDash :: ClassAtomNoDash NonemptyClassRangesNoDash` evaluates as follows:

1. Evaluate `ClassAtomNoDash` to obtain a CharSet `A`.
2. Evaluate `NonemptyClassRangesNoDash` to obtain a CharSet `B`.
3. Return the union of CharSets `A` and `B`.

The production `NonemptyClassRangesNoDash :: ClassAtomNoDash - ClassAtom ClassRanges` evaluates as follows:

1. Evaluate `ClassAtomNoDash` to obtain a CharSet `A`.
2. Evaluate `ClassAtom` to obtain a CharSet `B`.
3. Evaluate `ClassRanges` to obtain a CharSet `C`.
4. Call `CharacterRange(A, B)` and let `D` be the resulting CharSet.
5. Return the union of CharSets `D` and `C`.

**NOTE 1** `ClassRanges` can expand into single `ClassAtom` or ranges of two `ClassAtom` separated by dashes. In the latter case the `ClassRanges` includes all characters between the first `ClassAtom` and the second `ClassAtom`, inclusive; an error occurs if either `ClassAtom` does not represent a single character (for example, if one is `\w`) or if the first `ClassAtom`'s code unit value is greater than the second `ClassAtom`'s code unit value.

**NOTE 2** Even if the pattern ignores case, the case of the two ends of a range is significant in determining which characters belong to the range. Thus, for example, the pattern `/[E-F]/i` matches only the letters `E`, `F`, `a`, and `z`, while the pattern `/[e-f]/i` matches all upper and lower-case ASCII letters as well as the symbols `!`, `@`, `#`, `$`, `%`, `^`, `_`, and `.`.

**NOTE 3** A character can be treated literally or it can denote a range. It is treated literally if it is the first or last character of `ClassRanges`, the beginning or end limit of a range specification, or immediately follows a range specification.

### 21.2.2.17 ClassAtom

The production `ClassAtom :: -` evaluates by returning the CharSet containing the one character `-`.

The production `ClassAtom :: ClassAtomNoDash` evaluates by evaluating `ClassAtomNoDash` to obtain a CharSet and returning that CharSet.

### 21.2.2.18 ClassAtomNoDash

The production `ClassAtomNoDash :: SourceCharacter but not one of \ or ] or -` evaluates by returning a one-element CharSet containing the character represented by `SourceCharacter`.

The production `ClassAtomNoDash :: \ ClassEscape` evaluates by evaluating `ClassEscape` to obtain a CharSet and returning that CharSet.

### 21.2.2.19 ClassEscape

The production `ClassEscape :: DecimalEscape` evaluates as follows:

1. Evaluate `DecimalEscape` to obtain an EscapeValue `E`.
2. If `E` is not a character then throw a `SyntaxError` exception.
3. Let `ch` be `E`'s character.
4. Return the one-element CharSet containing the character `ch`.

The production `ClassEscape :: b` evaluates by returning the CharSet containing the one character `<BS>` (Unicode value 0008).

The production `ClassEscape :: CharacterEscape` evaluates by evaluating `CharacterEscape` to obtain a character and returning a one-element CharSet containing that character.

The production `ClassEscape :: CharacterClassEscape` evaluates by evaluating `CharacterClassEscape` to obtain a CharSet and returning that CharSet.

**NOTE** A `ClassAtom` can use any of the escape sequences that are allowed in the rest of the regular expression except for \b, \B, and backreferences. Inside a `CharacterClass`, \b means the backspace character, while \B and backreferences raise errors. Using a backreference inside a `ClassAtom` causes an error.

### 21.2.3 The RegExp Constructor

The RegExp constructor is the `%RegExp%` intrinsic object and the initial value of the `RegExp` property of the global object. When `RegExp` is called as a function rather than as a constructor, it creates and initializes a new RegExp object. Thus the function call `RegExp(\_)` is equivalent to the object creation expression `new RegExp(\_)` with the same arguments. However, if the `this` value passed in the call is an Object.
with an ᵃ[RegExpMatcher] internal data property whose value is undefined, it initialises the this value using the argument values. This permits RegExp to be used both as factory method and to perform constructor instance initialization.

The RegExp constructor is designed to be subclassable. It may be used as the value of an extends clause of a class declaration. Subclass constructors that intended to inherit the specified RegExp behaviour must include a super call to the RegExp constructor to initialise subclass instances.

21.2.3.1 RegExp(pattern, flags)

The following steps are taken:

1. Let func be this RegExp function object.
2. Let O be the this value.
3. If Type(O) is not Object or Type(O) is Object and O does not have a ᵃ[RegExpMatcher] internal data property or Type(O) is Object and O has a ᵃ[RegExpMatcher] internal data property and the value of ᵃ[RegExpMatcher] is not undefined, then
   a. If Type(pattern) is Object and O has a ᵃ[RegExpMatcher] internal data property and flags is undefined, then
      i. Return pattern;
   b. Let O be the result of calling the abstract operation RegExpAlloc with argument func.
   c. ReturnIfAbrupt(O).
4. If Type(pattern) is Object and pattern has a ᵃ[RegExpMatcher] internal data property, then
   a. If the value of pattern’s ᵃ[RegExpMatcher] internal data property is undefined, then throw a TypeError exception.
   b. If flags is not undefined, then throw a TypeError exception.
   c. Let P be the value of pattern’s ᵃ[OriginalSource] internal data property.
   d. Let F be the value of pattern’s ᵃ[OriginalFlags] internal data property.
5. Else,
   a. Let P be pattern.
   b. Let F be flags.
6. Return the result of the abstract operation RegExpInitialise with arguments O, P, and F.

NOTE If pattern is supplied using a StringLiteral, the usual escape sequence substitutions are performed before the String is processed by RegExp. If pattern must contain an escape sequence to be recognised by RegExp, any backslash \ characters must be escaped within the StringLiteral to prevent them being removed when the contents of the StringLiteral are formed.

21.2.3.2 new RegExp(...argumentsList)

RegExp called as part of a new expression with argument list argumentsList if performs the following steps:

1. Let F be the RegExp function object on which the new operator was applied.
2. Let argumentsList be the argumentsList argument of the ᵃ[Construct] internal method that was invoked by the new operator.
3. Return the result of OrdinaryConstruct (F, argumentsList).

If RegExp is implemented as an ordinary function object, its ᵃ[Construct] internal method will perform the above steps.

21.2.3.3 Abstract Operations for the RegExp Constructor

Runtime Semantics: RegExpAlloc Abstract Operation

When the abstract operation RegExpAlloc with argument constructor is called, the following steps are taken:

1. Assert: constructor is an object that has a ᵃ[Construct] internal method.
2. Let obj be the result of calling OrdinaryCreateFromConstructor(constructor, ᵃ RegExpPrototype, ᵃ RegExpPrototype, ᵃ RegExpPrototype).

Commented [AW814137]: This then clause corresponds to the "called as a function" case the ES5 spec.
3. Let status be the result of DefinePropertyOrThrow(obj, "lastIndex", PropertyDescriptor {[[Writable]]: true, [[Enumerable]]: false, [[Configurable]]: false}).

4. ReturnIfAbrupt(status).

5. Return obj.

NOTE [[RegExpMatcher]] is initially assigned the value undefined as a flag to indicate that the instance has not yet been initialised by the RegExp constructor. This flag value is never directly exposed to ECMAScript code; hence implementation may choose to encode the flag in some other manner.

Runtime Semantics: RegExpInitialise Abstract Operation

When the abstract operation RegExpInitialise with arguments obj, pattern, and flags is called, the following steps are taken:

1. If pattern is undefined, then let P be the empty String.
2. Else, let P be ToString(pattern).
3. ReturnIfAbrupt(P).
4. If flags is undefined, then let F be the empty String.
5. Else, let F be ToString(flags).
6. ReturnIfAbrupt(F).
7. If F contains any character other than "g", "i", "m", "u", or "y" or if it contains the same character more than once, then throw a SyntaxError exception.
8. Parse P interpreted as UTF-16 encoded Unicode characters using the grammars in 21.2.1 for the goal symbol Pattern. Throw a SyntaxError exception if P did not conform to the grammar or if all characters of P where not matched by the parse.
9. Set obj's [[RegExpMatcher]] internal data property to the internal procedure obtained by evaluating ("compiling") the step 3’s parse of P and applying the semantics provided in 21.2.2.
10. Set the value of obj's [[OriginalSource]] internal data property to P.
11. Set the value of obj's [[OriginalFlags]] internal data property to F.
12. Let putStatus be the result of Put(obj, "lastIndex", 0, true).
13. ReturnIfAbrupt(putStatus).

Runtime Semantics: RegExpCreate Abstract Operation

When the abstract operation RegExpCreate with arguments P and F is called, the following steps are taken:

1. Let obj be the result of calling the abstract operation RegExpAlloc with argument %RegExp%.
2. ReturnIfAbrupt(obj).
3. Return the result of the abstract operation RegExpInitialise with arguments obj, P, and F.

Runtime Semantics: EscapeRegExpPattern Abstract Operation

When the abstract operation EscapeRegExpPattern with arguments P and F is called, the following occurs:

Let S be a String in the form of a Pattern equivalent to P interpreted as UTF-16 encoded Unicode characters, in which certain characters are escaped as described below. S may or may not be identical to P or pattern; however, the internal procedure that would result from evaluating S as a Pattern must behave identically to the internal procedure given by the constructed object’s [[RegExpMatcher]] internal data property. Separate calls to this abstract operation using the same values for P and F must produce identical results.

The characters / occurring in the pattern shall be escaped in S as necessary to ensure that the String value formed by concatenating the Strings "/", S, "/", and F can be parsed (in an appropriate lexical context) as a RegularExpressionLiteral that behaves identically to the constructed regular expression. For example, if F is "/", then S could be "\//" or "\002//", among other possibilities but not "//", because // followed by F would be parsed as a SingleLineComment rather than a RegularExpressionLiteral. If P is the empty String, this specification can be met by letting S be "(?:)".

Return S.

Commented [AWB141138]: Why is this underspecified? Why not specify an required escaping? Do different implementation differ in their results?
21.2.4 Properties of the RegExp Constructor

The value of the [[Prototype]] internal data property of the RegExp constructor is the standard built-in Function prototype object (19.2.3).

Besides the length property (whose value is 2), the RegExp constructor has the following properties:

21.2.4.1 RegExp.prototype

The initial value of RegExp.prototype is the RegExp prototype object (21.2.5).

This property shall have the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

21.2.4.2 RegExp[ @@create ]()

The @@create method of an object F performs the following:

1. Return the result of calling the abstract operation RegExpAlloc with argument F.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

21.2.5 Properties of the RegExp Prototype Object

The RegExp prototype object is an ordinary object. It is not a RegExp instance and does not have a [[RegExpMatcher]] internal data property or any of the other internal data properties of RegExp instance objects.

The value of the [[Prototype]] internal data property of the RegExp prototype object is the standard built-in Object prototype object (19.1.4).

The RegExp prototype object does not have a valueOf property of its own; however, it inherits the valueOf property from the Object prototype object.

21.2.5.1 RegExp.prototype.constructor

The initial value of RegExp.prototype.constructor is the standard built-in RegExp constructor.

21.2.5.2 RegExp.prototype.exec(string)

Performs a regular expression match of string against the regular expression and returns an Array object containing the results of the match, or null if string did not match.

The String ToString(string) is searched for an occurrence of the regular expression pattern as follows:

1. Let R be the this value.
2. If Type(R) is not Object, then throw a TypeError exception.
3. If R does not have a [[RegExpMatcher]] internal data property, then throw a TypeError exception.
4. If the value of R’s [[RegExpMatcher]] internal data property is undefined, then throw a TypeError exception.
5. Let S be the value of ToString(string)
6. ReturnIfAbrupt(S).
7. Return the result of the RegExpExec abstract operation with arguments R and S.

Runtime Semantics: RegExpExec Abstract Operation

The abstract operation RegExpExec with arguments R (an object) and S (a string) performs the following steps:

1. Assert: R is an initialised RegExp instance.
2. Let length be the length of S.
3. Let lastIndex be the result of Get(R, "lastIndex").
4. Let i be the value of ToInteger(lastIndex).
5. ReturnIfAbrupt(i).
6. Let global be the result of ToBoolean(Get(R, "global")).
7. ReturnIfAbrupt(global).
8. If global is false, then let i = 0.
9. Let matcher be the value of R’s [[RegExpMatcher]] internal data property.
10. Let matchSucceeded be false.
11. Repeat, while matchSucceeded is false
    a. If i < 0 or i > length, then
       i. Let putStatus be the result of Put(R, "lastIndex", 0, true).
       ii. ReturnIfAbrupt(putStatus).
       iii. Return null.
    b. Let r be the result of calling matcher with arguments S and i.
    c. If r is failure, then
       i. Let i = i + 1.
       d. else
          i. Assert: r is a State.
          ii. Set matchSucceeded to true.
12. Let e be r’s endIndex value.
13. If global is true, then
    a. Let putStatus be the result of Put(R, "lastIndex", e, true).
    b. ReturnIfAbrupt(putStatus).
14. Let n be the length of r’s captures List. (This is the same value as 21.2.2.1’s NCapturingParen.)
15. Let A be the result of the abstract operation ArrayCreate with argument 0.
16. Let matchIndex be i.
17. Assert: The following [[DefineOwnProperty]] calls will not result in an abrupt completion.
18. Call the [[DefineOwnProperty]] internal method of A with arguments “index” and Property Descriptor
    (((Value): matchIndex, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true).
19. Call the [[DefineOwnProperty]] internal method of A with arguments “input” and Property Descriptor
    (((Value): S, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true).
20. Call the [[DefineOwnProperty]] internal method of A with arguments “length” and Property Descriptor
    (((Value): n + 1).
21. Let matchedSubstr be the matched substring (i.e. the portion of S between offset i inclusive and offset e
    exclusive).
22. Call the [[DefineOwnProperty]] internal method of A with arguments “0” and Property Descriptor
    (((Value): matchedSubstr, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true.
23. For each integer i such that 0 > 0 and i ≤ n
    a. Let capture be the 0-th element of i’s captures List.
    b. Call the [[DefineOwnProperty]] internal method of A with arguments ToString(i) and Property
       Descriptor (((Value): capture, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true.
24. Return A.

### 21.2.5.3 get RegExp.prototype.global

RegExp.prototype.global is an accessor property whose set accessor function is undefined. Its get
accessor function performs the following steps:

1. Let R be the this value.
2. If Type(R) is not Object, then throw a TypeError exception.
3. If R does not have a [[OriginalFlags]] internal data property throw a TypeError exception.
4. Let flags be the value of R’s [[OriginalFlags]] internal data property.
5. If flags is undefined, then throw a TypeError exception.
6. If flags contains the character "g", then return true.
7. Return false.
21.2.5.4 \texttt{get RegExp.prototype.ignoreCase}

\texttt{RegExp.prototype.ignoreCase} is an accessor property whose set accessor function is \texttt{undefined}. Its get accessor function performs the following steps:

1. Let \( R \) be the this value.
2. If Type(\( R \)) is not Object, then throw a \texttt{TypeError} exception.
3. If \( R \) does not have a \([\text{OriginalFlags}]\) internal data property throw a \texttt{TypeError} exception.
4. Let flags be the value of \( R \)'s \([\text{OriginalFlags}]\) internal data property.
5. If flags is \texttt{undefined}, then throw a \texttt{TypeError} exception.
6. If flags contains the character "i", then return \texttt{true}.
7. Return \texttt{false}.

21.2.5.5 \texttt{RegExp.prototype.match (string)}

When the \texttt{match} method is called with argument \texttt{string}, the following steps are taken:

1. Let \( rx \) be the this value.
2. If Type(\( rx \)) is not Object, then throw a \texttt{TypeError} exception.
3. If \( rx \) does not have a \([\text{RegExpMatcher}]\) internal data property, then throw a \texttt{TypeError} exception.
4. If the value of \( rx \)'s \([\text{RegExpMatcher}]\) internal data property is \texttt{undefined}, then throw a \texttt{TypeError} exception.
5. Let S be the value of \texttt{ToString(string)}.
6. ReturnIfAbrupt(S).
7. Let global be the result of \texttt{ToBoolean(Get(rx, "global"))}.
8. ReturnIfAbrupt(global).
9. If global is not \texttt{true}, then
   a. Return the result of calling the abstract operation \texttt{RegExpExec} (see 21.2.5.2) with arguments \( rx \) and S.
10. Else global is \texttt{true},
    a. Let putStatus be the result of \texttt{Put(rx, "lastIndex", 0, true)}.
    b. ReturnIfAbrupt(putStatus).
    c. Let A be the result of the abstract operation ArrayCreate with argument 0.
    d. Let previousLastIndex be 0.
    e. Let n be 0.
    f. Let lastMatch be \texttt{true}.
    g. Repeat, while lastMatch is \texttt{true}
       i. Let result be the result of the abstract operation \texttt{RegExpExec} with arguments \( rx \) and S.
       ii. ReturnIfAbrupt(result).
       iii. If result is \texttt{null}, then set \texttt{lastMatch} to \texttt{false}.
       iv. Else result is not \texttt{null},
           1. Let thisIndex be the result of \texttt{ToInteger(Get(rx, "lastIndex"))}.
           2. ReturnIfAbrupt(thisIndex).
           3. If thisIndex = previousLastIndex then
              a. Let putStatus be the result of \texttt{Put(rx, "lastIndex", thisIndex+1, true)}.
              b. ReturnIfAbrupt(putStatus).
              c. Set previousLastIndex to thisIndex+1.
           4. Else,
              a. Set previousLastIndex to thisIndex.
           5. Let matchStr be the result of \texttt{Get(result, "0")}.
           6. Let defineStatus be the result of \texttt{DefinePropertyOrThrow(A, ToString(n), Property Descriptor \([\text{Value}]:\texttt{matchStr}, \texttt{[Writable]}: \texttt{true}, \texttt{[Enumerable]}: \texttt{true}, \texttt{[Configurable]}: \texttt{true})}.
           7. ReturnIfAbrupt(defineStatus).
           8. Increment n.
    b. If \( n = 0 \), then return \texttt{null}.
    i. Return A.
21.2.5.6 get RegExp.prototype.multiline

RegExp.prototype.multiline is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let R be the this value.
2. If Type(R) is not Object, then throw a TypeError exception.
3. If R does not have a [[OriginalFlags]] internal data property, then throw a TypeError exception.
4. Let flags be the value of R's [[OriginalFlags]] internal data property.
5. If flags is undefined, then throw a TypeError exception.
6. If flags contains the character "m", then return true.
7. Return false.

21.2.5.7 RegExp.prototype.replace (S, replaceValue)

When the replace method is called with arguments S and replaceValue the following steps are taken:

TODO: need to finish this and have it make use of GetReplaceSubstitution operation in 21.1.3.14

1. Let rx be the this value.
2. If Type(rx) is not Object, then throw a TypeError exception.
3. If rx does not have a [[RegExpMatcher]] internal data property, then throw a TypeError exception.
4. If the value of rx's [[RegExpMatcher]] internal data property is undefined, then throw a TypeError exception.
5. Let string be ToString(S).
6. ReturnIfAbrupt(string).
7. If searchValue.global is false, then search string for the first match of the regular expression searchValue. If searchValue.global is true, then search string for all matches of the regular expression searchValue. Do the search in the same manner as in RegExp.prototype.match, including the update of searchValue.lastIndex. Let m be the number of left capturing parentheses in searchValue (using NcapturingParens as specified in 21.2.2.1).
8. If replaceValue is a function, then
   a. For each matched substring, call the function with the following m + 3 arguments. Argument 1 is the substring that matched. If searchValue is a regular expression, the next m arguments are all of the captures in the MatchResult (see 21.2.2.1). Argument m + 2 is the offset within string where the match occurred, and argument m + 3 is string. The result is a String value derived from the original input by replacing each matched substring with the corresponding return value of the function call, converted to a String if need be.
9. Else,
   a. Let newstring denote the result of converting replaceValue to a String. The result is a String value derived from the original input String by replacing each matched substring with a String derived from newstring by replacing elements in newstring by replacement text as specified in . These $ replacements are done left-to-right, and, once such a replacement is performed, the new replacement text is not subject to further replacements. For example, "$1,$2".replace(/\$(\d)\$/g, "$\1,$\2") returns "$1,$1,$2". A $ in newstring that does not match any of the forms below is left as is.

21.2.5.8 RegExp.prototype.search (S)

When the search method is called with argument S, the following steps are taken:

1. Let rx be the this value.
2. If Type(rx) is not Object, then throw a TypeError exception.
3. If `rx` does not have a `[[RegExpMatcher]]` internal data property, then throw a `TypeError` exception.
4. If the value of `rx`'s `[[RegExpMatcher]]` internal data property is `undefined`, then throw a `TypeError` exception.
5. Let `string` be `ToString(S).
6. Return `Abrupt(string).
7. Search the value `string` from its beginning for an occurrence of the regular expression pattern `rx`. Let `result` be a Number indicating the offset within `string` where the pattern matched, or -1 if there was no match. If an abrupt completion occurs during the search, `result` is that Completion Record. The `lastIndex` and `global` properties of `regexp` are ignored when performing the search. The `lastIndex` property of `regexp` is left unchanged.
8. Return `result`.

21.2.5.9 `get RegExp.prototype.source`

`RegExp.prototype.source` is an accessor property whose set accessor function is `undefined`. Its get accessor function performs the following steps:

1. Let `R` be the `this` value.
2. If `Type(R)` is not `Object`, then throw a `TypeError` exception.
3. If `R` does not have a `[[OriginalSource]]` internal data property throw a `TypeError` exception.
4. If `R` does not have a `[[OriginalFlags]]` internal data property throw a `TypeError` exception.
5. Let `src` be the value of `R`'s `[[OriginalSource]]` internal data property.
6. Let `flags` be the value of `R`'s `[[OriginalFlags]]` internal data property.
7. If either `src` or `flags` is `undefined`, then throw a `TypeError` exception.
8. Return the result of the abstract operation `EscapeRegExpPattern` with arguments `src` and `flags`.

21.2.5.10 `RegExp.prototype.split (string, limit)`

`Returns an Array object into which substrings of the result of converting `array` to a String have been stored. The substrings are determined by searching from left to right for matches of the this value regular expression; these occurrences are not part of any substring in the returned array, but serve to divide up the String value.

The `this` value may be an empty regular expression or a regular expression that can match an empty String. In this case, regular expression does not match the empty substring at the beginning or end of the input String, nor does it match the empty substring at the end of the previous separator match. (For example, if the regular expression matches the empty String, the String is split into individual code unit elements; the length of the result array equals the length of the String, and each substring contains one code unit.) Only the first match at a given position of the `this` String is considered, even if backtracking could yield a non-empty-substring match at that position. For example, `/a*/.split(“ab”)` evaluates to the array `[“a”, “b”]`, while `/a*/.split(“ab”)` evaluates to the array `[“”, “b”]`.

If the `string` is (or converts to) the empty String, the result depends on whether the regular expression can match the empty String. If it can, the result array contains no elements. Otherwise, the result array contains one element, which is the empty String.

If the regular expression that contains capturing parentheses, then each time `separator` is matched the results (including any `undefined` results) of the capturing parentheses are spliced into the output array. For example, `/<(\()/\([^<]+)(\>)\//.split(“ACBbold</B>and</CODE>coded</CODE>”) evaluates to the array `[“A”, undefined, “B”, “bold”, “/”, “B”, “and”, undefined, “CODE”, “coded”, “/”, “CODE”, “”]`

If limit is not `undefined`, then the output array is truncated so that it contains no more than limit elements.

When the `split` method is called, the following steps are taken:

1. Let `rx` be the `this` value.
2. If Type(`rx`) is not `Object`, then throw a `TypeError` exception.
3. If `rx` does not have a `[[RegExpMatcher]]` internal data property, then throw a `TypeError` exception.

© Ecma International 2013
4. If the value of \( r_1 \)’s [[RegExpMatcher]] internal data property is `undefined`, then throw a `TypeError` exception.
5. Let `matcher` be the value of \( r_1 \)’s [[RegExpMatcher]] internal data property.
6. Let `S` be `ToString(string)`.
7. `ReturnIfAbrupt(S)`.
8. Let `A` be the result of the abstract operation `ArrayCreate` with argument 0.
9. `ReturnIfAbrupt(A)`.
10. If `lengthA` is 0, then let `lengthA = 2\^S - 1`; else let `lengthA = ToLength(limit)`.
11. Let `s` be the number of elements in `S`.
12. Let `p` be 0.
13. If `lim` is `undefined`, let `lim = 2\^S - 1`; else let `lim = ToLength(limit)`.
14. If `lim = 0`, return `A`.
15. If `s = 0`, then
   a. Let `z` be the result of calling the `matcher` with arguments `S` and 0.
   b. `ReturnIfAbrupt(z)`.
   c. If `z` is not `failure`, return `A`.
   d. Let `status` be the result of calling the `[[DefineOwnProperty]]` internal method of `A` with arguments "0" and Property Descriptor `[[Value]]: S, [[Writable]]: true, [[Enumerable]]: true,` `true,` `true,` `true,`  
   e. Assert: `status` is not an abrupt completion.
   f. Return `A`.
16. Let `q = p`.
17. Repeat, while `q ≠ s`:
   a. Let `z` be the result of calling the `matcher` with arguments `S` and `q`.
   b. `ReturnIfAbrupt(z)`.
   c. If `z` is `failure`, then let `q = q + 1`.
   d. Else `z` is not `failure`:
      i. If `q` is `endIndex` and let `cap` be `z:\'s captures List`.
      ii. If `e = p`, then let `q = q + 1`.
      iii. Else `e ≠ p`:
         1. Let `T` be a `String value equal to the substring of `S` consisting of the elements at positions `p` (inclusive) through `q` (exclusive).
         2. Let `status` be the result of calling the `[[DefineOwnProperty]]` internal method of `A` with arguments `ToString(lengthA)` and Property Descriptor `[[Value]]: T,` `true,` `true,` `true,`  
         3. Assert: `status` is not an abrupt completion.
         4. Increment `lengthA` by 1.
         5. If `lengthA = lim`, return `A`.
         7. Let `i = 0`.
         8. Repeat, while `i` is not equal to the number of elements in `cap`:
            a. Let `i = i + 1`.
            b. Let `status` be the result of calling the `[[DefineOwnProperty]]` internal method of `A` with arguments `ToString(lengthA)` and Property Descriptor `[[Value]]: cap[i],` `true,` `true,` `true,`  
            c. Assert: `status` is not an abrupt completion.
            d. Increment `lengthA` by 1.
            e. If `lengthA = lim`, return `A`.
18. Let `T` be a `String value equal to the substring of `S` consisting of the elements at positions `p` (inclusive) through `s` (exclusive).
19. Let `status` be the result of calling the `[[DefineOwnProperty]]` internal method of `A` with arguments `ToString(lengthA)` and Property Descriptor `[[Value]]: T,` `true,` `true,` `true,`  
20. Assert: `status` is not an abrupt completion.

The `length` property of the `split` method is 2.
NOTE 1 The split method ignores the value of the global property of this RegExp object.

21.2.5.11 get RegExp.prototype.sticky

RegExp.prototype.sticky is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let R be the this value.
2. If Type(R) is not Object, then throw a TypeError exception.
3. If R does not have a [[OriginalFlags]] internal data property throw a TypeError exception.
4. Let flags be the value of R’s [[OriginalFlags]] internal data property.
5. If flags is undefined, then throw a TypeError exception.
6. If flags contains the character “y”, then return true.
7. Return false.

21.2.5.12 RegExp.prototype.test(string)

The following steps are taken:

1. Let R be the this value.
2. If Type(R) is not Object, then throw a TypeError exception.
3. If R does not have a [[RegExpMatcher]] internal data property, then throw a TypeError exception.
4. If the value of R’s [[RegExpMatcher]] internal data property is undefined, then throw a TypeError exception.
5. Let S be the value of ToString(string).
6. ReturnIfAbrupt(S).
7. Let match be the result of the RegExpExec abstract operation with arguments R and S.
8. ReturnIfAbrupt(match).
9. If match is not null, then return true; else return false.

21.2.5.13 RegExp.prototype.toString()

1. Let R be the this value.
2. If Type(R) is not Object, then throw a TypeError exception.
3. If R does not have a [[RegExpMatcher]] internal data property, then throw a TypeError exception.
4. If the value of R’s [[RegExpMatcher]] internal data property is undefined, then throw a TypeError exception.
5. Let pattern be the result of ToString(Get(R, “source”)).
6. ReturnIfAbrupt(pattern).
7. Let result be the String value formed by concatenating “/”, pattern, and “/”.
8. Let global be the result of ToBoolean(Get(R, “global”)).
9. ReturnIfAbrupt(global).
10. If global is true, then append “g” as the last character of result.
11. Let ignoreCase be the result of ToBoolean(Get(R, “ignoreCase”)).
12. ReturnIfAbrupt(ignoreCase).
13. If ignoreCase is true, then append “i” as the last character of result.
14. Let multiline be the result of ToBoolean(Get(R, “multiline”)).
15. ReturnIfAbort(multiline).
16. If multiline is true, then append “m” as the last character of result.
17. Let unicode be the result of ToBoolean(Get(R, “unicode”)).
18. ReturnIfAbort(unicode).
19. If unicode is true, then append “u” as the last character of result.
20. Let sticky be the result of ToBoolean(Get(R, “sticky”)).
21. ReturnIfAbort(sticky).
22. If sticky is true, then append “y” as the last character of result.
23. Return result.

NOTE The returned String has the form of a RegularExpressionLiteral that evaluates to another RegExp object with the same behaviour as this object.
21.2.5.14 get RegExp.prototype.unicode

RegExp.prototype.unicode is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let R be the this value.
2. If Type(R) is not Object, then throw a TypeError exception.
3. If R does not have a [[OriginalFlags]] internal data property throw a TypeError exception.
4. Let flags be the value of R's [[OriginalFlags]] internal data property.
5. If flags is undefined, then throw a TypeError exception.
6. If flags contains the character "u", then return true.
7. Return false.

21.2.5.15 RegExp.prototype[@@isRegExp]

The initial value of the @@isRegExp property is true.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

21.2.6 Properties of RegExp Instances

RegExp instances are ordinary objects that inherit properties from the RegExp prototype object. RegExp instances have internal data properties [[RegExpMatcher]], [[OriginalSource]], and [[OriginalFlags]]. The value of the [[RegExpMatcher]] internal data property is an implementation-dependent representation of the Pattern of the RegExp object.

NOTE: Prior to the 6th Edition, RegExp instances were specified as having the own data properties source, global, ignoreCase, and multiline. Those properties are now specified as accessor properties of RegExp.prototype.

RegExp instances also have the following properties:

21.2.6.1 lastIndex

The value of the lastIndex property specifies the String position at which to start the next match. It is coerced to an integer when used (see 21.2.5.2). This property shall have the attributes { [[Writable]]: true, [[Enumerable]]: false, [[Configurable]]: false }.

NOTE: Unlike the other standard built-in properties of RegExp instances, lastIndex is writable.

22 Indexed Collections

22.1 Array Objects

Array objects are exotic objects that give special treatment to a certain class of property names. See 9.2.2 for a definition of this special treatment.

An Array object, O, is said to be sparse if the following algorithm returns true:

1. Let len be the result of Get(O, "length").
2. For each integer i in the range 0 ≤ i < ToUint32(len)
   a. Let elem be the result of calling the [[GetOwnProperty]] internal method of O with argument ToString(i).
   b. If elem is undefined, return true.
3. Return false.

Commented [AWB11141]: TODO: see if this algorithm is really needed
22.1.1 The Array Constructor

The Array constructor is the %Array% intrinsic object and the initial value of the Array property of the global object. When `Array` is called as a function rather than as a constructor, it creates and initialises a new Array object. Thus the function call `Array(...)` is equivalent to the object creation expression `new Array(...)` with the same arguments. However, if the `this` value value passed in the call is an Object with an `[[ArrayInitialisationState]]` internal data property whose value is `undefined`, it initialises the `this` value using the argument values. This permits `Array` to be used both as factory method and to perform constructor instance initialization.

The `Array` constructor is designed to be subclassable. It may be used as the value of an `extends` clause of a class declaration. Subclass constructors that intended to inherit the specified `Array` behaviour must include a `super` call to the `Array` constructor to initialise subclass instances.

22.1.1.1 `Array([item1, item2, ...])`

This description applies if and only if the `Array` constructor is called with no arguments or at least two arguments.

When the `Array` function is called the following steps are taken:

1. Let `numberOfArgs` be the number of arguments passed to this constructor call.
3. Let `O` be the `this` value.
4. If `Type(O)` is Object and `O` has a `[[ArrayInitialisationState]]` internal data property and the value of `[[ArrayInitialisationState]]` is `false`, then
   a. Set the value of `O`'s `[[ArrayInitialisationState]]` internal data property to `true`.
   b. Let `array` be `O`.
5. Else,
   a. Let `F` be this function.
   b. Let `proto` be the result of GetPrototypeFromConstructor(`F`, `%ArrayPrototype%`).
   c. ReturnIfAbrupt(`proto`).
   d. Let `array` be the result of the abstract operation `ArrayCreate` with arguments `numberOfArgs` and `proto`.
6. ReturnIfAbrupt(`array`).
7. Let `k` be `0`.
8. Let `items` be a zero-originated List containing the argument `items` in order.
9. Repeat, while `k < numberOfArgs`.
   a. Let `Pk` be `k` element of `items`.
   b. Let `itemK` be the result of `ToString(Pk)`.
   c. Let `defineStatus` be the result of `DefinePropertyOrThrow(array, Pk, Property Descriptor {[[Value]]: itemK, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true})`.
   d. ReturnIfAbrupt(`defineStatus`).
   e. Increase `k` by `1`.
10. Let `putStatus` be the result of `Put(array, "length", numberOfArgs, true)`.
11. ReturnIfAbrupt(`putStatus`).
12. Return `array`.

22.1.1.2 `Array(len)`

This description applies if and only if the `Array` constructor is called with exactly one argument.

1. Let `numberOfArgs` be the number of arguments passed to this constructor call.
3. Let `O` be the `this` value.
4. If `Type(O)` is Object and `O` has an `[[ArrayInitialisationState]]` internal data property and the value of `[[ArrayInitialisationState]]` is `false`, then
   a. Set the value of `O`'s `[[ArrayInitialisationState]]` internal data property to `true`.
   b. Let `array` be `O`.
5. Else,
   a. Let F be this function.
   b. Let proto be the result of GetPrototypeFromConstructor(F, "ArrayPrototype").
   c. ReturnIfAbrupt(proto).
   d. Let array be the result of ArrayCreate(0, proto).
6. ReturnIfAbrupt(array).
7. If Type(len) is not Number, then
   a. Let defineStatus be the result of DefinePropertyOrThrow(array, "0", Property Descriptor
      {[[Value]]: len, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}).
   b. ReturnIfAbrupt(defineStatus).
   c. Let intLen be 1.
8. Else,
   a. Let intLen be ToUint32(len).
   b. If intLen ≠ len, then throw a RangeError exception.
9. Let putStatus be the result of Put(array, "length", intLen, true).
10. ReturnIfAbrupt(putStatus).
11. Return array.

22.1.1.3 new Array ( ... argumentsList)

When Array is called as part of a new expression, it initialises a newly created object.

1. Let F be the Array function object on which the new operator was applied.
2. Let argumentsList be the argumentsList argument of the [[Construct]] internal method that was invoked by the new operator.
3. Return the result of OrdinaryConstruct(F, argumentsList).

If Array is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.

22.1.2 Properties of the Array Constructor

The value of the [[Prototype]] internal data property of the Array constructor is the Function prototype object (19.2.3).

Besides the length property (whose value is 1), the Array constructor has the following properties:

22.1.2.1 Array.from (arrayLike, mapfn=undefined, thisArg=undefined)

When the from method is called with argument arrayLike and optional arguments mapfn and thisArg the following steps are taken:

1. Let C be the this value.
2. Let items be ToObject(arrayLike).
3. ReturnIfAbrupt(items).
4. If mapfn is undefined, then let mapping be false.
5. else
   a. If IsCallable(mapfn) is false, throw a TypeError exception.
   b. If thisArg was supplied, let T be thisArg; else let T be undefined.
   c. Let mapping be true.
6. Let usingIterator be the result of HasProperty(items, @@Iterator).
7. ReturnIfAbrupt(usingIterator).
8. If usingIterator is true, then
   a. Let iterator be the result of performing GetIterator(items).
   b. ReturnIfAbrupt(iterator).
   c. If IsConstructor(C) is true, then
      i. Let newObj be the result of calling the [[Construct]] internal method of C with an empty argument list.
   d. Else,

Commented [AWB7142]: It would be nice to have a more explicit way to create a collection with a pre-specified number of elements.
i. Let $A$ be the result of the abstract operation ArrayCreate with argument 0.

ii. ReturnIfAbrupt($A$).

iii. Let $k$ be 0.

g. Repeat

i. Let $P_k$ be ToString($k$).

ii. Let $next$ be the result of IteratorNext($iterator$).

iii. ReturnIfAbrupt($next$).

iv. Let done be IteratorComplete($next$).

v. ReturnIfAbrupt($done$).

vi. If $done$ is true, then

1. Let $putStatus$ be the result of Put($A$, "length", $k$, true).

2. ReturnIfAbrupt($putStatus$).

3. Return $A$.

vii. Let $nextValue$ be IteratorValue($next$).

viii. ReturnIfAbrupt($nextValue$).

ix. If $mapping$ is true, then

1. Let $mappedValue$ be the result of calling the [[Call]] internal method of $mapfn$ with $T$ as thisArgument and a List containing $nextValue$ as argumentsList.

2. ReturnIfAbrupt($mappedValue$).

x. Else, let $mappedValue$ be $nextValue$.

xi. Let defineStatus be the result of DefinePropertyOrThrow($A$, $Pk$, Property Descriptor

xii. ReturnIfAbrupt(defineStatus).

xiii. Increase $k$ by 1.

9. Assert: $items$ is not an Iterator so assume it is Array-like.

10. Let $lenValue$ be the result of Get($items$, "length").

11. Let $len$ be ToInteger($lenValue$).

12. ReturnIfAbrupt($len$). If IsConstructor($C$) is true, then

a. Let $newObj$ be the result of calling the [[Construct]] internal method of $C$ with an argument list containing the single item $len$.

b. Let $A$ be ToObject($newObj$).

13. Else,

a. Let $A$ be the result of the abstract operation ArrayCreate with argument $len$.

14. ReturnIfAbrupt($A$).

15. Let $k$ be 0.

16. Repeat, while $k < len$

i. Let $P_k$ be ToString($k$).

ii. Let $kPresent$ be the result of HasProperty($items$, $P_k$).

iii. ReturnIfAbrupt($kPresent$).

iv. If $kPresent$ is true, then

i. Let $kValue$ be the result of Get($items$, $P_k$).

ii. ReturnIfAbrupt($kValue$).

iii. If $mapping$ is true, then

1. Let $mappedValue$ be the result of calling the [[Call]] internal method of $mapfn$ with $T$ as thisArgument and a List containing $kValue$, $k$, and $items$ as argumentsList.

2. ReturnIfAbrupt($mappedValue$).

iv. Else, let $mappedValue$ be $kValue$.

v. Let defineStatus be the result of DefinePropertyOrThrow($A$, $Pk$, Property Descriptor

vi. ReturnIfAbrupt(defineStatus).

vii. Increase $k$ by 1.

17. Let $putStatus$ be the result of Put($A$, "length", $len$, true).

18. ReturnIfAbrupt($putStatus$).

NOTE The function is an intentionally generic factory method; it does not require that its this value be the Array constructor. Therefore it can be transferred to or inherited by any other constructors that may be called with a single numeric argument.
22.1.2.2 Array.isArray (arg)

The `Array.isArray(arg)` function takes one argument `arg`, and performs the following:

1. If `Type(arg)` is not `Object`, return `false`.
2. If `arg` is an exotic Array object, then return `true`.
3. Return `false`.

22.1.2.3 Array.of (...items)

When the `of` method is called with any number of arguments, the following steps are taken:

1. Let `lenValue` be the result of `Get(items, "length")`.
2. Let `len` be `ToInteger(lenValue)`.
3. Let `C` be the `this` value.
4. If `IsConstructor(C)` is `true`, then
   a. Let `newObj` be the result of calling the `[[Construct]]` internal method of `C` with an argument list containing the single item `len`.
5. Else,
   a. Let `A` be the result of the abstract operation `ArrayCreate` with argument `len`.
6. Return `IfAbrupt(A)`.
7. Let `k` be 0.
8. Repeat, while `k < len`:
   a. Let `Pk` be `ToString(k)`.
   b. Let `kValue` be the result of `Get(items, Pk)`.
   c. Let `defineStatus` be the result of `DefinePropertyOrThrow(A, Pk, Property Descriptor {[[Value]]: `kValue`, [[Writable]]: `true`, [[Enumerable]]: `true`, [[Configurable]]: `true`})`.
   d. Return `IfAbrupt(defineStatus)`.
   e. Increase `k` by 1.
9. Let `putStatus` be the result of `Put(A, "length", len, true)`.
10. Return `IfAbrupt(putStatus)`.
11. Return `A`.

The `length` property of the `of` method is 0.

**NOTE 1** The `items` argument is assumed to be a well-formed rest argument value.

**NOTE 2** The `of` function is an intentionally generic factory method; it does not require that its `this` value be the Array constructor. Therefore it can be transferred to or inherited by other constructors that may be called with a single numeric argument.

22.1.2.4 Array.prototype

The value of `Array.prototype` is `%ArrayPrototype%`, the intrinsic Array prototype object (22.1.3).

This property has the attributes {[[Writable]]: `false`, [[Enumerable]]: `false`, [[Configurable]]: `false`}.

22.1.2.5 Array[@@create]()

The `@@create` method of an object `F` performs the following steps:

1. Let `F` be the `this` value.
2. Let `proto` be the result of `GetPrototypeFromConstructor(F, "%ArrayPrototype%")`.
3. Return `IfAbrupt(proto)`.
4. Let `obj` be the result of calling `ArrayCreate` with arguments `undefined` and `proto`.
5. Return `obj`.

This property has the attributes {[[Writable]]: `false`, [[Enumerable]]: `false`, [[Configurable]]: `true`}.
NOTE 1  Passing **undefined** as the first argument to **ArrayCreate** causes the [[ArrayInitialisationState]] internal data property of the array to be initially assigned the value **false**. This is a flag used to indicate that the instance has not yet been initialised by the **Array** constructor. This flag value is never directly exposed to ECMAScript code; hence implementation may choose to encode the flag in any unobservable manner.

NOTE 2  The **Array @@create** function is intentionally generic; it does not require that its **this** value be the **Array** constructor object. It can be transferred to other constructor functions for use as a **@@create** method. When used with other constructors, this function will create an exotic **Array** object whose [[Prototype]] value is obtained from the associated constructor.

### 22.1.3 Properties of the **Array** Prototype Object

The value of the [[Prototype]] internal data property of the **Array** prototype object is the intrinsic object `%ObjectPrototype%`.

The **Array** prototype object is itself an ordinary object. It is not an **Array** instance and does not have a **length** property.

NOTE  The **Array** prototype object does not have a **valueOf** property of its own; however, it inherits the **valueOf** property from the standard built-in **Object** prototype object.

### 22.1.3.1 **Array.prototype.concat ([item1 [ , item2 [ , ... ]]]))**

When the **concat** method is called with zero or more arguments **item1**, **item2**, etc., it returns an array containing the array elements of the object followed by the array elements of each argument in order.

The following steps are taken:

1. Let **O** be the result of calling **ToObject** passing the **this** value as the argument.
2. ReturnIfAbrupt(**O**).
3. Let **A** be **undefined**.
4. If **O** is an exotic **Array** object, then
   a. Let **C** be Get(**O**, "**constructor**").
   b. ReturnIfAbrupt(**C**).
   c. If IsConstructor(**C**) is **true**, then
      i. Let **A** be the result of **OrdinaryConstruct**(C, (0)).
5. If **A** is **undefined**, then
   a. Let **A** be the result of the abstract operation **ArrayCreate** with argument 0.
6. ReturnIfAbrupt(**A**).
7. Let **n** be 0.
8. Let **items** be an internal List whose first element is **O** and whose subsequent elements are, in left to right order, the arguments that were passed to this function invocation.
9. Repeat, while **items** is not empty
   a. Remove the first element from **items** and let **E** be the value of the element.
   b. Let **spreadable** be the result of IsConcatSpreadable(**E**).
   c. ReturnIfAbrupt(**spreadable**).
   d. If **spreadable** is **true**, then
      i. Let **k** be 0.
      ii. Let **enVal** be the result of Get(**E**, "**length**").
      iii. Let **len** be ToLength(**enVal**).
      iv. ReturnIfAbrupt(**len**).
   v. Repeat, while **k** < **len**
      1. Let **P** be ToString(**k**).
      2. Let **exists** be the result of HasProperty(**E**, **P**).
      3. ReturnIfAbrupt(**exists**).
   4. If **exists** is **true**, then
      a. Let **subElement** be the result of Get(**E**, **P**).
      b. Call the [[DefineOwnProperty]] internal method of **A** with arguments
         ToString(**n**) and Property Descriptor ([[Value]]: **subElement**, [[Writable]]: **true**, [[Enumerable]]: **true**, [[Configurable]]: **true**).
5. Increase \( n \) by 1.
6. Increase \( k \) by 1.
   e. Else \( E \) is added as a single item rather than spread,
      i. Call the \([\text{DefineOwnProperty}]\) internal method of \( A \) with arguments \( \text{ToString}(n) \) and
         Property Descriptor \( \{ [\text{Value}]: E, [\text{Writable}]: \text{true}, [\text{Enumerable}]: \text{true}, [\text{Configurable}]: \text{true} \} \).
   ii. Increase \( n \) by 1.
10. Let \( \text{putStatus} \) be the result of \( \text{Put}(A, \text{“length”}, n, \text{true}) \).
11. \( \text{ReturnIfAbrupt}(\text{putStatus}) \).
12. \( \text{Return} A \).

The \( \text{length} \) property of the \( \text{concat} \) method is 1.

NOTE 1 The explicit setting of the \( \text{length} \) property in step 9 is necessary to ensure that its value is correct in situations where the trailing elements of the result Array are not present.

NOTE 2 The \( \text{concat} \) function is intentionally generic; it does not require that its \( \text{this} \) value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the \( \text{concat} \) function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.1.1 \( \text{IsConcatSpreadable}(O) \) Abstract Operation

The abstract operation \( \text{IsConcatSpreadable} \) with argument \( O \) performs the following steps:

1. \( \text{ReturnIfAbrupt}(O) \).
2. If \( \text{Type}(O) \) is not Object, then throw a \( \text{TypeError} \) exception.
3. Let \( \text{spreadable} \) be \( \text{Get}(O, @\@\text{isConcatSpreadable}) \).
4. \( \text{ReturnIfAbrupt}(\text{spreadable}) \).
5. If \( \text{spreadable} \) is not undefined, then return \( \text{ToBoolean}(<\text{spreadable}>\)).
6. If \( O \) is an exotic Array object, then return \( \text{true} \).
7. Return \( \text{false} \).

22.1.3.2 \( \text{Array.prototype.constructor} \)

The initial value of \( \text{Array.prototype.constructor} \) is the standard built-in \( \text{Array} \) constructor.

22.1.3.3 \( \text{Array.prototype.copyWith}(\text{target}, \text{start}, \text{end} = \text{this}.\text{length}) \)

The \( \text{copyWith} \) method takes up to three arguments \( \text{target}, \text{start} \) and \( \text{end} \). The \( \text{end} \) argument is optional with the length of the \( \text{this} \object as its default value. If \( \text{target} \) is negative, it is treated as \( \text{length}+\text{target} \) where \( \text{length} \) is the length of the array. If \( \text{start} \) is negative, it is treated as \( \text{length}+\text{start} \). If \( \text{end} \) is negative, it is treated as \( \text{length}+\text{end} \). The following steps are taken:

1. Let \( O \) be the result of calling \( \text{ToObject} \) passing the \( \text{this} \) value as the argument.
2. \( \text{ReturnIfAbrupt}(O) \).
3. Let \( \text{lenVal} \) be the result of \( \text{Get}(O, \text{“length”}) \).
4. Let \( \text{len} \) be \( \text{ToLength}(\text{lenVal}) \).
5. \( \text{ReturnIfAbrupt}(\text{len}) \).
6. Let \( \text{len} \) be \( \text{max}(\text{len}, 0) \).
7. Let \( \text{relativeTarget} \) be \( \text{ToInteger}(\text{target}) \).
8. If \( \text{relativeTarget} \) is negative, let \( \text{to} \) be \( \text{max}((\text{len}+\text{relativeStart}),0) \); else let \( \text{to} \) be \( \text{min}(\text{relativeStart}, \text{len}) \).
9. \( \text{ReturnIfAbrupt}(\text{relativeTarget}) \).
10. Let \( \text{relativeStart} \) be \( \text{ToInteger}(\text{start}) \).
11. \( \text{ReturnIfAbrupt}(\text{relativeStart}) \).
12. If \( \text{relativeStart} \) is negative, let \( \text{from} \) be \( \text{max}((\text{len}+\text{relativeStart}),0) \); else let \( \text{from} \) be \( \text{min}(\text{relativeStart}, \text{len}) \).
13. If \( \text{end} \) is undefined, let \( \text{relativeEnd} \) be \( \text{len} \); else let \( \text{relativeEnd} \) be \( \text{ToInteger}(\text{end}) \).
14. \( \text{ReturnIfAbrupt}(\text{relativeEnd}) \).
15. If \( \text{relativeEnd} \) is negative, let \( \text{final} \) be \( \text{max}((\text{len}+\text{relativeEnd}),0) \); else let \( \text{final} \) be \( \text{min}(\text{relativeEnd}, \text{len}) \).
16. Let \( \text{count} \) be \( \text{min}(\text{final-from}, \text{len-to}) \).
17. If from<to and to<from+count
   a. Let direction = -1.
   b. Let from = from + count - 1.
   c. Let to = to + count - 1.
18. Else,
   a. Let direction = 1.
19. Repeat, while count > 0
   a. Let fromKey be ToString(from).
   b. Let toKey be ToString(to).
   c. Let fromPresent be the result of HasProperty(O, fromKey).
   d. ReturnIfAbrupt(fromPresent).
   e. If fromPresent is true, then
      i. Let fromVal be the result of Get(O, fromKey).
      ii. ReturnIfAbrupt(fromVal).
      iii. Let putStatus be the result of Put(O, toKey, fromVal, true).
      iv. ReturnIfAbrupt(putStatus).
   f. Else fromPresent is false,
      i. Let deleteStatus be the result of DeletePropertyOrThrow(O, toKey).
      ii. ReturnIfAbrupt(deleteStatus).
   g. Let from be from + direction.
   h. Let to be to + direction.
   i. Let count be count - 1.
20. Return O.

The length property of the fill method is 2.

NOTE 1 The copyWith function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the copyWith function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.4 Array.prototype.entries ()

The following steps are taken:
1. Let O be the result of calling ToObject with the this value as its argument.
2. ReturnIfAbrupt(O).
3. Return the result of calling the CreateArrayIterator abstract operation with arguments O and "key+value".

22.1.3.5 Array.prototype.every (callbackfn [, thisArg ])

callbackfn should be a function that accepts three arguments and returns a value that is coercible to the Boolean value true or false. every calls callbackfn once for each element present in the array, in ascending order, until it finds one where callbackfn returns false. If such an element is found, every immediately returns false. Otherwise, if callbackfn returned true for all elements, every will return true. callbackfn is called only for elements of the array which actually exist; it is not called for missing elements of the array.

If a thisArg parameter is provided, it will be used as the this value for each invocation of callbackfn. If it is not provided, undefined is used instead.

callbackfn is called with three arguments: the value of the element, the index of the element, and the object being traversed.

every does not directly mutate the object on which it is called but the object may be mutated by the calls to callbackfn.

The range of elements processed by every is set before the first call to callbackfn. Elements which are appended to the array after the call to every begins will not be visited by callbackfn. If existing elements of the array are changed, their value as passed to callbackfn will be the value at the time every visits them;
elements that are deleted after the call to `every` begins and before being visited are not visited. `every` acts like the "for all" quantifier in mathematics. In particular, for an empty array, it returns `true`.

When the `every` method is called with one or two arguments, the following steps are taken:

1. Let `O` be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let `lenValue` be the result of Get(O, "length")
4. Let `len` be ToLength(lenValue).
5. ReturnIfAbrupt(len).
6. If IsCallable(callbackfn) is false, throw a TypeError exception.
7. If thisArg was supplied, let `T` be thisArg; else let `T` be undefined.
8. Let `k` be 0.
9. Repeat, while `k` < `len`
   a. Let `Pk` be ToString(`k`).
   b. Let `kPresent` be the result of HasProperty(O, `Pk`).
   c. ReturnIfAbrupt(`kPresent`).
   d. If `kPresent` is true, then
      i. Let `kValue` be the result of Get(O, `Pk`).
      ii. ReturnIfAbrupt(`kValue`).
      iii. Let `testResult` be the result of calling the [[Call]] internal method of `callbackfn` with `T` as `thisArgument` and a List containing `kValue`, `k`, and `O as argumentsList`.
      iv. ReturnIfAbrupt(`testResult`).
      v. If ToBoolean(`testResult`) is false, return false.
   e. Increase `k` by 1.
10. Return `true`.

The `length` property of the `every` method is 1.

NOTE The `every` function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the `every` function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.6 Array.prototype.fill (value, start = 0, end = this.length)

The fill method takes up to three arguments value, start and end. The start and end arguments are optional with default values of 0 and the length of the this object. If start is negative, it is treated as length-start where length is the length of the array. If end is negative, it is treated as length-end. The following steps are taken:

1. Let `O` be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let `lenVal` be the result of Get(O, "length").
4. Let `len` be ToLength(lenVal).
5. ReturnIfAbrupt(len).
6. Let `lenValue` be max(len, 0).
7. Let relativeStart be ToInteger(start).
8. ReturnIfAbrupt(relativeStart).
9. If relativeStart is greater, let `k` be max((len + relativeStart), 0); else let `k` be min(relativeStart, len).
10. If `end` is undefined, let relativeEnd be len, else let relativeEnd be ToInteger(end).
11. ReturnIfAbrupt(relativeEnd).
12. If relativeEnd is negative, let final be max((len + relativeEnd), 0); else let final be min(relativeEnd, len).
13. Repeat, while `k` < `final`
   a. Let `Pk` be ToString(`k`).
   b. Let `putStatus` be the result of Put(O, `Pk`, value, true).
   c. ReturnIfAbrupt(`putStatus`).
   d. Increase `k` by 1.

The `length` property of the fill method is 1.
NOTE 1 The fill function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the fill function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.7 Array.prototype.fill (callbackfn [, thisArg ])

callbackfn should be a function that accepts three arguments and returns a value that is coercible to the Boolean value true or false. filter calls callbackfn once for each element in the array, in ascending order, and constructs a new array of all the values for which callbackfn returns true. callbackfn is called only for elements of the array which actually exist; it is not called for missing elements of the array.

If a thisArg parameter is provided, it will be used as the this value for each invocation of callbackfn. If it is not provided, undefined is used instead.

callbackfn is called with three arguments: the value of the element, the index of the element, and the object being traversed.

filter does not directly mutate the object on which it is called but the object may be mutated by the calls to callbackfn.

The range of elements processed by filter is set before the first call to callbackfn. Elements which are appended to the array after the call to filter begins will not be visited by callbackfn. If existing elements of the array are changed their value as passed to callbackfn will be the value at the time filter visits them; elements that are deleted after the call to filter begins and before being visited are not visited.

When the filter method is called with one or two arguments, the following steps are taken:

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenValue be the result of Get(O, "length").
4. Let len be ToLength(lenValue).
5. ReturnIfAbrupt(len).
6. If IsCallable(callbackfn) is false, throw a TypeError exception.
7. If thisArg was supplied, let T be thisArg; else let T be undefined.
8. Let A be undefined.
9. If O is an exotic Array object, then
    a. Let C be Get(O, "+constructor").
   b. ReturnIfAbrupt(C).
   c. If IsConstructor(C) is true, then
      i. Let newObj be the result of calling the [[Construct]] internal method of C with an argument list containing the single item 0.
10. If A is undefined, then
    a. Let A be the result of the abstract operation ArrayCreate with argument 0.
11. ReturnIfAbrupt(A).
12. Let k be 0.
13. Let to be 0.
14. Repeat, while k < len
    a. Let Pk be ToString(k).
    b. Let kPresent be the result of HasProperty(O, Pk).
    c. ReturnIfAbrupt(kPresent).
    d. If kPresent is true, then
       i. Let kValue be the result of Get(O, Pk).
       ii. ReturnIfAbrupt(kValue).
       iii. Let selected be the result of calling the [[Call]] internal method of callbackfn with T as thisArgument and a List containing kValue, k, and O as argumentsList.
      iv. ReturnIfAbrupt(selected).
    v. If ToBoolean(selected) is true, then
1. Call the [[DefineOwnProperty]] internal method of A with arguments ToString(to) and Property Descriptor {[[Value]]: kValue, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}.
2. Increase to by 1.
3. Increase k by 1.
4. Return A.

The `length` property of the `filter` method is 1.

**NOTE** The `filter` function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the `filter` function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.8 Array.prototype.find ( predicate , thisArg = undefined )

*predicate* should be a function that accepts three arguments and returns a value that is coercible to the Boolean value true or false. `find` calls `predicate` once for each element present in the array, in ascending order, until it finds one where `predicate` returns true. If such an element is found, `find` immediately returns that element value. Otherwise, `find` returns `undefined`. `predicate` is called only for elements of the array which actually exist; it is not called for missing elements of the array.

If a `thisArg` parameter is provided, it will be used as the `this` value for each invocation of `predicate`. If it is not provided, `undefined` is used instead.

`predicate` is called with three arguments: the value of the element, the index of the element, and the object being traversed.

`find` does not directly mutate the object on which it is called but the object may be mutated by the calls to `predicate`.

The range of elements processed by `find` is set before the first call to `callbackfn`. Elements that are appended to the array after the call to `find` begins will not be visited by `callbackfn`. If existing elements of the array are changed, their value as passed to `predicate` will be the value at the time that `find` visits them; elements that are deleted after the call to `find` begins and before being visited are not visited.

When the `find` method is called with one or two arguments, the following steps are taken:

1. Let `O` be the result of calling ToObject passing the `this` value as the argument.
2. ReturnIfAbrupt(`O`).
3. Let `lenValue` be the result of Get(`O`, "length").
4. Let `len` be ToLength(`lenValue`).
5. ReturnIfAbrupt(`len`).
6. If IsCallable(`predicate`) is false, throw a TypeError exception.
7. If `thisArg` was supplied, let `T` be `thisArg`; else let `T` be `undefined`.
8. Let `k` be 0.
9. Repeat, while `k` < `len`
   1. Let `Pk` be ToString(`k`).
   2. Let `kPresent` be the result of HasProperty(`O`, `Pk`).
   3. ReturnIfAbrupt(`kPresent`).
   4. If `kPresent` is true, then
      i. Let `kValue` be the result of Get(`O`, `Pk`).
      ii. ReturnIfAbrupt(`kValue`).
      iii. Let `testResult` be the result of calling the [[Call]] internal method of `predicate` with `T` as thisArgument and a List containing `kValue`, `k`, and `O` as argumentsList.
      iv. ReturnIfAbrupt(`testResult`).
      v. If ToBoolean(`testResult`) is true, return `kValue`.
     e. Increase `k` by 1.
10. Return `undefined`.

The `length` property of the `find` method is 1.
NOTE The find function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the find function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.9 Array.prototype.findIndex (predicate, thisArg = undefined)

predicate should be a function that accepts three arguments and returns a value that is coercible to the Boolean value true or false. findIndex calls predicate once for each element present in the array, in ascending order, until it finds one where predicate returns true. If such an element is found, findIndex immediately returns the index of that element value. Otherwise, findIndex returns -1. predicate is called only for elements of the array which actually exist; it is not called for missing elements of the array.

If a thisArg parameter is provided, it will be used as the this value for each invocation of predicate. If it is not provided, undefined is used instead.

predicate is called with three arguments: the value of the element, the index of the element, and the object being traversed.

findIndex does not directly mutate the object on which it is called but the object may be mutated by the calls to predicate.

The range of elements processed by findIndex is set before the first call to callbackfn. Elements that are appended to the array after the call to findIndex begins will not be visited by callbackfn. If existing elements of the array are changed, their value as passed to predicate will be the value at the time that findIndex visits them; elements that are deleted after the call to findIndex begins and before being visited are not visited.

When the findIndex method is called with one or two arguments, the following steps are taken:

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenValue be the result of Get(O, "length").
4. Let len be ToLength(lenValue).
5. ReturnIfAbrupt(len).
6. If IsCallable(predicate) is false, throw a TypeError exception.
7. If thisArg was supplied, let T be thisArg; else let T be undefined.
8. Let k be 0.
9. Repeat, while k < len
   a. Let Pk be ToString(k).
   b. Let kPresent be the result of HasProperty(O, Pk).
   c. ReturnIfAbrupt(kPresent).
   d. If kPresent is true, then
      i. Let kValue be the result of Get(O, Pk).
      ii. ReturnIfAbrupt(kValue).
      iii. Let testResult be the result of calling the [[Call]] internal method of predicate with T as thisArgument and a List containing kValue, k, and O as argumentsList.
      iv. ReturnIfAbrupt(testResult).
      v. If ToBoolean(testResult) is true, return k.
   e. Increase k by 1.

The length property of the findIndex method is 1.

NOTE The findIndex function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the findIndex function can be applied successfully to an exotic object that is not an Array is implementation-dependent.
22.1.3.10 Array.prototype.forEach (callbackfn [, thisArg ])

callbackfn should be a function that accepts three arguments. forEach calls callbackfn once for each element present in the array, in ascending order. callbackfn is called only for elements of the array which actually exist; it is not called for missing elements of the array.

If a thisArg parameter is provided, it will be used as the this value for each invocation of callbackfn. If it is not provided, undefined is used instead.

callbackfn is called with three arguments: the value of the element, the index of the element, and the object being traversed.

forEach does not directly mutate the object on which it is called but the object may be mutated by the calls to callbackfn.

The range of elements processed by forEach is set before the first call to callbackfn. Elements which are appended to the array after the call to forEach begins will not be visited by callbackfn. If existing elements of the array are changed, their value as passed to callback will be the value at the time forEach visits them; elements that are deleted after the call to forEach begins and before being visited are not visited.

When the forEach method is called with one or two arguments, the following steps are taken:

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenValue be the result of Get(O, "length").
4. Let len be ToLength(lenValue).
5. ReturnIfAbrupt(len).
6. If IsCallable(callbackfn) is false, throw a TypeError exception.
7. If thisArg was supplied, let T be thisArg; else let T be undefined.
8. Let k be 0.
9. Repeat, while k < len
   a. Let Pk be ToString(k).
   b. Let kPresent be the result of HasProperty(O, Pk).
   c. ReturnIfAbrupt(kPresent).
   d. If kPresent is true, then
      i. Let kValue be the result of Get(O, Pk).
      ii. ReturnIfAbrupt(kValue).
      iii. Let funcResult be the result of calling the [[Call]] internal method of callbackfn with T as thisArgument and a List containing kValue, k, and O as argumentsList.
      iv. ReturnIfAbrupt(funcResult).
   e. Increase k by 1.
10. Return undefined.

The length property of the forEach method is 1.

NOTE The forEach function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the forEach function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.11 Array.prototype.indexOf (searchElement [, fromIndex ])

indexOf compares searchElement to the elements of the array, in ascending order, using the Strict Equality Comparison algorithm (7.2.10), and if found at one or more positions, returns the index of the first such position; otherwise, -1 is returned.

The optional second argument fromIndex defaults to 0 (i.e. the whole array is searched). If it is greater than or equal to the length of the array, -1 is returned, i.e. the array will not be searched. If it is negative, it is used as the offset from the end of the array to compute fromIndex. If the computed index is less than 0, the whole array will be searched.
When the `indexOf` method is called with one or two arguments, the following steps are taken:

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenValue be the result of Get(O, "length")
4. Let len be ToLength(lenValue).
5. ReturnIfAbrupt(len).
6. If len is 0, return -1.
7. If argument fromIndex was passed let n be ToInteger(fromIndex); else let n be 0.
8. ReturnIfAbrupt(n).
9. If n ≥ len, return -1.
10. If n ≥ 0, then
    a. Let k be n.
11. Else n<0,
    a. Let k be len - abs(n).
    b. If k < 0, then let k be 0.
12. Repeat, while k<len
    a. Let kPresent be the result of HasProperty(O, ToString(k)).
    b. ReturnIfAbrupt(kPresent).
    c. If kPresent is true, then
        i. Let elementK be the result of Get(O, ToString(k)).
        ii. ReturnIfAbrupt(elementK).
        iii. Let same be the result of performing Strict Equality Comparison searchElement === elementK.
        iv. If same is true, return k.
    d. Increase k by 1.

The length property of the `indexOf` method is 1.

**NOTE** The `indexOf` function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the `indexOf` function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

### 22.1.3.12 Array.prototype.join (separator)

The elements of the array are converted to Strings, and these Strings are then concatenated, separated by occurrences of the separator. If no separator is provided, a single comma is used as the separator.

The `join` method takes one argument, separator, and performs the following steps:

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenVal be the result of Get(O, "length").
4. Let len be ToLength(lenVal).
5. ReturnIfAbrupt(len).
6. If separator is undefined, let separator be the single-character String ",".
7. Let sep be ToString(separator).
8. If len is zero, return the empty String.
9. Let element0 be the result of Get(O, "0")
10. If element0 is undefined or null, let R be the empty String; otherwise, let R be ToString(element0).
11. ReturnIfAbrupt(R).
12. Let k be 1.
13. Repeat, while k < len
    a. Let S be the String value produced by concatenating R and sep.
    b. Let element be the result of Get(O, ToString(k)).
    c. If element is undefined or null, then let next be the empty String; otherwise, let next be ToString(element).
    d. ReturnIfAbrupt(next).
    e. Let R be a String value produced by concatenating S and next.
f. Increase \( k \) by 1.

14. Return \( R \).

The \texttt{length} property of the \texttt{join} method is 1.

\textbf{NOTE} 

The \texttt{join} function is intentionally generic; it does not require that its \texttt{this} value be an Array object. Therefore, it can be transferred to other kinds of objects for use as a method. Whether the \texttt{join} function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.13 \texttt{Array.prototype.keys ( )}

The following steps are taken:

1. Let \( O \) be the result of calling ToObject with the \texttt{this} value as its argument.
2. ReturnIfAbrupt(\( O \)).
3. Return the result of calling the CreateArrayIterator abstract operation with arguments \( O \) and "\texttt{key}".

22.1.3.14 \texttt{Array.prototype.lastIndexOf ( searchElement [ , fromIndex ] )}

\texttt{lastIndexOf} compares \texttt{searchElement} to the elements of the array in descending order using the Strict Equality Comparison algorithm (7.2.10), and if found at one or more positions, returns the index of the last such position; otherwise, \(-1\) is returned.

The optional second argument \( \text{fromIndex} \) defaults to the array's length minus one (i.e. the whole array is searched). If it is greater than or equal to the length of the array, the whole array will be searched. If it is negative, it is used as the offset from the end of the array to compute \( \text{fromIndex} \). If the computed index is less than 0, \(-1\) is returned.

When the \texttt{lastIndexOf} method is called with one or two arguments, the following steps are taken:

1. Let \( O \) be the result of calling ToObject passing the \texttt{this} value as the argument.
2. ReturnIfAbrupt(\( O \)).
3. Let \( \text{lenValue} \) be the result of Get(\( O \), "\texttt{length}").
4. Let \( \text{len} \) be ToLength(\( \text{lenValue} \)).
5. ReturnIfAbrupt(\( \text{len} \)).
6. If \( \text{len} \) is 0, return \(-1\).
7. If argument \( \text{fromIndex} \) was passed let \( n \) be ToInteger(\( \text{fromIndex} \)); else let \( n \) be \( \text{len} - 1 \).
8. ReturnIfAbrupt(\( n \)).
9. If \( n \geq 0 \), then let \( k \) be \( \min(n, \text{len} - 1) \).
10. Else \( k \neq 0 \),

a. Let \( k \) be \( \text{len} - \text{abs}(n) \).
11. Repeat, while \( k \geq 0 \)

a. Let \( k \) be the result of HasProperty(\( O \), ToString(\( k \))).
   b. ReturnIfAbrupt(\( k \) present).
   c. If \( k \) present is true then
      i. Let \( \text{elementK} \) be the result of Get(\( O \), ToString(\( k \))).
      ii. ReturnIfAbrupt(\( \text{elementK} \)).
      iii. Let \( \text{same} \) be the result of performing Strict Equality Comparison \( \text{searchElement} === \text{elementK} \).
      iv. If \( \text{same} \) is true, return \( k \).
   d. Decrease \( k \) by 1.
12. Return \(-1\).

The \texttt{length} property of the \texttt{lastIndexOf} method is 1.

\textbf{NOTE} 

The \texttt{lastIndexOf} function is intentionally generic; it does not require that its \texttt{this} value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the \texttt{lastIndexOf} function can be applied successfully to an exotic object that is not an Array is implementation-dependent.
22.1.3.15 Array.prototype.map (callbackfn [ , thisArg ])

callbackfn should be a function that accepts three arguments. map calls callbackfn once for each element in the array, in ascending order, and constructs a new Array from the results. callbackfn is called only for elements of
the array which actually exist; it is not called for missing elements of the array.

If a thisArg parameter is provided, it will be used as the this value for each invocation of callbackfn. If it is not
provided, undefined is used instead.

callbackfn is called with three arguments: the value of the element, the index of the element, and the object
being traversed.

map does not directly mutate the object on which it is called but the object may be mutated by the calls to
callbackfn.

The range of elements processed by map is set before the first call to callbackfn. Elements which are
appended to the array after the call to map begins will not be visited by callbackfn. If existing elements of the
array are changed, their value as passed to callbackfn will be the value at the time map visits them; elements
that are deleted after the call to map begins and before being visited are not visited.

When the map method is called with one or two arguments, the following steps are taken:

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenValue be the result of Get(O, "length").
4. Let len be ToLength(lenValue).
5. ReturnIfAbrupt(len).
6. If IsCallable(callbackfn) is false, throw a TypeError exception.
7. If thisArg was supplied, let T be thisArg; else let T be undefined.
8. Let A be undefined.
9. If O is an exotic Array object, then
   a. Let C be Get(O, "constructor").
   b. ReturnIfAbrupt(C).
   c. If IsConstructor(C) is true, then
      i. Let newObj be the result of calling the [[Construct]] internal method of C with an argument
         list containing the single item len.
   10. If A is undefined, then
      a. Let A be the result of the abstract operation ArrayCreate with argument len.
   11. ReturnIfAbrupt(A).
   12. Let k be 0.
   13. Repeat, while k < len
      a. Let Pk be ToString(k).
      b. Let kPresent be the result of HasProperty(O, Pk).
      c. ReturnIfAbrupt(kPresent).
      d. If kPresent is true, then
         i. Let kValue be the result of Get(O, Pk).
         ii. ReturnIfAbrupt(kValue).
         iii. Let mappedValue be the result of calling the [[Call]] internal method of callbackfn with T as
             thisArgument and a List containing kValue, k, and O as argumentsList.
         iv. ReturnIfAbrupt(mappedValue).
         v. Call the [[DefineOwnProperty]] internal method of A with arguments Pk and Property
            Descriptor {[[Value]]; mappedValue, [[Writable]]; true, [[Enumerable]]; true,
            [[Configurable]]; true}.
      e. Increase k by 1.
   14. Return A.

The length property of the map method is 1.
NOTE The `map` function is intentionally generic; it does not require that its `this` value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the `map` function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.16 `Array.prototype.pop()`

The last element of the array is removed from the array and returned.

1. Let `O` be the result of calling `ToObject` passing the `this` value as the argument.
2. ReturnIfAbrupt(`O`).
3. Let `lenVal` be the result of `Get(O, "length")`.
4. Let `len` be `ToLength(lenVal)`.
5. ReturnIfAbrupt(`len`).
6. If `len` is zero,
   a. Let `putStatus` be the result of `Put(O, "length", 0, true)`.
   b. ReturnIfAbrupt(`putStatus`).
   c. Return `undefined`.
7. Else `len > 0`,
   a. Let `newLen` be `len-1`.
   b. Let `index` be `ToString(newLen)`.
   c. Let `element` be the result of `Get(O, index)`.
   d. ReturnIfAbrupt(`element`).
   e. Let `deleteStatus` be the result of `DeletePropertyOrThrow(O, index)`.
   f. ReturnIfAbrupt(`deleteStatus`).
   g. Let `putStatus` be the result of `Put(O, "length", newLen, true)`.
   h. ReturnIfAbrupt(`putStatus`).
   i. Return `element`.

NOTE The `pop` function is intentionally generic; it does not require that its `this` value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the `pop` function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.17 `Array.prototype.push([item1[, item2[, ...]]])`

The arguments are appended to the end of the array, in the order in which they appear. The new length of the array is returned as the result of the call.

When the `push` method is called with zero or more arguments `item1, item2,` etc., the following steps are taken:

1. Let `O` be the result of calling `ToObject` passing the `this` value as the argument.
2. ReturnIfAbrupt(`O`).
3. Let `lenVal` be the result of `Get(O, "length")`.
4. Let `len` be `ToLength(lenVal)`.
5. ReturnIfAbrupt(`len`).
6. Let `items` be an internal List whose elements are, in left to right order, the arguments that were passed to this function invocation.
7. Repeat, while `items` is not empty
   a. Remove the first element from `items` and let `E` be the value of the element.
   b. Let `putStatus` be the result of `Put(O, ToString(n), E, true)`.
   c. ReturnIfAbrupt(`putStatus`).
   d. Increase `n` by 1.
8. Let `putStatus` be the result of `Put(O, "length", n, true)`.
9. ReturnIfAbrupt(`putStatus`).
10. Return `n`.

The `length` property of the `push` method is 1.
NOTE The `push` function is intentionally generic; it does not require that its `this` value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the `push` function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.18 `Array.prototype.reduce (callbackfn [, initialValue])`

`callbackfn` should be a function that takes four arguments. `reduce` calls the callback, as a function, once for each element present in the array, in ascending order.

`callbackfn` is called with four arguments: the `previousValue` (or value from the previous call to `callbackfn`), the `currentValue` (value of the current element), the `currentIndex`, and the object being traversed. The first time that `callback` is called, the `previousValue` and `currentValue` can be one of two values. If an `initialValue` was provided in the call to `reduce`, then `previousValue` will be equal to `initialValue` and `currentValue` will be equal to the first value in the array. If no `initialValue` was provided, then `previousValue` will be equal to the first value in the array and `currentValue` will be equal to the second. It is a `TypeError` if the array contains no elements and `initialValue` is not provided.

`reduce` does not directly mutate the object on which it is called but the object may be mutated by the calls to `callbackfn`.

The range of elements processed by `reduce` is set before the first call to `callbackfn`. Elements that are appended to the array after the call to `reduce` begins will not be visited by `callbackfn`. If existing elements of the array are changed, their value as passed to `callbackfn` will be the value at the time `reduce` visits them; elements that are deleted after the call to `reduce` begins and before being visited are not visited.

When the `reduce` method is called with one or two arguments, the following steps are taken:

1. Let `O` be the result of calling `ToObject` passing the `this` value as the argument.
2. ReturnIfAbrupt(`O`).
3. Let `lenValue` be the result of `Get`(`O`, `"length"`).
4. Let `len` be `ToLength`(`lenValue`).
5. ReturnIfAbrupt(`len`).
6. If `IsCallable`(`callbackfn`) is false, throw a `TypeError` exception.
7. If `len` is 0 and `initialValue` is not present, throw a `TypeError` exception.
8. Let `k` be 0.
9. If `initialValue` is present, then
   a. Set `accumulator` to `initialValue`.
10. Else `initialValue` is not present,
    a. Let `kPresent` be false.
    b. Repeat, while `kPresent` is false and `k < len`
       i. Let `Pk` be `ToString`(k).
       ii. Let `kPresent` be the result of `HasProperty`(`O`, `Pk`).
       iii. ReturnIfAbrupt(`kPresent`).
       iv. If `kPresent` is `true`, then
           1. Let `kValue` be the result of `Get`(`O`, `Pk`).
           2. `ReturnIfAbrupt(accumulator)`.
           3. Increase `k` by 1.
           4. If `kPresent` is false, throw a `TypeError` exception.
    c. If `kPresent` is `false`, throw a `TypeError` exception.
11. Repeat, while `k < len`
    a. Let `Pk` be `ToString`(k).
    b. Let `kPresent` be the result of `HasProperty`(`O`, `Pk`).
    c. `ReturnIfAbrupt(kPresent)`.
    d. If `kPresent` is `true`, then
        i. Let `kValue` be the result of `Get`(`O`, `Pk`).
        ii. `ReturnIfAbrupt(kValue)`.
        iii. Let `accumulator` be the result of calling the `[[Call]]` internal method of `callbackfn` with `undefined` as `this` argument and a List containing `accumulator`, `kValue`, `k`, and `O` as `argumentsList`.
        iv. `ReturnIfAbrupt(accumulator)`. 
e. Increase \( k \) by 1.

12. Return accumulator.

The length property of the reduce method is 1.

NOTE The reduce function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the reduce function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.19 Array.prototype.reduceRight ( callbackfn \[ , initialValue \] )

callbackfn should be a function that takes four arguments. reduceRight calls the callback, as a function, once for each element present in the array, in descending order.

callbackfn is called with four arguments: the previousValue (or value from the previous call to callbackfn), the currentValue (value of the current element), the currentIndex, and the object being traversed. The first time the function is called, the previousValue and currentValue can be one of two values. If an initialValue was provided in the call to reduceRight, then previousValue will be equal to initialValue and currentValue will be equal to the last value in the array. If no initialValue was provided, then previousValue will be equal to the last value in the array and currentValue will be equal to the second-to-last value. It is a TypeError if the array contains no elements and initialValue is not provided.

reduceRight does not directly mutate the object on which it is called but the object may be mutated by the calls to callbackfn.

The range of elements processed by reduceRight is set before the first call to callbackfn. Elements that are appended to the array after the call to reduceRight begins will not be visited by callbackfn. If existing elements of the array are changed by callbackfn, their value as passed to callbackfn will be the value at the time reduceRight visits them; elements that are deleted after the call to reduceRight begins and before being visited are not visited.

When the reduceRight method is called with one or two arguments, the following steps are taken:

1. Let \( O \) be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenValue be the result of Get\( (O, "length") \).
4. Let len be ToLength(lenValue).
5. ReturnIfAbrupt(len).
6. If IsCallable(callbackfn) is false, throw a TypeError exception.
7. If len is 0 and initialValue is not present, throw a TypeError exception.
8. Let \( k \) be len - 1.
9. If initialValue is present, then
   a. Set accumulator to initialValue.
10. Else initialValue is not present, then
    a. Let kPresent be false.
    b. Repeat, while kPresent is false and \( k \geq 0 \)
      i. Let Pk be ToString\( (k) \).
      ii. Let kPresent be the result of HasProperty\( (O, Pk) \).
      iii. ReturnIfAbrupt(kPresent).
      iv. If kPresent is true, then
          1. Let accumulator be the result of Get\( (O, Pk) \).
          2. ReturnIfAbrupt(accumulator).
      v. Decrease \( k \) by 1.
    c. If kPresent is false, throw a TypeError exception.
11. Repeat, while \( k \geq 0 \)
    a. Let Pk be ToString\( (k) \).
    b. Let kPresent be the result of HasProperty\( (O, Pk) \).
    c. ReturnIfAbrupt(kPresent).
    d. If kPresent is true, then
      i. Let kValue be the result of Get\( (O, Pk) \).
ii. ReturnIfAbrupt(kValue).

iii. Let accumulator be the result of calling the [[Call]] internal method of callbackFn with undefined as thisArgument and a List containing accumulator, kValue, k, and O as argumentsList.

iv. ReturnIfAbrupt(accumulator).

v. Decrease k by 1.

12. Return accumulator.

The length property of the reduceRight method is 1.

NOTE The reduceRight function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the reduceRight function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.20 Array.prototype.reverse ( )

The elements of the array are rearranged so as to reverse their order. The object is returned as the result of the call.

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenVal be the result of Get(O, "length").
4. Let len be ToLength(lenVal).
5. ReturnIfAbrupt(len).
6. Let middle be 0.
7. Let lower be 0.
8. Repeat, while lower + middle < len
   a. Let upper be len – lower – 1.
   b. Let upperP be ToLength(upper).
   c. Let lowerP be ToLength(lower).
   d. Let lowerValue be the result of Get(O, lowerP).
   e. ReturnIfAbrupt(lowerValue).
   f. Let upperValue be the result of Get(O, upper).
   g. ReturnIfAbrupt(upperValue).
   h. Let lowerExists be the result of HasProperty(O, lowerP).
   i. ReturnIfAbrupt(lowerExists).
   j. Let upperExists be the result of HasProperty(O, upperP).
   k. ReturnIfAbrupt(upperExists).
   l. If lowerExists is true and upperExists is true, then
      i. Let putStatus be the result of Put(O, lowerP, upperValue, true).
      ii. ReturnIfAbrupt(putStatus).
      iii. Let putStatus be the result of Put(O, lowerP, lowerValue, true).
      iv. ReturnIfAbrupt(putStatus).
   m. Else if lowerExists is false and upperExists is true, then
      i. Let putStatus be the result of Put(O, lowerP, upperValue, true).
      ii. ReturnIfAbrupt(putStatus).
      iii. Let deleteStatus be the result of DeletePropertyOrThrow (O, upperP).
      iv. ReturnIfAbrupt(deleteStatus).
   n. Else if lowerExists is true and upperExists is false, then
      i. Let deleteStatus be the result of DeletePropertyOrThrow (O, lowerP).
      ii. ReturnIfAbrupt(deleteStatus).
      iii. Let putStatus be the result of Put(O, upperP, lowerValue, true).
      iv. ReturnIfAbrupt(putStatus).
   o. Else both lowerExists and upperExists are false,
      i. No action is required.
      p. Increase lower by 1.
9. Return O.

NOTE The reverse function is intentionally generic; it does not require that its this value be an Array object. Therefore, it can be transferred to other kinds of objects for use as a method. Whether the reverse function can be applied successfully to an exotic object that is not an Array is implementation-dependent.
22.1.3.21 Array.prototype.shift()

The first element of the array is removed from the array and returned.

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenVal be the result of Get(O, "length").
4. Let len be ToLength(lenVal).
5. ReturnIfAbrupt(len).
6. If len is zero, then
   a. Let putStatus be the result of Put(O, "length", 0, true).
   b. ReturnIfAbrupt(putStatus).
   c. Return undefined.
7. Let first be the result of Get(O, "0").
8. ReturnIfAbrupt(first).
9. Let k be 1.
10. Repeat, while k ≤ len
    a. Let from be ToString(k).
    b. Let to be ToString(k−1).
    c. Let fromPresent be the result of HasProperty(O, from).
    d. ReturnIfAbrupt(fromPresent).
    e. If fromPresent is true, then
       i. Let fromVal be the result of Get(O, from).
       ii. ReturnIfAbrupt(fromVal).
       iii. Let putStatus be the result of Put(O, to, fromVal, true).
       iv. ReturnIfAbrupt(putStatus).
    f. Else fromPresent is false,
       i. Let deleteStatus be the result of DeletePropertyOrThrow(O, to).
       ii. ReturnIfAbrupt(deleteStatus).
    g. Increase k by 1.
11. Let deleteStatus be the result of DeletePropertyOrThrow(O, ToString(len−1)).
12. ReturnIfAbrupt(deleteStatus).
13. Let putStatus be the result of Put(O, "length", len−1, true).
14. ReturnIfAbrupt(putStatus).
15. Return first.

NOTE The shift function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the shift function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.22 Array.prototype.slice(start, end)

The slice method takes two arguments, start and end, and returns an array containing the elements of the array from element start up to, but not including, element end (or through the end of the array if end is undefined). If start is negative, it is treated as length+start where length is the length of the array. If end is negative, it is treated as length-end where length is the length of the array. The following steps are taken:

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let A be the result of the abstract operation ArrayCreate with argument 0.
4. Let lenVal be the result of Get(O, "length").
5. Let len be ToLength(lenVal).
6. ReturnIfAbrupt(len).
7. Let relativeStart be ToInteger(start).
8. ReturnIfAbrupt(relativeStart).
9. If relativeStart is negative, let k be max((len + relativeStart),0); else let k be min(relativeStart, len).
10. If end is undefined, let relativeEnd be len; else let relativeEnd be ToInteger(end).
11. ReturnIfAbrupt(relativeEnd).
12. If relativeEnd is negative, let final be max((len + relativeEnd),0); else let final be min(relativeEnd, len).
13. Let count be final – k.
14. Let A be undefined.
15. If O is an exotic Array object, then
   a. Let C be the result of Get(O, "constructor").
   b. ReturnIfAbrupt(C).
   c. If IsConstructor(C) is true, then
      i. Let A be the result of OrdinaryConstruct(C, (count)).
16. If A is undefined, then
   a. Let A be the result of the abstract operation ArrayCreate with argument count.
17. ReturnIfAbrupt(A).
18. Let n be 0.
19. Repeat, while k < final
   a. Let Pk be ToString(k).
   b. Let kPresent be the result of HasProperty(O, Pk).
   c. ReturnIfAbrupt(kPresent).
   d. If kPresent is true, then
      i. Let kValue be the result of Get(O, Pk).
      ii. ReturnIfAbrupt(kValue).
      iii. Let status be the result of CreateOwnDataProperty(A, ToString(n), kValue).
      iv. ReturnIfAbrupt(status).
      v. If status is false, throw a TypeError exception.
   e. Increase k by 1.
   f. Increase n by 1.
20. Let putStatus be the result of Put(A, “length”, n, true).
21. ReturnIfAbrupt(putStatus).
22. Return A.

The length property of the slice method is 2.

NOTE 1 The explicit setting of the length property of the result Array in step 15 is necessary to ensure that its value
is correct in situations where the trailing elements of the result Array are not present.

NOTE 2 The slice function is intentionally generic; it does not require that its this value be an Array object. Therefore
it can be transferred to other kinds of objects for use as a method. Whether the slice function can be applied
successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.23 Array.prototype.some ( callbackfn [, thisArg ] )
callbackfn should be a function that accepts three arguments and returns a value that is coercible to the
Boolean value true or false. some calls callbackfn once for each element present in the array, in ascending
order, until it finds one where callbackfn returns true. If such an element is found, some immediately returns
true. Otherwise, some returns false. callbackfn is called only for elements of the array which actually exist; it is
called for missing elements of the array.

If a thisArg parameter is provided, it will be used as the this value for each invocation of callbackfn. If it is not
provided, undefined is used instead.

callbackfn is called with three arguments: the value of the element, the index of the element, and the object
being traversed.

some does not directly mutate the object on which it is called but the object may be mutated by the calls to
callbackfn.

The range of elements processed by some is set before the first call to callbackfn. Elements that are appended
to the array after the call to some begins will not be visited by callbackfn. If existing elements of the array are
changed, their value as passed to callbackfn will be the value at the time that some visits them; elements that
are deleted after the call to some begins and before being visited are not visited. some acts like the “exists”
quantifier in mathematics. In particular, for an empty array, it returns false.
When the `some` method is called with one or two arguments, the following steps are taken:

1. Let `O` be the result of calling `ToObject` passing the `this` value as the argument.
2. ReturnIfAbrupt(`O`).
3. Let `lenValue` be the result of `Get(O, "length")`.
4. Let `len` be `ToLength(lenValue)`.
5. ReturnIfAbrupt(`len`).
6. If `IsCallable(callbackfn)` is false, throw a `TypeError` exception.
7. If `thisArg` was supplied, let `T` be `thisArg`; else let `T` be `undefined`.
8. Let `k` be 0.
9. Repeat, while `k < len`
   a. Let `Pk` be `ToString(k)`.
   b. Let `kPresent` be the result of `HasProperty(O, Pk)`.
   c. ReturnIfAbrupt(`kPresent`).
   d. If `kPresent` is true, then
      i. Let `kValue` be the result of `Get(O, Pk)`.
      ii. ReturnIfAbrupt(`kValue`).
      iii. Let `testResult` be the result of calling the `[[Call]]` internal method of `callbackfn` with `T` as `thisArgument` and a List containing `kValue`, `k`, and `O` as `argumentsList`.
      iv. ReturnIfAbrupt(`testResult`).
      v. If `ToBoolean(testResult)` is true, return true.
   e. Increase `k` by 1.
10. Return false.

The `length` property of the `some` method is 1.

**NOTE** The `some` function is intentionally generic; it does not require that its `this` value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the `some` function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.24 `Array.prototype.sort(comparefn)`

The elements of this array are sorted. The sort is not necessarily stable (that is, elements that compare equal do not necessarily remain in their original order). If `comparefn` is not `undefined`, it should be a function that accepts two arguments `x` and `y` and returns a negative value if `x < y`, zero if `x = y`, or a positive value if `x > y`.

Let `obj` be the result of calling `ToObject` passing the `this` value as the argument.

Let `len` be the result of applying `Uint32` to the result of `Get(obj, "length")`.

If `comparefn` is not `undefined` and is not a consistent comparison function for the elements of this array (see below), the behaviour of `sort` is implementation-defined.

Let `proto` be the result of calling the `[[GetInheritance]]` internal method of `obj`. If `proto` is not `null` and there exists an integer `j` such that all of the conditions below are satisfied then the behaviour of `sort` is implementation-defined:

- `obj` is sparse (22.1)
- `0 ≤ j < len`
- The result of `HasProperty(proto, ToString(j))` is true.

The behaviour of `sort` is also implementation defined if `obj` is sparse and any of the following conditions are true:

- The result of the predicate `IsExtensible(obj)` is false.
- Any array index property of `obj` whose name is a nonnegative integer less than `len` is a data property whose `[[Configurable]]` attribute is false.
The behaviour of `sort` is also implementation defined if any array index property of `obj` whose name is a nonnegative integer less than `len` is an accessor property or is a data property whose `[[Writable]]` attribute is false.

Otherwise, the following steps are taken.

1. Perform an implementation-dependent sequence of calls to the `[[Get]]` and `[[Set]]` internal methods of `obj`, to the `DeletePropertyOrThrow` abstract operation with `obj` as the first argument, and to `SortCompare` (described below), where the property key argument for each call to `[[Get]]`, `[[Set]]`, or `DeletePropertyOrThrow` is the string representation of a nonnegative integer less than `len` and where the arguments for calls to `SortCompare` are results of previous calls to the `[[Get]]` internal method. If `obj` is not sparse then `DeletePropertyOrThrow` must not be called. If any `[[Set]]` call returns `false` a `TypeError` exception is thrown. If an abrupt completion is returned from any of these operations, it is immediately returned as the value of this function.

2. Return `obj`.

The returned object must have the following two properties.

- There must be some mathematical permutation \( \pi \) of the nonnegative integers less than `len`, such that for every nonnegative integer \( j \) less than `len`, if property \( \text{old}[\pi(j)] \) existed, then \( \text{new}[\pi(j)] \) is exactly the same value as \( \text{old}[j] \). But if property \( \text{old}[j] \) did not exist, then \( \text{new} \[\pi(j)] \) does not exist.
- Then for all nonnegative integers \( j \) and \( k \), each less than `len`, if \( \text{SortCompare}(j, k) < 0 \) (see `SortCompare` below), then \( \pi(j) < \pi(k) \).

Here the notation \( \text{old}[j] \) is used to refer to the hypothetical result of calling the `[[Get]]` internal method of `obj` with argument \( j \) before this function is executed, and the notation \( \text{new}[j] \) to refer to the hypothetical result of calling the `[[Get]]` internal method of `obj` with argument \( j \) after this function has been executed.

A function `comparefn` is a consistent comparison function for a set of values \( S \) if all of the requirements below are met for all values \( a \), \( b \), and \( c \) (possibly the same value) in the set \( S \): The notation \( a <_{S} b \) means \( \text{comparefn}(a, b) < 0 \); \( a =_{S} b \) means \( \text{comparefn}(a, b) = 0 \) (of either sign); and \( a >_{S} b \) means \( \text{comparefn}(a, b) > 0 \).

- Calling `comparefn(a, b)` always returns the same value \( v \) when given a specific pair of values \( a \) and \( b \) as its two arguments. Furthermore, \( \text{Type}(v) \) is `Number`, and \( v \) is not `NaN`. Note that this implies that exactly one of the following is true.
  - \( a <_{S} b \), \( a =_{S} b \), or \( a >_{S} b \) will be true for a given pair of \( a \) and \( b \).
  - `comparefn(a, b)` does not modify \( a \) or \( b \).
  - \( a =_{S} a \) (reflexivity)
  - If \( a =_{S} b \), then \( b =_{S} a \) (symmetry)
  - If \( a <_{S} b \) and \( b =_{S} c \), then \( a =_{S} c \) (transitivity of \( =_{S} \))
  - If \( a <_{S} b \) and \( b <_{S} c \), then \( a <_{S} c \) (transitivity of \( <_{S} \))
  - If \( a >_{S} b \) and \( b >_{S} c \), then \( a >_{S} c \) (transitivity of \( >_{S} \))

**NOTE** The above conditions are necessary and sufficient to ensure that `comparefn` divides the set \( S \) into equivalence classes and that these equivalence classes are totally ordered.

**Runtime Semantics: SortCompare Abstract Operation**

When the `SortCompare` abstract operation is called with two arguments \( j \) and \( k \), the following steps are taken:

1. Let `jString` be `ToString(j)`.
2. Let `kString` be `ToString(k)`.
3. Let `jHas` be the result of `HasProperty(obj, jString)`.
4. ReturnIfAbrupt(`jHas`).
5. Let `kHas` be the result of `HasProperty(obj, kString)`.
6. ReturnIfAbrupt(`kHas`).
7. If `jHas` and `kHas` are both `true`, then return \( +0 \).
8. If `jHas` is `false`, then return `1`.
9. If `kHas` is `false`, then return `−1`.
10. Let `x` be the result of `Get(obj, jString)`.

11. ReturnIfAbrupt(x).
12. Let y be the result of Get(obj, kString).
13. ReturnIfAbrupt(y).
14. If x and y are both undefined, return +0.
15. If x is undefined, return 1.
16. If y is undefined, return −1.
17. If the argument comparefn is not undefined, then
   a. If IsCallable(comparefn) is false, throw a TypeError exception.
   b. Return the result of calling the [[Call]] internal method of comparefn passing undefined as thisArgument and with a List containing the values of x and y as the argumentsList.
18. Let xString be ToString(x).
19. ReturnIfAbrupt(xString).
20. Let yString be ToString(y).
21. ReturnIfAbrupt(yString).
22. If xString < yString, return −1.
23. If xString > yString, return 1.
24. Return +0.

NOTE 1 Because non-existent property values always compare greater than undefined property values, and undefined always compares greater than any other value, undefined property values always sort to the end of the result, followed by non-existent property values.

NOTE 2 The sort function is intentionally generic; it does not require that its this value be an Array object. Therefore, it can be transferred to other kinds of objects for use as a method. Whether the sort function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.25 Array.prototype.splice (start, deleteCount [ , item1 [ , item2 [ , … ] ] ])

When the splice method is called with two or more arguments start, deleteCount and (optionally) item1, item2, etc., the deleteCount elements of the array starting at integer index start are replaced by the arguments item1, item2, etc. An Array object containing the deleted elements (if any) is returned. The following steps are taken:

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenVal be Get(O, "length").
4. Let len be ToLength(lenVal).
5. ReturnIfAbrupt(len).
6. Let relativeStart be ToInteger(start).
7. ReturnIfAbrupt(relativeStart).
8. If relativeStart is negative, let actualStart be max((len + relativeStart),0); else let actualStart be min(relativeStart, len).
9. If deleteCount is not present, then
   a. Let actualDeleteCount be len + actualStart
10. Else,
   a. Let dc be ToInteger(deleteCount).
   b. ReturnIfAbrupt(dc).
   c. Let actualDeleteCount be min(max(dc,0), len − actualStart).
11. Let count be (actualStart × dc).
12. Let A be undefined.
13. If O is an exotic Array object, then
   a. Let C be the result of Get(O, "constructor").
   b. ReturnIfAbrupt(C).
   c. If IsConstructor(C) is true, then
      i. Let A be the result of OrdinaryConstruct(C, {actualDeleteCount: dc}).
14. If A is undefined, then
   a. Let A be the result of the abstract operation ArrayCreate with argument actualDeleteCount.
15. ReturnIfAbrupt(A).
16. Let k be 0.
17. Repeat, while k < actualDeleteCount
   a. Let from be ToString(actualStart+k).
b. Let fromPresent be the result of HasProperty(O, from).

c. ReturnIfAbrupt(fromPresent).

d. If fromPresent is true, then

  i. Let fromValue be the result of Get(O, from).
  ii. ReturnIfAbrupt(fromValue).
  iii. Call the [[DefineOwnProperty]] internal method of A with arguments ToString(k) and Property Descriptor {
      "[[Value]]": fromValue, "[[Writable]]": true, "[[Enumerable]]": true, "[[Configurable]]": true
     }.
  e. Increment k by 1.

18. Let putStatus be the result of Put(A, \"length\", actualDeleteCount, true).

19. ReturnIfAbrupt(putStatus).

20. Let items be an internal List whose elements are, in left to right order, the portion of the actual argument list starting with item1. The list will be empty if no such items are present.

21. Let itemCount be the number of elements in items.

22. If itemCount < actualDeleteCount, then

   a. Let k be actualStart.
   b. Repeat, while k < (len – actualDeleteCount)
      i. Let from be ToString(k+actualDeleteCount).
      ii. Let to be ToString(k+itemCount).
      iii. Let fromPresent be the result of HasProperty(O, from).
      iv. ReturnIfAbrupt(fromPresent).
      v. If fromPresent is true, then
         1. Let fromValue be the result of Get(O, from).
         2. ReturnIfAbrupt(fromValue).
         3. Let putStatus be the result of Put(O, to, fromValue, true).
         4. ReturnIfAbrupt(putStatus).
      vi. Else fromPresent is false,
         1. Let deleteStatus be the result of DeletePropertyOrThrow(O, to).
         2. ReturnIfAbrupt(deleteStatus).
         vii. Increase k by 1.
   c. Let k be len – 1.
   d. Repeat, while k > (len – actualDeleteCount + itemCount)
      i. Let deleteStatus be the result of DeletePropertyOrThrow(O, ToString(k–1)).
      ii. ReturnIfAbrupt(deleteStatus).
      iii. Decrease k by 1.

23. Else if itemCount > actualDeleteCount, then

   a. Let k be (len – actualDeleteCount).
   b. Repeat, while k > actualStart
      i. Let from be ToString(k + actualDeleteCount – 1).
      ii. Let to be ToString(k + itemCount – 1).
      iii. Let fromPresent be the result of HasProperty(O, from).
      iv. ReturnIfAbrupt(fromPresent).
      v. If fromPresent is true, then
         1. Let fromValue be the result of Get(O, from).
         2. ReturnIfAbrupt(fromValue).
         3. Let putStatus be the result of Put(O, to, fromValue, true).
         4. ReturnIfAbrupt(putStatus).
      vi. Else fromPresent is false,
         1. Let deleteStatus be the result of DeletePropertyOrThrow(O, to).
         2. ReturnIfAbrupt(deleteStatus).
         vii. Decrease k by 1.

24. Let k be actualStart.

25. Repeat, while items is not empty

   a. Remove the first element from items and let E be the value of that element.
   b. Let putStatus be the result of Put(O, ToString(k), E, true).
   c. ReturnIfAbrupt(putStatus).
   d. Increase k by 1.

26. Let putStatus be the result of Put(O, \"length\", len – actualDeleteCount + itemCount, true).

27. ReturnIfAbrupt(putStatus).

28. Return A.
The `length` property of the `splice` method is 2.

NOTE 1 The explicit setting of the `length` property of the result Array in step 13 is necessary to ensure that its value is correct in situations where its trailing elements are not present.

NOTE 2 The `splice` function is intentionally generic; it does not require that its `this` value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the `splice` function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.26 Array.prototype.toLocaleString ()

The elements of the array are converted to Strings using their `toLocaleString` methods, and these Strings are then concatenated, separated by occurrences of a separator String that has been derived in an implementation-defined locale-specific way. The result of calling this function is intended to be analogous to the result of `toString`, except that the result of this function is intended to be locale-specific.

The result is calculated as follows:

1. Let `array` be the result of calling ToObject passing the `this` value as the argument.
2. ReturnIfAbrupt(array).
3. Let `arrayLen` be the result of Get(array, "length").
4. Let `len` be ToLength(arrayLen).
5. ReturnIfAbrupt(len).
6. Let `separator` be the String value for the list-separator String appropriate for the host environment’s current locale (this is derived in an implementation-defined way).
7. If `len` is zero, return the empty String.
8. Let `firstElement` be the result of Get(array, "0").
9. ReturnIfAbrupt(firstElement).
10. If `firstElement` is undefined or null, then
   a. Let `R` be the empty String.
   11. Else
   a. Let `R` be the result of Invoke(firstElement, "toLocaleString").
   b. Let `R` be ToString(R).
   c. ReturnIfAbrupt(R).
12. Let `k` be 1.
13. Repeat, while `k` < `len`
   a. Let `S` be a String value produced by concatenating `R` and `separator`.
   b. Let `nextElement` be the result of Get(array, ToString(k)).
   c. ReturnIfAbrupt(nextElement).
   d. If `nextElement` is undefined or null, then
      i. Let `R` be the empty String.
   e. Else
      i. Let `R` be the result of Invoke(nextElement, "toLocaleString").
   f. Let `R` be a String value produced by concatenating `S` and `R`.
   g. Increase `k` by 1.

NOTE 1 The first parameter to this function is likely to be used in a future version of this standard; it is recommended that implementations do not use this parameter position for anything else.

NOTE 2 The `toLocaleString` function is intentionally generic; it does not require that its `this` value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the `toLocaleString` function can be applied successfully to an exotic object that is not an Array is implementation-dependent.

22.1.3.27 Array.prototype.toString ()

When the `toString` method is called, the following steps are taken:
1. Let \( array \) be the result of calling ToObject on the \( \text{this} \) value.
2. ReturnIfAbrupt(\( array \)).
3. Let \( \text{func} \) be the result of Get(\( array \), \"join\")).
4. ReturnIfAbrupt(\( \text{func} \)).
5. If IsCallable(\( \text{func} \)) is false, then let \( \text{func} \) be the standard built-in method Object.prototype.toString (19.1.4.6).
6. Return the result of calling the [[Call]] internal method of \( \text{func} \) providing array as \( \text{thisArgument} \) and an empty List as argumentsList.

NOTE The toString function is intentionally generic; it does not require that its \( \text{this} \) value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the toString function can be applied successfully to a exotic object that is not an Array is implementation-dependent.

22.1.3.28 Array.prototype.unshift ([item1 [, item2 [, … ]]])

The arguments are prepended to the start of the array, such that their order within the array is the same as the order in which they appear in the argument list.

When the unshift method is called with zero or more arguments \( \text{item1}, \text{item2}, \text{etc.} \), the following steps are taken:

1. Let \( O \) be the result of calling ToObject passing the \( \text{this} \) value as the argument.
2. ReturnIfAbrupt(\( O \)).
3. Let \( \text{lenVal} \) be the result of Get(\( O \), \"length\")
4. Let \( \text{len} \) be ToLength(\( \text{lenVal} \)).
5. ReturnIfAbrupt(\( \text{len} \)).
6. Let \( \text{argCount} \) be the number of actual arguments.
7. Let \( k \) be \( \text{len} \).
8. Repeat, while \( k > 0 \):
   a. Let \( \text{from} \) be ToString(\( k-1 \)).
   b. Let \( \text{to} \) be ToString(\( k+\text{argCount} -1 \)).
   c. Let \( \text{fromPresent} \) be the result of HasProperty(\( O \), \( \text{from} \)).
   d. ReturnIfAbrupt(\( \text{fromPresent} \)).
   e. If fromPresent is true, then
      i. Let \( \text{fromValue} \) be the result of Get(\( O \), \( \text{from} \)).
      ii. ReturnIfAbrupt(\( \text{fromValue} \)).
      iii. Let \( \text{putStatus} \) be the result of Put(\( O \), \( \text{to} \), \( \text{fromValue} \), \( \text{true} \)).
      iv. ReturnIfAbrupt(\( \text{putStatus} \)).
   f. Else fromPresent is false.
      i. Let \( \text{deleteStatus} \) be the result of DeletePropertyOrThrow(\( O \), \( \text{to} \)).
      ii. ReturnIfAbrupt(\( \text{deleteStatus} \)).
   g. Decrease \( k \) by 1.
9. Let \( j \) be 0.
10. Let \( \text{items} \) be an internal List whose elements are, in left to right order, the arguments that were passed to this function invocation.
11. Repeat, while \( \text{items} \) is not empty
   a. Remove the first element from \( \text{items} \) and let \( E \) be the value of that element.
   b. Let \( \text{putStatus} \) be the result of Put(\( O \), \( \text{ToString}(j) \), \( E \), \( \text{true} \)).
   c. ReturnIfAbrupt(\( \text{putStatus} \)).
   d. Increase \( j \) by 1.
12. Let \( \text{putStatus} \) be the result of Put(\( O \), \"length\", \( \text{len}+\text{argCount} \), \( \text{true} \)).
13. Return \( \text{len}+\text{argCount} \).

The length property of the unshift method is 1.

NOTE The unshift function is intentionally generic; it does not require that its \( \text{this} \) value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method. Whether the unshift function can be applied successfully to an exotic object that is not an Array is implementation-dependent.
22.1.3.29 Array.prototype.values( )

The following steps are taken:

1. Let O be the result of calling ToObject with the this value as its argument.
2. ReturnIfAbrupt(O).
3. Return the result of calling the CreateArrayIterator abstract operation with arguments O and "value".

22.1.3.30 Array.prototype[@@iterator]()

The initial value of the @@iterator property is the same function object as the initial value of the Array.prototype.values property.

22.1.3.31 Array.prototype[@@unscopables]

The initial value of the @@unscopables data property is an object created by the following steps:

1. Let blacklist be the result of calling ArrayCreate(5, %ArrayPrototype%).
2. Call CreateOwnDataProperty(blacklist, "0", "find").
3. Call CreateOwnDataProperty(blacklist, "1", "findIndex").
4. Call CreateOwnDataProperty(blacklist, "2", "fill").
5. Call CreateOwnDataProperty(blacklist, "3", "copyWithin").
6. Call CreateOwnDataProperty(blacklist, "4", "entries").
7. Call CreateOwnDataProperty(blacklist, "5", "keys").
8. Call CreateOwnDataProperty(blacklist, "6", "values").

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

NOTE The elements of this array are property names that were not included as standard properties of Array.prototype prior to the sixth edition of this specification. These names are ignored for with statement binding purposes in order to preserve the behaviour of existing code that might use one of these names as a binding in an outer scope that is shadowed by a with statement whose binding object is an Array object.

22.1.4 Properties of Array Instances

Array instances are exotic Array objects and have the internal methods specified for such objects. Array instances inherit properties from the Array prototype object. Array instances also have an [[ArrayInitialisationState]] internal data property.

Array instances have a length property, and a set of enumerable properties with array index names.

22.1.4.1 length

The length property of this Array object is a data property whose value is always numerically greater than the name of every deletable property whose name is an array index.

The length property initially has the attributes { [[Writable]]: true, [[Enumerable]]: false, [[Configurable]]: false }.  

NOTE Attempting to set the length property of an Array object to a value that is numerically less than or equal to the largest numeric property name of an existing array indexed non-deletable property of the array will result in the length being set to a numeric value that is one greater than that largest numeric property name. See 9.2.2.1.

22.1.5 Array Iterator Object Structure

An Array Iterator is an object, with the structure defined below, that represents a specific iteration over some specific Array instance object. There is not a named constructor for Array Iterator objects. Instead, Array iterator objects are created by calling certain methods of Array instance objects.
22.1.5.1 CreateArrayIterator Abstract Operation

Several methods of Array objects return Iterator objects. The abstract operation CreateArrayIterator with arguments array and kind is used to create such Iterator objects. It performs the following steps:

1. Let O be the result of calling ToObject(array).
2. ReturnIfAbrupt(O).
3. Let iterator be the result of ObjectCreate(%ArrayIteratorPrototype%, (][[IteratedObject]], [[ArrayIteratorNextIndex]], [[ArrayIterationKind]])).
4. Set iterator’s [[IteratedObject]] internal data property to O.
5. Set iterator’s [[ArrayIteratorNextIndex]] internal data property to 0.
6. Set iterator’s [[ArrayIterationKind]] internal data property to kind.
7. Return iterator.

22.1.5.2 The Array Iterator Prototype

All Array Iterator Objects inherit properties from a common Array Iterator Prototype object. The [[Prototype]] internal data property of the Array Iterator Prototype is the %ObjectPrototype% intrinsic object. In addition, the Array Iterator Prototype has the following properties:

22.1.5.2.1 Array.prototype.constructor

22.1.5.2.2 Array.prototype.next()

1. Let O be the this value.
2. If Type(O) is not Object, throw a TypeError exception.
3. If O does not have all of the internal properties of a Array Iterator Instance (22.1.5.3), throw a TypeError exception.
4. Let a be the value of the [[IteratedObject]] internal data property of O.
5. Let index be the value of the [[ArrayIteratorNextIndex]] internal data property of O.
6. Let itemKind be the value of the [[ArrayIterationKind]] internal data property of O.
7. Let lenValue be the result of Get(a, "length").
8. Let len be ToLength(lenValue).
9. ReturnIfAbrupt(len).
10. If itemKind contains the substring "sparse", then
    a. Let found be false.
    b. Repeat, while found is false and index < len
        i. Let elementKey be ToString(index).
        ii. Let found be the result of HasProperty(a, elementKey).
        iii. ReturnIfAbrupt(found).
        iv. If found is false, then
            1. Increase index by 1.
11. If index ≥ len, then
    a. Set the value of the [[ArrayIteratorNextIndex]] internal data property of O to +∞.
12. Return CreateItrResultObject(undefined, true). Set the value of the [[ArrayIteratorNextIndex]] internal data property of O to index+1.
13. If itemKind contains the substring "value", then
    a. Let elementKey be ToString(index).
    b. Let elementValue be the result of Get(a, elementKey).
    c. ReturnIfAbrupt(elementValue).
14. If itemKind contains the substring "key+value", then
    a. Let result be the result of the abstract operation ArrayCreate with argument 2.
    b. Assert: result is a new, well-formed Array object so the following operations will never fail.
    c. Call the [[DefineOwnProperty]] internal method of result with arguments "0" and Property Descriptor (][[Value]], index, [[Writable]], true, [[Enumerable]], true, [[Configurable]], true).
    d. Call the [[DefineOwnProperty]] internal method of result with arguments "1" and Property Descriptor (][[Value]], elementValue, [[Writable]], true, [[Enumerable]], true, [[Configurable]], true).
    e. Return CreateItrResultObject(result, false).

Commented [AWB10154]: 1.1.1.1.1.TODO: need to decide what to use for a constructor for these sort of objects.

Commented [AWB15155]: We don't current have a public API for requesting a sparse iteration. If that remains the case we can delete this clause.
15. Else if `itemKind` contains the substring "key" then, return CreateItrResultObject(index, false).
16. Assert: `itemKind` contains the substring "value".
17. Return CreateItrResultObject(elementValue, false).

22.1.5.2.3 `ArrayIterator.prototype @@iterator` ( )

The following steps are taken:

1. Return the `this` value.

22.1.5.2.4 `ArrayIterator.prototype @@toStringTag`

The initial value of the `@@toStringTag` property is the string value "Array Iterator".

22.1.5.3 Properties of Array Iterator Instances

Array iterator instances inherit properties from the Array Iterator prototype (the intrinsic, `%ArrayIteratorPrototype%`). Array iterator instances are initially created with the internal properties listed in Table 35.

Table 35 — Internal Data Properties of Array Iterator Instances

<table>
<thead>
<tr>
<th>Internal Data Property Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[IteratedObject]</code></td>
<td>The object whose array elements are being iterated.</td>
</tr>
<tr>
<td><code>[ArrayIteratorNextIndex]</code></td>
<td>The integer index of the next array index to be examined by this iteration.</td>
</tr>
<tr>
<td><code>[ArrayIterationKind]</code></td>
<td>A string value that identifies what is to be returned for each element of the iteration. The possible values are: &quot;key&quot;, &quot;value&quot;, &quot;key+value&quot;, &quot;sparse: key&quot;, &quot;sparse: value&quot;, &quot;sparse: key+value&quot;.</td>
</tr>
</tbody>
</table>

22.2 TypedArray Objects

TypedArray objects present an array-like view of an underlying binary data buffer. Each element of a TypedArray instance has the same underlying binary scalar data type. There is a distinct TypedArray constructor for each of the nine supported element types. For each constructor in Table 36 is a distinct TypedArray constructor object with a corresponding prototype object and instances.
### Table 36 – The TypedArray Constructors

<table>
<thead>
<tr>
<th>Constructor Name</th>
<th>Element Type</th>
<th>Element Size</th>
<th>Conversion Operation</th>
<th>Description</th>
<th>Equivalent C Type</th>

<td>Float</td>
</tr>
<tr>
<td>Float64Array</td>
<td>Float64</td>
<td>8</td>
<td>ToFloat64</td>
<td>64-bit IEEE floating point</td>
<td>Double</td>
</tr>
</tbody>
</table>

In the definitions below, references to TypedArray should be replaced with the appropriate constructor name from the above table. The phrase “the element size in bytes” refers to the value in the Element Size column of the table in the row corresponding to the constructor. The phrase “element Type” refers to the value in the Element Type column for that row.

#### 22.2.1 The %TypedArray% Intrinsic Object

The %TypedArray% intrinsic object is a constructor-like function object that all of the TypedArray constructor object inherit from. %TypedArray% and its corresponding prototype object provide common properties that are inherited by all TypeArray constructors and their instances. The %TypedArray% intrinsic does not have a global name or appear as a property of the global object.

However, if the this value passed in the call is an Object with an [[ViewedArrayBuffer]] internal data property whose value is undefined, it initializes the this value using the argument values. This permits super invocation of the TypedArray constructors by TypedArray subclasses.

The %TypedArray% intrinsic function object is designed to act as the superclass of the various TypedArray constructors. Those constructors use %TypedArray% to initialize their instances by invoking %TypedArray% as if by making a super call. The %TypedArray% intrinsic function is not designed to be directly called in any other way. If %TypedArray% is directly called or called as part of a new expression an exception is thrown.

The actual behaviour of a super call of %TypedArray% depends upon the number and kind of arguments that are passed to it.

#### 22.2.1.1 %TypedArray% ( length )

This description applies if and only when %TypedArray% function is called and the Type of the first argument is not Object.

%TypedArray% called with argument length performs the following steps:

1. Assert: Type(length) is not Object.
2. Let O be the this value.
3. If Type(O) is not Object or if O does not have an [[ViewedArrayBuffer]] internal data property or if the value of O’s [[ViewedArrayBuffer]] internal data property is not undefined, then
   a. Throw a TypeError exception.
4. If O does not have an [[TypedArrayName]] internal data property, then throw a TypeError exception.
5. Let constructorName be the string value O’s [[TypedArrayName]] internal data property.
6. Let $elementType$ be the string value of the Element Type value in Table 36 for $constructorName$.
7. Let $numberLength$ be ToNumber($length$).
8. Let $elementLength$ be ToInteger($numberLength$).
9. ReturnIfAbrupt($elementLength$).
10. If $numberLength \neq elementLength$ or $elementLength < 0$, then throw a RangeError exception.
11. Let $data$ be the result of calling AllocateArrayBuffer($%ArrayBuffer%$).
12. ReturnIfAbrupt($data$).
13. Let $elementSize$ be the Size Element value in Table 36 for $constructorName$.
14. Let $byteLength$ be $elementSize \times elementLength$.
15. Let $status$ be the result of SetArrayBufferData($data$, $byteLength$).
16. ReturnIfAbrupt($status$).
17. Set $O$’s $%ViewedArrayBuffer%$ to $data$.
18. Set $O$’s $%ByteLength%$ internal data property to $byteLength$.
19. Set $O$’s $%ByteOffset%$ internal data property to $0$.
20. Set $O$’s $%ArrayLength%$ internal data property to $elementLength$.

22.2.1.2 %TypedArray%($typedArray$)

This description applies if and only if the %TypedArray% function is called with at least one argument and the Type of the first argument is Object and that object has a $%ViewedArrayBuffer%$ internal data property.

%TypedArray% called with argument $typedArray$ performs the following steps:

1. Assert: Type($typedArray$) is Object and %typedArray% has a $%ViewedArrayBuffer%$ internal data property.
2. Let $srcArray$ be $typedArray$.
3. Let $O$ be this value.
4. If Type($O$) is not Object or if $O$ does not have an $%ViewedArrayBuffer%$ internal data property, then throw a TypeError exception.
5. If the value of $O$’s $%ViewedArrayBuffer%$ internal data property is not undefined, then throw a TypeError exception.
6. If $O$ does not have an $%TypedArrayName%$ internal data property, then throw a TypeError exception.
7. If the value of srcArray’s $%ViewedArrayBuffer%$ internal data property is undefined, then throw a TypeError exception.
8. Let $constructorName$ be the string value $O$’s $%TypedArrayName%$ internal data property.
9. Let $elementType$ be the string value of the Element Type value in Table 36 for $constructorName$.
10. Let $elementLength$ be the value of srcArray’s $%ArrayLength%$ internal data property.
11. Let $srcName$ be the string value of srcArray’s $%TypedArrayName%$ internal data property.
12. Let $srcType$ be the string value of the Element Type value in Table 36 for srcName.
13. Let $srcData$ be the value of srcArray’s $%ViewedArrayBuffer%$ internal data property.
14. Let $srcByteOffset$ be the value of srcArray’s $%ByteOffset%$ internal data property.
15. Let $data$ be the result of calling $%ArrayBuffer%$([srcData, srcByteOffset, srcType, $elementType$, $elementLength$]).
16. ReturnIfAbrupt($data$).
17. Let $elementSize$ be the Size Element value in Table 36 for $constructorName$.
18. Let $byteLength$ be $elementSize \times elementLength$.
19. Set $O$’s $%ViewedArrayBuffer%$ to $data$.
20. Set $O$’s $%ByteLength%$ internal data property to $byteLength$.
21. Set $O$’s $%ByteOffset%$ internal data property to $0$.
22. Set $O$’s $%ArrayLength%$ internal data property to $elementLength$.
23. Return $O$.

22.2.1.3 %TypedArray%($array$)

This description applies if and only if the %TypedArray% function is called with at least one argument and the Type of first argument is Object and that object does not have either a $%ViewedArrayBuffer%$ or a $%ArrayBufferData%$ internal data property.

%TypedArray% called with argument $array$ performs the following steps:
1. **Assert**: Type(array) is Object and array does not have either a [[ViewedArrayBuffer]] or a [[ArrayBufferData]] internal data property.
2. Let O be the this value.
3. Let srcArray be array.
4. If Type(O) is not Object or if O does not have an [[ViewedArrayBuffer]] internal data property, then throw a **TypeError** exception.
5. If the value of O's [[ViewedArrayBuffer]] internal data property is not **undefined**, then throw a **TypeError** exception.
6. If O does not have an [[TypedArrayName]] internal data property, then throw a **TypeError** exception.
7. Let constructorName be the string value O's [[TypedArrayName]] internal data property.
8. Let elementType be the string value of the Element Type value in Table 36 for constructorName.
9. Let arrayLength be the result of Get(srcArray, "Length").
10. Let elementLength be ToLength(arrayLength).
11. ReturnIfAbrupt(elementLength).
12. If elementLength < 0, then throw a **RangeError** exception.
13. Let data be the result of calling AllocateArrayBuffer(%ArrayBuffer%, elementType).
14. ReturnIfAbrupt(data).
15. Let byteLength be the Size Element value in Table 36 for constructorName.
16. Let buffer be the result of SetArrayBufferData(data, byteLength).
17. Let status be the result of SetArrayBufferData(buffer, byteLength).
18. ReturnIfAbrupt(status).
19. Let k be 0.
20. Repeat, while k < elementLength
   a. Let Pk be ToString(k).
   b. Let kValue be the result of Get(srcArray, Pk).
   c. Let kNumber be ToNumber(kValue).
   d. Perform SetValueInBuffer(data, k × elementSize, elementType, kNumber).
   e. Increase k by 1.
21. Set O's [[ViewedArrayBuffer]] to data.
22. Set O's [[ByteLength]] internal data property to byteLength.
23. Set O's [[ByteOffset]] internal data property to 0.
24. Set O's [[ArrayLength]] internal data property to elementLength.
25. Return O.

**22.2.1.4 %TypedArray% ( buffer, byteOffset=0, length=undefined )**

This description applies if and only if the %TypedArray% function is called with at least one argument and the Type of the first argument is Object and that object has a [[ArrayBufferData]] internal data property.

%TypedArray% called with arguments buffer, byteOffset, and length performs the following steps:

1. **Assert**: Type(buffer) is Object and buffer has a [[ArrayBufferData]] internal data property.
2. Let O be the this value.
3. If the value of buffer’s [[ArrayBufferData]] internal data property is **undefined**, then throw a **TypeError** exception.
4. If Type(O) is not Object or if O does not have an [[ViewedArrayBuffer]] internal data property, then throw a **TypeError** exception.
5. If the value of O’s [[ViewedArrayBuffer]] internal data property is not **undefined**, then throw a **TypeError** exception.
6. If O does not have an [[TypedArrayName]] internal data property, then throw a **TypeError** exception.
7. Let constructorName be the string value O’s [[TypedArrayName]] internal data property.
8. Let elementType be the string value of the Element Type value in Table 36 for constructorName.
9. Let elementSize be the Number value of the Element Size value in Table 36 for constructorName.
10. Let offset be ToInteger(byteOffset).
11. ReturnIfAbrupt(offset).
12. If offset < 0, then throw a **RangeError** exception.
13. If offset modulo elementSize ≠ 0, then throw a **RangeError** exception.
14. Let bufferLength be the value of buffer’s [[ArrayBufferByteLength]] internal data property.
15. If offset + elementSize ≤ bufferLength, then throw a **RangeError** exception.
16. If `length` is `undefined`, then
   a. If `bufferByteLength` modulo `elementSize` ≠ 0, then throw a `RangeError` exception.
   b. Let `newByteLength` be `bufferByteLength – offset`.
17. Else,
   a. Let `newLength` be `ToLength(length)`.
   b. ReturnIfAbrupt(`newLength`).
   c. If `newLength` < 0, then throw a `RangeError` exception.
   d. Let `newByteLength` be `newLength × elementSize`.
   e. If `offset + newByteLength` > `bufferByteLength`, then throw a `RangeError` exception.
18. If the value of O’s [[ViewedArrayBuffer]] internal data property is `undefined`, then throw a `TypeError` exception.
19. Set O’s [[ViewedArrayBuffer]] to `buffer`.
20. Set O’s [[ByteLength]] internal data property to `newByteLength`.
21. Set O’s [[ByteOffset]] internal data property to `offset`.
22. Set O’s [[ArrayLength]] internal data property to `newByteLength / elementSize`.
23. Return O.

22.2.1.5 `%TypedArray%` (all other argument combinations)
If the `%TypedArray%` function is called with arguments that do not match any of the preceding argument descriptions a `TypeError` exception is thrown.

22.2 Properties of the `%TypedArray%` Intrinsic Object
The `%TypedArray%` intrinsic object is a built-in function object. The value of the [[Prototype]] internal data property of `%TypedArray%` is the Function prototype object (19.2.3).

The `%TypedArray%` intrinsic object does not have a [[TypedArrayConstructor]] internal data property.

Besides a `length` property (whose value is 3), `%TypedArray%` has the following properties:

22.2.2.1 `%TypedArray%` from (source, mapfn=undefined, thisArg=undefined)
When the `from` method is called with arguments that do not match any of the preceding argument descriptions a `TypeError` exception is thrown.

1. Let C be the this value.
2. If IsConstructor(C) is false, then throw a `TypeError` exception.
3. Let items be ToObject(source).
4. ReturnIfAbrupt(items).
5. If `mapfn` is `undefined`, then let `mapping` be false.
6. else
   a. If IsCallable(mapfn) is false, throw a `TypeError` exception.
   b. If thisArg was supplied, let T be thisArg, else let T be `undefined`.
   c. Let `mapping` be true
7. Let usingIterator be the result of HasProperty(items, @@Iterator).
8. ReturnIfAbrupt(usingIterator).
9. If usingIterator is true, then
   a. Let `iterator` be the result of performing GetIterator(items).
   b. ReturnIfAbrupt(iterator).
   c. Let `values` be a new empty List.
   d. Let `done` be false
   e. Repeat, while `done` is false
      i. Let `next` be the result of IteratorNext(iterator).
      ii. ReturnIfAbrupt(next).
      iii. Let `done` be IteratorComplete(next).
      iv. ReturnIfAbrupt(done).
      v. If `done` is false, then
         1. Let `nextValue` be IteratorValue(next).
         2. ReturnIfAbrupt(nextValue).
3. Append `nextValue` to the end of the `List values`.
   f. Let `len` be the number of elements in `values`.
   g. Let `newObj` be the result of `OrdinaryConstruct(C, {`len`})`.
   h. ReturnIfAbrupt(`newObj`).
   i. Let `k` be 0.
   j. Repeat, while `k < len`
      i. Let `Pk` be `ToString(k)`.
      ii. Let `kValue` be the result of `Get(items, Pk)`.
      iii. If `mapping is true`, then
          1. Let `mappedValue` be the result of calling the `[[Call]] internal method of mapfn with T as thisArgument and a List containing `kValue` as argumentsList.
          2. ReturnIfAbrupt(`mappedValue`).
      iv. Else, let `mappedValue` be `kValue`.
      v. Let `putStatus` be the result of `Put(`newObj, `Pk, mappedValue, true`)`.
      vi. ReturnIfAbrupt(`putStatus`).
      vii. Increase `k` by 1.
   k. Assert: `values` is now an empty `List`.
   l. Return `newObj`.
   10. Assert: `items` is not an `Iterator` so assume it is `Array-like`.
   11. Let `lenValue` be the result of `Get(items, "length")`.
   12. Let `len` be `ToInteger(lenValue)`.
   13. ReturnIfAbrupt(`len`).
   14. Let `newObj` be the result of `OrdinaryConstruct(C, {`len`})`.
   15. ReturnIfAbrupt(`newObj`).
   16. Let `k` be 0.
   17. Repeat, while `k < len`
      a. Let `Pk` be `ToString(k)`.
      b. Let `kValue` be the result of `Get(items, Pk)`.
      c. ReturnIfAbrupt(`kValue`).
      d. If `mapping is true`, then
          i. Let `mappedValue` be the result of calling the `[[Call]] internal method of mapfn with T as thisArgument and a List containing `kValue` as argumentsList.
          ii. ReturnIfAbrupt(`mappedValue`).
      e. Else, let `mappedValue` be `kValue`.
      f. Let `putStatus` be the result of `Put(`newObj, `Pk, mappedValue, true`)`.
      g. ReturnIfAbrupt(`putStatus`).
      h. Increase `k` by 1.
   18. Return `newObj`.

   NOTE The `from` function is an intentionally generic factory method; it does not require that its `this value` be the `Array constructor`. Therefore it can be transferred to or inherited by any other constructors that may be called with a single numeric argument. This function uses `[Put]` to store elements into a newly created object and assume that the constructor sets the `length` property of the new object to the argument value passed to it.

   22.2.2.2 `%TypedArray%.of ( ...items )`

   When the `%method%` method is called with any number of arguments, the following steps are taken:
   1. Let `lenValue` be the result of `Get(items, "length")`.
   2. Let `len` be `ToInteger(lenValue)`.
   3. Let `C` be the `this value`.
   4. If `IsConstructor(C) is true`, then
      a. Let `newObj` be the result of `OrdinaryConstruct(C, {`len`})`.
   5. Else,
      a. Throw a `TypeError` exception.
   6. ReturnIfAbrupt(`newObj`).
   7. Let `k` be 0.
   8. Repeat, while `k < len`
      a. Let `Pk` be `ToString(k)`.
      b. Let `kValue` be the result of `Get(items, Pk)`.
c. Let defineStatus be the result of Put(newObj,Pk, kValue.[[value]], true).
d. ReturnIfAbrupt(defineStatus).
e. Increase k by 1.
9. Return newObj.

The length property of the of method is 0.

NOTE 1 The items argument is assumed to be a well-formed rest argument value.

NOTE 2 The of function is an intentionally generic factory method; it does not require that its this value be a TypedArray constructor. Therefore it can be transferred to or inherited by other constructors that may be called with a single numeric argument. However, it does assume that constructor creates and initializes a length property that is initialized to its argument value.

22.2.2.3 %TypedArray%.prototype
The initial value of %TypedArray%.prototype is the %TypedArrayPrototype% intrinsic object (22.2.3).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

22.2.2.4 %TypedArray%[@@create]()
The @@create method of %TypedArray% performs the following steps:

1. Let F be the this value.
2. If Type(F) is not Object, then throw a TypeError exception.
3. If F does not have a [[TypedArrayConstructor]] internal data property, then throw a TypeError exception.
4. Let proto be the result of GetPrototypeFromConstructor(F, "%TypedArrayPrototype%").
5. ReturnIfAbrupt(proto).
6. Let obj be the result of calling IntegerIndexedObjectCreate(proto).
7. Add a [[ViewedArrayBuffer]] internal data property to obj and set its initial value to undefined.
8. Add a [[TypedArrayName]] internal data property to obj and set its initial value to the value of F's [[TypedArrayConstructor]] internal data property.
9. Add a [[ByteLength]] internal data property to obj and set its initial value to 0.
10. Add a [[ByteOffset]] internal data property to obj and set its initial value to 0.
11. Add a [[ArrayLength]] internal data property to obj and set its initial value to 0.
12. Call the [[PreventExtensions]] internal method of obj.
13. Return obj.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

22.2.3 Properties of the %TypedArrayPrototype% Object
The value of the [[Prototype]] internal data property of the %TypedArrayPrototype% object is the standard built-in Object prototype object (19.1.4). The %TypedArrayPrototype% object is an ordinary object. It does not have a [[ViewedArrayBuffer]] or any other of the internal data properties that are specific to TypedArray instance objects.

22.2.3.1 get %TypedArray%.prototype.buffer

%TypedArray%.prototype.buffer is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let O be the result of calling ToObject with the this value as its argument.
2. ReturnIfAbrupt(O).
3. If O does not have a [[ViewedArrayBuffer]] internal data property throw a TypeError exception.
4. Let buffer be the value of O's [[ViewedArrayBuffer]] internal data property.
5. If buffer is undefined, then throw a TypeError exception.
6. Return buffer.

Commented [AWB13170]: buffer needs to be an accessor both to comply with WebIDL requirements and to support the Kronos neutering strawman requirements.
22.2.3.2 `get %TypedArray%.prototype.byteLength`

`%TypedArray%.prototype.byteLength` is an accessor property whose set accessor function is `undefined`. Its get accessor function performs the following steps:

1. Let `O` be the result of calling `ToObject` with the `this` value as its argument.
2. ReturnIfAbrupt(`O`).
3. If `O` does not have a `[[ViewedArrayBuffer]]` internal data property throw a `TypeError` exception.
4. Let `buffer` be the value of `O`'s `[[ViewedArrayBuffer]]` internal data property.
5. If `buffer` is `undefined`, then throw a `TypeError` exception.
6. Let `size` be the value of `O`'s `[[ByteLength]]` internal data property.
7. Return `size`.

22.2.3.3 `get %TypedArray%.prototype.byteOffset`

`%TypedArray%.prototype.byteOffset` is an accessor property whose set accessor function is `undefined`. Its get accessor function performs the following steps:

1. Let `O` be the result of calling `ToObject` with the `this` value as its argument.
2. ReturnIfAbrupt(`O`).
3. If `O` does not have a `[[ViewedArrayBuffer]]` internal data property throw a `TypeError` exception.
4. Let `buffer` be the value of `O`'s `[[ViewedArrayBuffer]]` internal data property.
5. If `buffer` is `undefined`, then throw a `TypeError` exception.
6. Let `offset` be the value of `O`'s `[[ByteOffset]]` internal data property.
7. Return `offset`.

22.2.3.4 `%TypedArray%.prototype.constructor`

The initial value of `%TypedArray%.prototype.constructor` is the `%TypedArray%` intrinsic object.

22.2.3.5 `%TypedArray%.prototype.copyWithin (target, start, end = this.length)`

`%TypedArray%.prototype.copyWithin` is a distinct function that implements the same algorithm as `Array.prototype.copyWithin` as defined in 22.1.3.3. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.

The `length` property of the `find` method is 2.

22.2.3.6 `%TypedArray%.prototype.entries ()`

The initial value of the `%TypedArray%.prototype.entries` data property is the same built-in function object as the `Array.prototype.entries` method defined in 22.1.3.4.

22.2.3.7 `%TypedArray%.prototype.every (callbackfn, thisArg = undefined)`

`%TypedArray%.prototype.every` is a distinct function that implements the same algorithm as `Array.prototype.every` as defined in 22.1.3.5. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.

The `length` property of the `every` method is 1.

22.2.3.8 `%TypedArray%.prototype.fill (value, start = 0, end = this.length)`

`%TypedArray%.prototype.fill` is a distinct function that implements the same algorithm as `Array.prototype.fill` as defined in 22.1.3.6. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.
The length property of the `find` method is 1.

22.2.3.9 `%TypedArray%.prototype.filter ( callbackfn, thisArg = undefined )`

The interpretation and use of the arguments of `%TypedArray%.prototype.filter` are the same as for `Array.prototype.filter` as defined in 22.1.3.7.

When the `filter` method is called with one or two arguments, the following steps are taken:

1. Let `O` be the result of calling `ToObject` passing the `this` value as the argument.
2. ReturnIfAbrupt(`O`).
3. Let `lenValue` be the result of Get(`O`, "length").
4. Let `len` be ToLength(`lenValue`).
5. ReturnIfAbrupt(`len`).
6. If `IsCallable(callbackfn)` is false, throw a `TypeError` exception.
7. Let `thisArg` be `undefined`; else let `T` be `undefined`.
8. Let `C` be the result of Get(`O`, "constructor").
9. ReturnIfAbrupt(`C`).
10. If `IsConstructor(C)` is false, then
    a. Throw a `TypeError` exception.
11. Let `kept` be a new empty List.
12. Let `k` be 0.
13. Let `captured` be 0.
14. Repeat, while `k < len`
    a. Let `Pk` be `ToString(k)`.
    b. Let `kValue` be the result of Get(`O`, `Pk`).
    c. ReturnIfAbrupt(`kValue`).
    d. Let `selected` be the result of calling the `[[Call]]` internal method of `callbackfn` with `T` as thisArgument and a List containing `kValue`, `k`, and `O` as argumentsList.
    e. ReturnIfAbrupt(`selected`).
    f. If `ToBoolean(selected)` is true, then
        i. Append `kValue` to the end of `kept`.
        ii. Increase `captured` by 1.
    g. Increase `k` by 1.
15. Let `A` be the result of `OrdinaryConstruct(C, (captured))`.
16. Let `n` be 0.
17. For each element `e` of `kept`
    a. Let `status` be the result of `CreateOwnDataProperty(A, ToString(n), e)`.
    b. Assert: `status` is true.
    c. Increment `n` by 1.
18. Return `A`.

The length property of the `filter` method is 1.

22.2.3.10 `%TypedArray%.prototype.findIndex ( predicate, thisArg = undefined )`

 `%TypedArray%.prototype.findIndex` is a distinct function that implements the same algorithm as `Array.prototype.findIndex` as defined in 22.1.3.8. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.

The length property of the `find` method is 1.

22.2.3.11 `%TypedArray%.prototype.findIndex ( predicate, thisArg = undefined )`

 `%TypedArray%.prototype.findIndex` is a distinct function that implements the same algorithm as `Array.prototype.findIndex` as defined in 22.1.3.9. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.
The length property of the `findIndex` method is 1.

22.2.3.12 `%TypedArray%.prototype.forEach ( callbackfn, thisArg = undefined )`

`%TypedArray%.prototype.forEach` is a distinct function that implements the same algorithm as `Array.prototype.forEach` as defined in 22.1.3.10. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.

The length property of the `forEach` method is 1.

22.2.3.13 `%TypedArray%.prototype.indexOf ( searchElement, fromIndex = 0 )`

`%TypedArray%.prototype.indexOf` is a distinct function that implements the same algorithm as `Array.prototype.indexOf` as defined in 22.1.3.11. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.

The length property of the `indexOf` method is 1.

22.2.3.14 `%TypedArray%.prototype.keys ()`

The initial value of the `%TypedArray%.prototype.keys` data property is the same built-in function object as the `Array.prototype.keys` method defined in 22.1.3.13.

22.2.3.15 `%TypedArray%.prototype.lastIndexOf ( searchElement, fromIndex = this.length - 1 )`

`%TypedArray%.prototype.lastIndexOf` is a distinct function that implements the same algorithm as `Array.prototype.lastIndexOf` as defined in 22.1.3.14. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.

The length property of the `lastIndexOf` method is 1.

22.2.3.16 `%TypedArray%.prototype.map ( callbackfn, thisArg = undefined )`

The interpretation and use of the arguments of `%TypedArray%.prototype.map` are the same as for `Array.prototype.map` as defined in 22.1.3.15.

Commented [AWB13174]: `buffer` needs to be an accessor both to comply with WebIDL requirements and to support the Kronos neutering strawman requirements.
When the map method is called with one or two arguments, the following steps are taken:

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenValue be the result of Get(O, "length").
4. Let len be ToLength(lenValue).
5. ReturnIfAbrupt(len).
6. If IsCallable(callbackfn) is false, throw a TypeError exception.
7. If thisArg was supplied, let T be thisArg; else let T be undefined.
8. Let C be the result of Get(O, "constructor").
9. ReturnIfAbrupt(C).
10. If IsConstructor(C) is true, then
   a. Let A be the result of OrdinaryConstruct(C, ([len])).
11. Else,
   a. Throw a TypeError exception.
12. Let k be 0.
13. Repeat, while k < len
   a. Let Pk be ToString(k).
   b. Let kValue be the result of Get(O, Pk).
   c. ReturnIfAbrupt(kValue).
   d. Let mappedValue be the result of calling the [[Call]] internal method of callbackfn with T as thisArgument and a List containing kValue, k, and O as argumentsList.
   e. ReturnIfAbrupt(mappedValue).
   f. Let status be the result of Put(A, Pk, mappedValue, true).
   g. ReturnIfAbrupt(mappedValue).
   h. Increase k by 1.
14. Return A.

The length property of the map method is 1.

22.2.3.19 %TypedArray%.prototype.reduce ( callbackfn [, initialValue] )

%TypedArray%.prototype.reduce is a distinct function that implements the same algorithm as Array.prototype.reduce as defined in 22.1.3.18. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.

The length property of the reduce method is 1.

22.2.3.20 %TypedArray%.prototype.reduceRight ( callbackfn [, initialValue] )

%TypedArray%.prototype.reduceRight is a distinct function that implements the same algorithm as Array.prototype.reduceRight as defined in 22.1.3.19. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.

The length property of the reduceRight method is 1.

22.2.3.21 %TypedArray%.prototype.reverse ()

%TypedArray%.prototype.reverse is a distinct function that implements the same algorithm as Array.prototype.reverse as defined in 22.1.3.20. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.

22.2.3.22 %TypedArray%.prototype.set(array, offset = 0)

Set multiple values in this TypedArray, reading the values from the object array. The optional offset value indicates the first element index in this TypedArray where values are written. If omitted, it is assumed to be 0.
1. Assert: typedArray does not have a [[ViewedArrayBuffer]] internal data property. If it does, the definition in 22.2.3.23 applies.
2. Let target be the result of calling ToObject with the this value as its argument.
3. ReturnIfAbrupt(target).
4. If target does not have a [[ViewedArrayBuffer]] internal data property throw a TypeError exception.
5. Let targetBuffer be the value of target’s [[ViewedArrayBuffer]] internal data property.
6. If targetBuffer is undefined, then throw a TypeError exception.
7. Let targetLength be the value of target’s [[ArrayLength]] internal data property.
8. Let targetOffset be ToInteger (offset)
9. ReturnIfAbrupt(targetOffset).
10. If targetOffset < 0, then throw a RangeError exception.
11. Let targetName be the string value target’s [[TypedArrayName]] internal data property.
12. Let targetElementSize be the Number value of the Element Size value specified in for targetName.
13. Let targetType be the string value of the Element Type value in for targetName.
14. Let targetByteArrayOffset be the value of target’s [[ByteOffset]] internal data property.
15. Let src be the result of ToObject(array).
16. ReturnIfAbrupt(src).
17. Let srcLen be the result of Get(src, "length").
18. Let numberLength be ToNumber(srcLen).
19. Let srcLength be ToInteger(numberLength).
20. ReturnIfAbrupt(srcLength).
21. If numberLength ≠ srcLength or srcLength < 0, then throw a TypeError exception.
22. If srcLength + targetOffset > targetLength, then throw a RangeError exception.
23. Let targetByteIndex be targetOffset * targetElementSize + targetByteArrayOffset.
24. Let k be 0.
25. Let limit be targetByteIndex + targetElementSize * min(srcLength, targetLength – targetOffset).
26. Repeat, while targetByteIndex < limit
   a. Let kValue be ToInteger (k).
   b. Let k be ToNumber(kValue).
   c. Perform SetValueInBuffer(targetBuffer, targetByteIndex, targetType, kNumber).
   d. Set k to k + 1.
   e. Set targetByteIndex to targetByteIndex + targetElementSize.
27. Return undefined.

22.2.3.23 %TypedArray%.prototype.set(typedArray, offset = 0)

Set multiple values in this TypedArray, reading the values from the typedArray argument object. The optional offset value indicates the first element index in this TypedArray where values are written. If omitted, it is assumed to be 0.

1. Assert: typedArray has a [[ViewedArrayBuffer]] internal data property. If it does not, the definition in 22.2.3.22 applies.
2. Let target be the result of calling ToObject with the this value as its argument.
3. ReturnIfAbrupt(target).
4. If target does not have a [[ViewedArrayBuffer]] internal data property throw a TypeError exception.
5. Let targetBuffer be the value of target’s [[ViewedArrayBuffer]] internal data property.
6. If targetBuffer is undefined, then throw a TypeError exception.
7. Let targetLength be the value of target’s [[ArrayLength]] internal data property.
8. Let targetOffset be ToInteger (offset)
9. ReturnIfAbrupt(targetOffset).
10. If targetOffset < 0, then throw a RangeError exception.
11. Let targetName be the string value target’s [[TypedArrayName]] internal data property.
12. Let targetType be the string value of the Element Type value in Table 36 for targetName.
13. Let targetElementSize be the Number value of the Element Size value specified in Table 36 for targetName.
14. Let targetByteArrayOffset be the value of target’s [[ByteOffset]] internal data property.
15. Let srcBuffer be the value of typedArray’s [[ViewedArrayBuffer]] internal data property.
16. If srcBuffer is undefined, then throw a TypeError exception.
17. Let srcName be the string value typedArray’s [[TypedArrayName]] internal data property.
18. Let srcType be the string value of the Element Type value in Table 36 for srcName.
19. Let srcElementSize be the Number value of the Element Size value specified in Table 36 for srcName.
20. Let srcLength be the value of typedArray's [[ArrayLength]] internal data property.
21. Let srcByteOffset be the value of typedArray's [[ByteOffset]] internal data property.
22. If srcLength + targetOffset > targetLength, then throw a RangeError exception.
23. If SameValue(srcBuffer, targetBuffer) is true, then
   a. Let srcBuffer be the result of calling CloneArrayBuffer(srcBuffer, srcByteOffset, srcType, srcLength).
   b. Let srcByteIndex be 0.
24. Else, let srcByteIndex be srcByteOffset.
25. Let targetByteIndex be targetOffset × targetElementSize + targetByteOffset.
26. Let limit be targetByteIndex + targetElementSize × min(srcLength, targetLength − targetOffset).
27. Repeat, while targetByteIndex < limit
   a. Let value be the result of GetValueFromBuffer (srcBuffer, srcByteIndex, srcType).
   b. Let status be the result of SetValueInBuffer (targetBuffer, targetByteIndex, targetType, value).
   c. Set srcByteIndex to srcByteIndex + srcElementSize.
   d. Set targetByteIndex to targetByteIndex + targetElementSize.

22.2.3.24 %TypedArray%.prototype.slice ( start, end )

The interpretation and use of the arguments of %TypedArray%.prototype.slice are the same as for Array.prototype.slice as defined in 22.1.3.22. The following steps are taken:

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Let lenVal be the result of Get(O, "length").
4. Let len be ToLength(lenVal).
5. ReturnIfAbrupt(len).
6. Let relativeStart be ToInteger(start).
7. ReturnIfAbrupt(relativeStart).
8. If relativeStart is negative, let k be max((len + relativeStart),0); else let k be min(relativeStart, len).
9. If end is undefined, let relativeEnd be len; else let relativeEnd be ToInteger(end).
10. ReturnIfAbrupt(relativeEnd).
11. If relativeEnd is negative, let final be max((len + relativeEnd),0); else let final be min(relativeEnd, len).
12. Let count be final − k.
13. Let C be the result of Get(O, "constructor").
14. ReturnIfAbrupt(C).
15. If IsConstructor(C) is true, then
   a. Let A be the result of OrdinaryConstruct(C, (count)).
16. Else,
   a. Throw a TypeError exception.
17. Let n be 0.
18. Repeat, while k < final
   a. Let Pk be ToString(k).
   b. Let Value be the result of Get(O, Pk).
   c. ReturnIfAbrupt(Value).
   d. Let status be the result of Put(A, ToString(n), kValue, true).
   e. ReturnIfAbrupt(status).
   f. If status is false, throw a TypeError exception.
   g. Increase k by 1.
   h. Increase n by 1.
19. Return A.

The length property of the slice method is 2.
22.2.3.25 %TypedArray%.prototype.some (callbackfn, thisArg = undefined)

%TypedArray%.prototype.some is a distinct function that implements the same algorithm as Array.prototype.some as defined in 22.1.3.23. However, the implementation of the algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse.

The length property of the some method is 1.

22.2.3.26 %TypedArray%.prototype.sort (comparefn)

%TypedArray%.prototype.sort is a distinct function that implements the same requirements as those of Array.prototype.sort as defined in 22.1.3.24. However, the implementation of the %TypedArray%.prototype.sort algorithm may be optimized to assume that the this value is an object that has a fixed length and whose integer indexed properties are not sparse. The only internal methods of the this object call that the algorithm may use are [[Get]] and [[Set]].

The following version of SortCompare is used by %TypedArray%.prototype.sort. It performs a numeric coparison rather than the string comparision used in 22.1.3.24.

The Typed Array SortCompare abstract operation is called with two arguments $j$ and $k$, the following steps are taken:

1. Let $jString$ be ToString($j$).
2. Let $kString$ be ToString($k$).
3. Let $x$ be the result of Get(obj, $jString$).
4. ReturnIfAbrupt($x$).
5. Let $y$ be the result of Get(obj, $kString$).
6. ReturnIfAbrupt($y$).
7. Assert: Both Type($x$) and Type($y$) is Number.
8. If $x$ and $y$ are both NaN, return $+0$.
9. If $x$ is NaN, return $1$.
10. If $y$ is NaN, return $-1$.
11. If the argument comparefn is not undefined, then
   a. If IsCallable(comparefn) is false, throw a TypeError exception.
   b. Return the result of calling the [[Call]] internal method of comparefn passing undefined as thisArgument and with a List containing the values of $x$ and $y$ as the argumentsList.
12. If $x < yStrin$, return $-1$.
13. If $x > y$, return $1$.
14. Return $+0$.

NOTE 1 Because NaN always compares greater than any other value, NaN property values always sort to the end of the result.

22.2.3.27 %TypedArray%.prototype.subarray(begin = 0, end = this.length)

Returns a new TypedArray object whose element types is the same as this TypedArray and whose ArrayBuffer is the same as the ArrayBuffer of this TypedArray, referencing the elements at begin, inclusive, up to end, exclusive. If either begin or end is negative, it refers to an index from the end of the array, as opposed to from the beginning.

1. Let O be the result of calling ToObject with the this value as its argument.
2. ReturnIfAbrupt(O).
3. If O does not have a [[ViewedArrayBuffer]] internal data property throw a TypeError exception.
4. Let buffer be the value of O’s [[ViewedArrayBuffer]] internal data property.
5. If buffer is undefined, then throw a TypeError exception.
6. Let srcLength be the value of O’s [[ArrayLength]] internal data property.
7. Let beginInt be ToInteger(begin)
8. ReturnIfAbrupt(beginInt).
9. If beginInt < 0, then let beginInt be srcLength + beginInt.
10. Let beginIndex be min(srcLength, max(0, beginInt)).
11. If end is undefined, then let end be srcLength.
12. Let endIndex be ToInteger(end).
13. If endInt < 0, then let endInt be srcLength + endInt.
14. If endIndex < beginIndex, then let endIndex be beginIndex.
15. Let newLength be endIndex - beginIndex.
16. Let constructorName be the string value O's [[TypedArrayName]] internal data property.
17. Let elementType be the string value of the Element Type value in constructorName.
18. Let elementSize be the Number value of the Element Size value specified in constructorName.
19. Let constructor be the result of Get(O, "constructor").
20. If IsConstructor(constructor) is false, then throw a TypeError exception.
21. Let argumentsList be a List consisting of buffer, beginByteOffset, and newLength.
22. Return the result of calling the [[Construct]] internal method of constructor with argumentsList as the argument.

22.2.3.28 %TypedArray%.prototype.toLocaleString ( )
The initial value of the %TypedArray%.prototype.toLocaleString data property is the same built-in function object as the Array.prototype.toLocaleString method defined in 22.1.3.26.

22.2.3.29 %TypedArray%.prototype.toString ( )
The initial value of the %TypedArray%.prototype.toString data property is the same built-in function object as the Array.prototype.toString method defined in 22.1.3.27.

22.2.3.30 %TypedArray%.prototype.values ( )
The initial value of the %TypedArray%.prototype.values data property is the same built-in function object as the Array.prototype.values method defined in 22.1.3.29.

22.2.3.31 %TypedArray%.prototype[ @@iterator ] ( )
The initial value of the @@iterator property is the same function object as the initial value of the %TypedArray%.prototype.values property.

22.2.3.32 get %TypedArray%.prototype[ @@toStringTag ]
%TypedArray%.prototype[ @@toStringTag ] is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:
1. Let O be the result of calling ToObject with the this value as its argument.
2. ReturnIfAbrupt(O).
3. If O does not have a [[TypedArrayName]] internal data property throw a TypeError exception.
4. Let name be the value of O's [[TypedArrayName]] internal data property.
5. Assert: name is a String value.
6. Return name.

This property has the attributes { [[Enumerable]]: false, [[Configurable]]: true }.

22.2.4 The TypedArray Constructors
Each of these TypedArray constructor objects has the structure described below, differing only in the name used as the constructor name instead of %TypedArray%, in Table 36.
When a `TypedArray` constructor is called as a function rather than as a constructor, it initialises a new `TypedArray` object. The `this` value passed in the call must be an Object with an `[[ViewedArrayBuffer]]` internal data property whose value is `undefined`. The constructor function initialises the `this` value using the argument values.

The `TypedArray` constructors are designed to be subclassable. They may be used as the value of an `extends` clause of a class declaration. Subclass constructors that intended to inherit the specified `TypedArray` behaviour must include a `super` call to the `TypedArray` constructor to initialise subclass instances.

### 22.2.4.1 new `TypedArray`( ... `argumentsList`)

A `TypedArray` constructor with a list of arguments `argumentsList` performs the following steps:

1. Let `F` be the `TypedArray` function object that was called.
2. Let `realmF` be `F`'s `[[Realm]]` internal data property.
3. Let `super` be `realmF`'s intrinsic object named `%TypedArray%`.
4. Let `argumentsList` be the `argumentsList` argument of the `[[Call]]` internal method that invoked `F`.
5. Return the result of calling the `[[Call]]` internal method of `super` with `F` and `argumentsList` as arguments.

### 22.2.4.2 new `TypedArray`( ... `argumentsList`)

A `TypedArray` constructor called as part of a new expression performs the following steps:

1. Let `F` be the `TypedArray` function object on which the `new` operator was applied.
2. Let `argumentsList` be the `argumentsList` argument of the `[[Construct]]` internal method that was invoked by the `new` operator.
3. Return the result of `OrdinaryConstruct(F, argumentsList)`.

### 22.2.5 Properties of the `TypedArray` Constructors

The value of the `[[Prototype]]` internal data property of each `TypedArray` constructor is the `%TypedArray%` intrinsic object (22.2.1).

Each `TypedArray` constructor has a `[[TypedArrayConstructor]]` internal data property whose String value is the constructor name in the corresponding row in Table 36.

Besides a `length` property (whose value is 3), each `TypedArray` constructor has the following properties:

#### 22.2.5.1 `TypedArray.BYTES_PER_ELEMENT`

The value of `TypedArray.BYTES_PER_ELEMENT` is the Number value of the Element Size value specified in `for TypedArray`.

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

#### 22.2.5.2 `TypedArray.prototype`

The initial value of `TypedArray.prototype` is the corresponding `TypedArray` prototype object (22.2.6).

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

### 22.2.6 Properties of `TypedArray` Prototype Objects

The value of the `[[Prototype]]` internal data property of a `TypedArray` prototype object is the standard built-in `%TypedArrayPrototype%` object (22.2.3). A `TypedArray` prototype object is an ordinary object. It does not have a `[[ViewedArrayBuffer]]` or any other of the internal data properties that are specific to `TypedArray` instance objects.
22.2.6.1 TypedArray.prototype.BYTES_PER_ELEMENT

The value of TypedArray.prototype.BYTES_PER_ELEMENT is the Number value of the Element Size value specified in for TypedArray.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

22.2.6.2 TypedArray.prototype.constructor

The initial value of a TypedArray.prototype.constructor is the corresponding standard built-in TypedArray constructor.

22.2.7 Properties of TypedArray Instances

TypedArray instances are Integer Indexed exotic objects. Each TypedArray instances inherits properties from the corresponding TypedArray prototype object. Each TypedArray instances have the following internal data properties: [[ViewedArrayBuffer]], [[TypedArrayName]], [[ByteLength]], [[ByteOffset]], and [[ArrayLength]].

23 Keyed Collection

23.1 Map Objects

Map objects are collections of key/value pairs where both the keys and values may be arbitrary ECMAScript language values. A distinct key value may only occur in one key/value pair within the Map’s collection. Distinct key values as discriminated using the a comparison algorithm that is selected when the Map is created.

A Map object can iterate its elements in insertion order. Map object must be implemented using either hash tables or other mechanisms that, on average, provide access times that are sublinear on the number of elements in the collection. The data structures used in this Map objects specification is only intended to describe the required observable semantics of Map objects. It is not intended to be a viable implementation model.

23.1.1 The Map Constructor

The Map constructor is the %Map% intrinsic object and the initial value of the Map property of the global object. When Map is called as a function rather than as a constructor, it initialises its this value with the internal state necessary to support the Map.prototype internal methods.

The Map constructor is designed to be subclassable. It may be used as the value in an extends clause of a class definition. Subclass constructors that intend to inherit the specified Map behaviour must include a super call to Map.

23.1.1.1 Map (iterable = undefined , comparator = undefined )

When the Map function is called with optional arguments iterable and comparator the following steps are taken:

1. Let map be the this value.
2. If Type(map) is not Object then, throw a TypeError exception.
3. If map does not have a [[MapData]] internal data property, then throw a TypeError exception.
4. If map’s [[MapData]] internal data property is not undefined, then throw a TypeError exception.
5. If iterable is not present, let iterable be undefined.
6. If iterable is either undefined or null, then let iter be undefined.
7. Else,
   a. Let iter be the result of GetIterator(iterable).
   b. ReturnIfAbrupt(iter).
   c. Let adder be the result of Get(map, “set”).
   d. ReturnIfAbrupt(adder).
   e. If IsCallable(adder) is false, throw a TypeError Exception.
8. If comparator is not undefined, then
   a. If comparator is not "is", then throw a RangeError Exception.
9. Set map’s [[MapData]] internal data property to a new empty List.
10. Set map’s [[MapComparator]] internal data property to comparator.
11. If iter is undefined, then return map.
12. Repeat
   a. Let next be the result of IteratorNext(iter).
   b. ReturnIfAbrupt(next).
   c. Let done be IteratorComplete(next).
   d. ReturnIfAbrupt(done).
   e. If done is true, then return NormalCompletion(map).
   f. Let nextItem be IteratorValue(next).
   g. ReturnIfAbrupt(nextItem).
   h. If Type(nextItem) is not Object, then throw a TypeError execution.
   i. Let k be the result of Get(nextItem, "0").
   j. ReturnIfAbrupt(k).
   k. Let v be the result of Get(nextItem, "1").
   l. ReturnIfAbrupt(v).
   m. Let status be the result of calling the [[Call]] internal method of adder with map as thisArgument and a List whose elements are k and v as argumentsList.
   n. ReturnIfAbrupt(status).

NOTE If the parameter iterable is present, it is expected to be an object that implements either an @@iterator method that returns an iterator object that produces two element array-like objects whose first element is a value that will be used as a Map key and whose second element is the value to associate with that key.

23.1.1.2 new Map ( ... argumentsList )

When Map is called as part of a new expression it is a constructor: it initialises a newly created object.

Map called as part of a new expression with argument list argumentsList performs the following steps:

1. Let F be the Map function object on which the new operator was applied.
2. Let argumentsList be the argumentsList argument of the [[Construct]] internal method that was invoked by the new operator.
3. Return the result of OrdinaryConstruct(F, argumentsList).

If Map is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.

23.1.2 Properties of the Map Constructor

The value of the [[Prototype]] internal data property of the Map constructor is the Function prototype object (19.2.3).

Besides the length property (whose value is 0), the Map constructor has the following property:

23.1.2.1 Map.prototype

The initial value of Map.prototype is the Map prototype object (23.1.3).

This property has the attributes { [Writable]: false, [Enumerable]: false, [Configurable]: false }.

23.1.2.2 Map[ @@create ] ()

The @@create method of a Map function object F performs the following steps:

1. Let F be the this value.
2. Let `obj` be the result of calling `OrdinaryCreateFromConstructor(F, "MapPrototype", [MapData], [MapComparator]).
3. Return `obj`.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

23.1.3 Properties of the Map Prototype Object

The value of the [[Prototype]] internal data property of the Map prototype object is the standard built-in Object prototype object (19.1.4). The Map prototype object is an ordinary object. It does not have a [[MapData]] or a [[MapComparator]] internal data property.

23.1.3.1 Map.prototype.clear()

The following steps are taken:

1. Let `M` be the this value.
2. If `Type(M)` is not Object, then throw a TypeError exception.
3. If `M` does not have a [[MapData]] internal data property throw a TypeError exception.
4. If `M`’s [[MapData]] internal data property is undefined, then throw a TypeError exception.
5. Let `entries` be the List that is the value of `M`’s [[MapData]] internal data property.
6. Repeat for each Record `[[key]], [[value]]` `p` that is an element of `entries`:
   a. Set `p. [[key]]` to empty.
   b. Set `p. [[value]]` to empty.
7. Return undefined.

23.1.3.2 Map.prototype.constructor

The initial value of Map.prototype.constructor is the built-in Map constructor.

23.1.3.3 Map.prototype.delete(key)

The following steps are taken:

1. Let `M` be the this value.
2. If `Type(M)` is not Object, then throw a TypeError exception.
3. If `M` does not have a [[MapData]] internal data property throw a TypeError exception.
4. If `M`’s [[MapData]] internal data property is undefined, then throw a TypeError exception.
5. If `M`’s [[MapComparator]] internal data property is undefined, then let `same` be the abstract operation SameValueZero.
6. Else, let `same` be the abstract operation SameValue.
7. Let `entries` be the List that is the value of `M`’s [[MapData]] internal data property.
8. Repeat for each Record `[[key]], [[value]]` `p` that is an element of `entries`:
   a. If `same([[key]], key)`, then
      i. Set `p. [[key]]` to empty.
      ii. Set `p. [[value]]` to empty.
      iii. Return true.
9. Return false.

NOTE The value empty is used as a specification device to indicate that an entry has been deleted. Actual implementations may take other actions such as physically removing the entry from internal data structures.

23.1.3.4 Map.prototype.entries()

The following steps are taken:

1. Let `M` be the this value.
2. If `Type(M)` is not Object, then throw a TypeError exception.
3. Return the result of calling the CreateMapIterator abstract operation with arguments `M` and "key+value".

Commented [AWB14181]: Need to move after delete
23.1.3.5 Map.prototype.forEach (callbackfn, thisArg = undefined)

callbackfn should be a function that accepts three arguments. forEach calls callbackfn once for each key/value pair present in the map object, in key insertion order. callbackfn is called only for keys of the map which actually exist; it is not called for keys that have been deleted from the map.

If a thisArg parameter is provided, it will be used as the this value for each invocation of callbackfn. If it is not provided, undefined is used instead.

NOTE If callbackfn is an Arrow Function, this was lexically bound when the function was created so thisArg will have no effect.

callbackfn is called with three arguments: the value of the item, the key of the item, and the Map object being traversed.

forEach does not directly mutate the object on which it is called but the object may be mutated by the calls to callbackfn.

NOTE Each key is visited only once with the value that is current at the time of the visit. If the value associated with a key is modified after it has been visited, it is not re-visited. Keys that are deleted after the call to forEach begins and before being visited are not visited. New keys added, after the call to forEach begins are visited.

When the forEach method is called with one or two arguments, the following steps are taken:

1. Let M be the this value.
2. If Type(M) is not Object, then throw a TypeError exception.
3. If M does not have a [[MapData]] internal data property throw a TypeError exception.
4. If M’s [[MapData]] internal data property is undefined, then throw a TypeError exception.
5. If IsCallable(callbackfn) is false, throw a TypeError exception.
6. If thisArg was supplied, let T be thisArg; else let T be undefined.
7. Let entries be the List that is the value of M’s [[MapData]] internal data property.
8. Repeat for each Record {[[key]], [[value]]} e that is an element of entries, in original key insertion order
   a. If e.[[key]] is not empty, then
      i. Let funcResult be the result of calling the [[Call]] internal method of callbackfn with T as thisArgument and a List containing e.[[value]], e.[[key]], and M as argumentsList.
      ii. ReturnIfAbrupt(funcResult).
9. Return undefined.

The length property of the forEach method is 1.

23.1.3.6 Map.prototype.get (key)

The following steps are taken:

1. Let M be the this value.
2. If Type(M) is not Object, then throw a TypeError exception.
3. If M does not have a [[MapData]] internal data property throw a TypeError exception.
4. If M’s [[MapData]] internal data property is undefined, then throw a TypeError exception.
5. Let entries be the last that is the value of M’s [[MapData]] internal data property.
6. If M’s [[MapComparator]] internal data property is undefined, then let same be the abstract operation SameValueZero.
7. Else, let same be the abstract operation SameValue.
8. Repeat for each Record {[[key]], [[value]]} p that is an element of entries,
   a. If samep.[[key]], key, then return p.[[value]]
9. Return undefined.

23.1.3.7 Map.prototype.has (key)

The following steps are taken:

© Ecma International 2013
1. Let M be the this value.
2. If Type(M) is not object, then throw a TypeError exception.
3. If M does not have a [[MapData]] internal data property throw a TypeError exception.
4. If M's [[MapData]] internal data property is undefined, then throw a TypeError exception.
5. Let entries be the List that is the value of M's [[MapData]] internal data property.
6. If M's [[MapComparator]] internal data property is undefined, then let same be the abstract operation SameValueZero.
7. Else, let same be the abstract operation SameValue.
8. Repeat for each Record {
   a. If same(key, p.key), then return true.
9. Return false.

23.1.3.8 Map.prototype.keys ()
The following steps are taken:
1. Let M be the this value.
2. If Type(M) is not Object, then throw a TypeError exception.
3. Return the result of calling the CreateMapIterator abstract operation with arguments M and "key".

23.1.3.9 Map.prototype.set (key, value)
The following steps are taken:
1. Let M be the this value.
2. If Type(M) is not Object, then throw a TypeError exception.
3. If M does not have a [[MapData]] internal data property throw a TypeError exception.
4. If M's [[MapData]] internal data property is undefined, then throw a TypeError exception.
5. Let entries be the List that is the value of M's [[MapData]] internal data property.
6. If M's [[MapComparator]] internal data property is undefined, then let same be the abstract operation SameValueZero.
7. Else, let same be the abstract operation SameValue.
8. Repeat for each Record {
   a. If same(key, p.key), then
      i. Set p.value to value.
   ii. Return M.
9. Let p be the Record {
   10. Append p as the last element of entries.
11. Return M.

23.1.3.10 get Map.prototype.size
Map.prototype.size is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:
1. Let M be the this value.
2. If Type(M) is not Object, then throw a TypeError exception.
3. If M does not have a [[MapData]] internal data property throw a TypeError exception.
4. If M's [[MapData]] internal data property is undefined, then throw a TypeError exception.
5. Let entries be the List that is the value of M's [[MapData]] internal data property.
6. Let count be 0.
7. For each Record {
   a. If p.value is not empty then
      i. Set count to count+1.
8. Return count.

23.1.3.11 Map.prototype.values ()
The following steps are taken:
1. Let M be the this value.
2. If Type(M) is not Object, then throw a TypeError exception.
3. Return the result of calling the CreateMapIterator abstract operation with arguments M and "value".

23.1.3.12 Map.prototype[@@iterator]( )

The initial value of the @@iterator property is the same function object as the initial value of the entries property.

23.1.3.13 Map.prototype[@@toStringTag]

The initial value of the @@toStringTag property is the string value "Map".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

23.1.4 Properties of Map Instances

Map instances are ordinary objects that inherit properties from the Map prototype. Map instances also have a [[MapData]] internal data property and a [[MapComparator]] internal data property.

23.1.5 Map Iterator Object Structure

A Map iterator is an object, with the structure defined below, that represents a specific iteration over some specific Map instance object. There is not a named constructor for Map iterator objects. Instead, map iterator objects are created by calling certain methods of Map instance objects.

23.1.5.1 CreateMapIterator Abstract Operation

Several methods of Map objects return Iterator objects. The abstract operation CreateMapIterator with arguments map and kind is used to create such iterator objects. It performs the following steps:

1. Let M be the result of calling ToObject(map).
2. ReturnIfAbrupt(M).
3. If M does not have a [[MapData]] internal data property throw a TypeError exception.
4. Let entries be the List that is the value of M's [[MapData]] internal data property.
5. Let iterator be the result of ObjectCreate(%MapIteratorPrototype%,  ([[Map]], [[MapNextIndex]],
       [[MapIterationKind]])).
6. Set iterator's [[Map]] internal data property to M.
7. Set iterator's [[MapNextIndex]] internal data property to 0.
8. Set iterator's [[MapIterationKind]] internal data property to kind.
9. Return iterator.

23.1.5.2 The Map Iterator Prototype

All Map Iterator Objects inherit properties from a common Map Iterator Prototype object. The [[Prototype]] internal data property of the Map Iterator Prototype is the %ObjectPrototype% intrinsic object. In addition, the Map Iterator Prototype has the following properties:

23.1.5.2.1 MapIterator.prototype.constructor

23.1.5.2.2 MapIterator.prototype.next( )

1. Let O be the this value.
2. If Type(O) is not Object, throw a TypeError exception.
3. If O does not have all of the internal properties of a Map Iterator Instance (23.1.5.3), throw a TypeError exception.
4. Let m be the value of the [[Map]] internal data property of O.
5. Let index be the value of the [[MapNextIndex]] internal data property of O.
6. Let itemKind be the value of the [[MapIterationKind]] internal data property of O.

Commented [AWB10182]: This is how we identify a property whose key is a built-in Symbol
Commented [AWB10183]: Do we really want to do this sort of method sharing. It has a bad smell.
Commented [AWB10184]: TODO: need to decide what to use for a constructor for these sort of objects. Probably we should try to consistently follow the "class model" wherever we can.
7. Assert: \( m \) has a \([[\text{MapData}] \text{ internal data property}] \) and \( m \) has been initialised so the value of \([[\text{MapData}] \text{ is not undefined}] \).
8. Let \( \text{entries} \) be the List that is the value of the \([[\text{MapData}] \text{ internal data property}] \) of \( m \).
9. Repeat while \( \text{index} \) is less than the total number of elements of \( \text{entries} \). The number of elements must be redetermined each time this method is evaluated.
   a. Let \( e \) be the Record \([[\text{key}],[\text{value}]\text{ at } 0-\text{origined insertion position } \text{index} \text{ of } \text{entries} \].
   b. Set \( \text{index} \) to \( \text{index} + 1 \);
   c. Set the \([[\text{MapNextIndex}] \text{ internal data property}] \) of \( O \) to \( \text{index} \).
   d. If \( e[\text{key}] \) is not empty, then
      i. If \( \text{itemKind} \) is "key" then, let \( \text{result} \) be \( e[\text{key}] \).
      ii. Else if \( \text{itemKind} \) is "value" then, let \( \text{result} \) be \( e[\text{value}] \).
      iii. Else,
         1. Assert: \( \text{itemKind} \) is "key+value".
         2. Let \( \text{result} \) be the result of the abstract operation \( \text{ArrayCreate} \) with argument 2.
         3. Assert: \( \text{result} \) is a new, well-formed Array object so the following operations will never fail.
         4. Call \( \text{CreateOwnDataProperty(result, } 0, e[\text{key}] \text{)} \).
         5. Call \( \text{CreateOwnDataProperty(result, } 1, e[\text{value}] \text{)} \).
      iv. Return \( \text{CreateItrResultObject(result, false)} \).
10. Return \( \text{CreateItrResultObject(undefined, true)} \).

23.1.5.2.3 \( \text{MapIterator.prototype [ @@iterator ] ( )} \)

The following steps are taken:
1. Return the \( \text{this} \) value.

23.1.5.2.4 \( \text{MapIterator.prototype [ @@toStringTag ]} \)

The initial value of the \( \text{@@toStringTag} \) property is the string value "Map Iterator".

23.1.5.3 Properties of Map Iterator Instances

Map iterator instances are ordinary objects that inherit properties from the Map iterator prototype (the intrinsic, \%MapIteratorPrototype\%). Map iterator instances are initially created with the internal properties described in Table 37.

Table 37 — Internal Data Properties of Map Iterator Instances

<table>
<thead>
<tr>
<th>Internal Data Property Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>([\text{Map}])</td>
<td>The Map object that is being iterated.</td>
</tr>
<tr>
<td>([\text{MapNextIndex}])</td>
<td>The integer index of the next Map data element to be examined by this iteration.</td>
</tr>
<tr>
<td>([\text{MapIterationKind}])</td>
<td>A string value that identifies what is to be returned for each element of the iteration. The possible values are: &quot;key&quot;, &quot;value&quot;, &quot;key+value&quot;.</td>
</tr>
</tbody>
</table>

23.2 Set Objects

Set objects are collections of ECMAScript language values. A distinct value may only occur once as an element of a Set's collection. Distinct values are discriminated using a comparision algorithm that is selected when the Set is created.
A Set object can iterate its elements in insertion order. Set objects must be implemented using either hash tables or other mechanisms that, on average, provide access times that are sublinear on the number of elements in the collection. The data structures used in this Set objects specification is only intended to describe the required observable semantics of Set objects. It is not intended to be a viable implementation model.

23.2.1 The Set Constructor

The Set constructor is the %Set% intrinsic object and the initial value of the Set property of the global object. When Set is called as a function rather than as a constructor, it initialises its this value with the internal state necessary to support the Set.prototype internal methods.

The Set constructor is designed to be subclassable. It may be used as the value in an extends clause of a class definition. Subclass constructors that intend to inherit the specified Set behaviour must include a super call to Set.

23.2.1.1 Set (iterable = undefined, comparator = undefined)

When the Set function is called with optional arguments iterable and comparator the following steps are taken:

1. Let set be the this value.
2. If Type(set) is not Object then, throw a TypeError exception.
3. If set does not have a [[SetData]] internal data property, then throw a TypeError exception.
4. If set's [[SetData]] internal data property is not undefined, then throw a TypeError exception.
5. If iterable is not present, let iterable be undefined.
6. If iterable is either undefined or null, then let iter be undefined.
7. Else,
   a. Let iter be the result of GetIterator(iterable).
   b. ReturnIfAbrupt(iter).
   c. Let adder be the result of Get(set, "add").
   d. ReturnIfAbrupt(adder).
   e. If IsCallable(adder) is false, throw a TypeError Exception.
8. If comparator is not present, let comparator be undefined.
9. If comparator is not undefined, then
   a. If comparator is not "is", then throw a RangeError Exception.
10. Set set's [[SetData]] internal data property to a new empty List.
11. Set set's [[SetComparator]] internal data property to comparator.
12. If iter is undefined, then return set.
13. Repeat
    a. Let next be the result of IteratorNext(iter).
    b. ReturnIfAbrupt(next).
    c. Let done be IteratorComplete(next).
    d. ReturnIfAbrupt(done).
    e. If done is true, then return set.
    f. Let nextValue be IteratorValue(next).
    g. ReturnIfAbrupt(nextValue).
    h. Let status be the result of calling the [[Call]] internal method of adder with set as thisArgument and a List whose sole element is nextValue as argumentsList.
    i. ReturnIfAbrupt(status).

23.2.1.2 new Set ( ... argumentsList)

When Set is called as part of a new expression it is a constructor: it initialises a newly created object.

Set called as part of a new expression with argument list argumentsList performs the following steps:

1. Let F be the Set function object on which the new operator was applied.
2. Let argumentsList be the argumentsList argument of the [[Construct]] internal method that was invoked by the new operator.
3. Return the result of OrdinaryConstruct(F, argumentsList).

If Set is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.

### 23.2.2 Properties of the Set Constructor

The value of the [[Prototype]] internal data property of the Set constructor is the Function prototype object (19.2.3).

Besides the length property (whose value is 0), the Set constructor has the following property:

#### 23.2.2.1 Set.prototype

The initial value of Set.prototype is the intrinsic %SetPrototype% object (23.2.3).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

#### 23.2.2.2 Set @@create ()

The @@create method of a Set function object F performs the following steps:

1. Let F be the this value.
2. Let obj be the result of calling OrdinaryCreateFromConstructor(F, "%SetPrototype", ([[SetData]], [[SetComparator]]).
3. Return obj.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

### 23.2.3 Properties of the Set Prototype Object

The value of the [[Prototype]] internal data property of the Set prototype object is the standard built-in Object prototype object (19.1.4). The Set prototype object is an ordinary object. It does not have a [[SetData]] or a [[SetComparator]] internal data property.

#### 23.2.3.1 Set.prototype.add (value )

The following steps are taken:

1. Let S be the this value.
2. If Type(S) is not Object, then throw a TypeError exception.
3. If S does not have a [[SetData]] internal data property throw a TypeError exception.
4. If S's [[SetData]] internal data property is undefined, then throw a TypeError exception.
5. Let entries be the List that is the value of S's [[SetData]] internal data property.
6. If S's [[SetComparator]] internal data property is undefined, then let same be the abstract operation SameValueZero.
7. Else, let same be the abstract operation SameValue.
8. Repeat for each e that is an element of entries, in original insertion order
   a. If e is not empty and same(e, value) is true, then
      i. Return S.
9. Append value as the last element of entries.
10. Return S.

#### 23.2.3.2 Set.prototype.clear ()

The following steps are taken:

Commented [AWB14186]: Because the @@create method is essential to the integrity of this "class" definition, just like the prototype property, it seems appropriate to freeze it in the same manner.
1. Let \( S \) be the \texttt{this} value.
2. If \( \text{Type}(S) \) is not Object, then throw a \texttt{TypeError} exception.
3. If \( S \) does not have a \([\text{SetData}]\) internal data property throw a \texttt{TypeError} exception.
4. If \( S \)'s \([\text{SetData}]\) internal data property is \texttt{undefined}, then throw a \texttt{TypeError} exception.
5. Let \( \text{entries} \) be the List that is the value of \( S \)'s \([\text{SetData}]\) internal data property.
6. Repeat for each \( e \) that is an element of \( \text{entries} \):
   a. Replace the element of \( \text{entries} \) whose value is \( e \) with an element whose value is \texttt{empty}.
7. Return \texttt{undefined}.

### 23.2.3.3 \texttt{Set.prototype.constructor}

The initial value of \texttt{Set.prototype.constructor} is the built-in \texttt{Set} constructor.

### 23.2.3.4 \texttt{Set.prototype.delete(value)}

The following steps are taken:

1. Let \( S \) be the \texttt{this} value.
2. If \( \text{Type}(S) \) is not Object, then throw a \texttt{TypeError} exception.
3. If \( S \) does not have a \([\text{SetData}]\) internal data property throw a \texttt{TypeError} exception.
4. If \( S \)'s \([\text{SetData}]\) internal data property is \texttt{undefined}, then throw a \texttt{TypeError} exception.
5. Let \( \text{entries} \) be the List that is the value of \( S \)'s \([\text{SetData}]\) internal data property.
6. Let \( \text{same} \) be the abstract operation \texttt{SameValueZero}.

7. Else, let \( \text{same} \) be the abstract operation \texttt{SameValue}.
8. Repeat for each \( e \) that is an element of \( \text{entries} \), in original insertion order:
   a. If \( e \) is not \texttt{empty} and \( \text{same}(e, \text{value}) \) is \texttt{true}, then
      i. Replace the element of \( \text{entries} \) whose value is \( e \) with an element whose value is \texttt{empty}.
      ii. Return \texttt{true}.
9. Return \texttt{false}.

**NOTE** The value \texttt{empty} is used as a specification device to indicate that an entry has been deleted. Actual implementations may take other actions such as physically removing the entry from internal data structures.

### 23.2.3.5 \texttt{Set.prototype.entries()} 

The following steps are taken:

1. Let \( S \) be the \texttt{this} value.
2. If \( \text{Type}(S) \) is not Object, then throw a \texttt{TypeError} exception.
3. Return the result of calling the \texttt{CreateSetIterator} abstract operation with arguments \( S \) and \"key\+value\".

**NOTE** For iteration purposes, a Set appears similar to a Map where each entry has the same value for its key and value.

### 23.2.3.6 \texttt{Set.prototype.forEach(callbackfn[, thisArg = undefined])}

\( \text{callbackfn} \) should be a function that accepts three arguments. \texttt{forEach} calls \( \text{callbackfn} \) once for each value present in the set object, in value insertion order. \( \text{callbackfn} \) is called only for values of the Set which actually exist; it is not called for keys that have been deleted from the set.

If a \texttt{thisArg} parameter is provided, it will be used as the \texttt{this} value for each invocation of \( \text{callbackfn} \). If it is not provided, \texttt{undefined} is used instead.

**NOTE** If \( \text{callbackfn} \) is an Arrow Function, this was lexically bound when the function was created so \texttt{thisArg} will have no effect.

\( \text{callbackfn} \) is called with three arguments: the first two arguments are a value contained in the Set. The same value of passed for both arguments. The Set object being traversed is passed as the third argument.
NOTE 2  The `callbackfn` is called with three arguments to be consistent with the call back functions used by `forEach` methods for `Map` and `Array`. For Sets, each item value is considered to be both the key and the value.

`forEach` does not directly mutate the object on which it is called but the object may be mutated by the calls to `callbackfn`.

NOTE 3  Each value is normally visited only once. However, a value will be revisited if it is deleted after it has been visited and then re-added before the to `forEach` call completes. Values that are deleted after the call to `forEach` begins and before being visited are not visited unless the value is added again before the to `forEach` call completes. New values added, after the call to `forEach` begins are visited.

When the `forEach` method is called with one or two arguments, the following steps are taken:

1. Let `S` be the this value.
2. If `Type(S)` is not Object, then throw a `TypeError` exception.
3. If `S` does not have a `[[SetData]]` internal data property throw a `TypeError` exception.
4. If `S`'s `[[SetData]]` internal data property is `undefined` then throw a `TypeError` exception.
5. If `IsCallable(callbackfn)` is `false` then throw a `TypeError` exception.
6. If `thisArg` was supplied, let `T` be `thisArg` else let `T` be `undefined`.
7. Let `entries` be the List that is the value of `S`'s `[[SetData]]` internal data property.
8. Repeat for each `e` that is an element of `entries`, in original insertion order
   a. If `e` is not empty, then
      i. Let `funcResult` be the result of calling the `[[Call]]` internal method of `callbackfn` with `T` as this argument and a List containing `e`, `e`, and `S` as argumentsList.
      ii. ReturnIfAbrupt(`funcResult`).
9. Return `undefined`.

The `length` property of the `forEach` method is 1.

23.2.3.7 Set.prototype.has ( value )

The following steps are taken:

1. Let `S` be the this value.
2. If `Type(S)` is not Object, then throw a `TypeError` exception.
3. If `S` does not have a `[[SetData]]` internal data property throw a `TypeError` exception.
4. If `S`'s `[[SetData]]` internal data property is `undefined` then throw a `TypeError` exception.
5. Let `entries` be the List that is the value of `S`'s `[[SetData]]` internal data property.
6. If `S`'s `[[SetComparator]]` internal data property is `undefined` then let `same` be the abstract operation `SameValueZero`.
7. Else, let `same` be the abstract operation `SameValue`.
8. Repeat for each `e` that is an element of `entries`,
   a. If `e` is not empty and `same(e, value)`, then return `true`.
9. Return `false`.

23.2.3.8 Set.prototype.keys ()

The initial value of the keys property is the same function object as the initial value of the values property.

NOTE  For iteration purposes, a Set appears similar to a Map where each entry has the same value for its key and value.

23.2.3.9 get Set.prototype.size

Set.prototype.size is an accessor property whose set accessor function is `undefined`. Its get accessor function performs the following steps:

1. Let `S` be the this value.
2. If `Type(S)` is not Object, then throw a `TypeError` exception.
3. If `S` does not have a `[[SetData]]` internal data property throw a `TypeError` exception.

Commented [AWB10187]: Do we really want to do this sort of method sharing.
4. If $S$’s [[SetData]] internal data property is undefined, then throw a TypeError exception.
5. Let entries be the List that is the value of $S$’s [[SetData]] internal data property.
6. Let count be 0.
7. For each $e$ that is an element of entries
   a. If $e$ is not empty then
      i. Set count to count+1.
8. Return count.

23.2.3.10 Set.prototype.values ( )

The following steps are taken:
1. Let $S$ be the this value.
2. If Type($S$) is not Object, then throw a TypeError exception.
3. Return the result of calling the CreateSetIterator abstract operation with argument $S$ and "value".

23.2.3.11 Set.prototype[@@iterator]( )

The initial value of the @@iterator property is the same function object as the initial value of the values property.

23.2.3.12 Set.prototype[@@toStringTag]

The initial value of the @@toStringTag property is the string value "Set".
This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

23.2.4 Properties of Set Instances

Set instances are ordinary objects that inherit properties from the Set.prototype. After initialisation by the Set constructor, Set instances also have a [[SetData]] internal data property and a [[SetComparator]] internal data property.

23.2.5 Set Iterator Object Structure

A Set Iterator is an ordinary object, with the structure defined below, that represents a specific iteration over some specific Set instance object. There is not a named constructor for Set Iterator objects. Instead, set iterator objects are created by calling certain methods of Set instance objects.

23.2.5.1 CreateSetIterator Abstract Operation

Several methods of Set objects return Iterator objects. The abstract operation CreateSetIterator with arguments set and kind is used to create such iterator objects. It performs the following steps:
1. Let $S$ be the result of calling ToObject(set).
2. ReturnIfAbrupt($S$).
3. If $S$ does not have a [[SetData]] internal data property throw a TypeError exception.
4. If $S$’s [[SetData]] internal data property is undefined, then throw a TypeError exception.
5. Let entries be the List that is the value of $S$’s [[SetData]] internal data property.
6. Let iterator be the result of ObjectCreate(%SetIteratorPrototype%, { [[IteratedSet]], [[SetNextIndex]], [[SetIterationKind]] }).
7. Set iterator’s [[IteratedSet]] internal data property to $S$.
8. Set iterator’s [[SetNextIndex]] internal data property to 0.
9. Set iterator’s [[SetIterationKind]] internal data property to kind.
10. Return iterator.
23.2.5.2 The Set Iterator Prototype

All Set Iterator Objects inherit properties from a common Set Iterator Prototype object. The [[Prototype]] internal data property of the Set Iterator Prototype is the %ObjectPrototype% intrinsic object. In addition, the Set Iterator Prototype has the following properties:

23.2.5.2.1 SetIterator.prototype.constructor

23.2.5.2.2 SetIterator.prototype.next( )

1. Let O be the this value.
2. If Type(O) is not Object, throw a TypeError exception.
3. If O does not have all of the internal properties of a Set Iterator Instance (23.2.5.3), throw a TypeError exception.
4. Let s be the value of the [[IteratedSet]] internal data property of O.
5. Let index be the value of the [[SetNextIndex]] internal data property of O.
6. Let itemKind be the value of the [[SetIterationKind]] internal data property of O.
7. Assert: s has a [[SetData]] internal data property and s has been initialised so the value of [[SetData]] is not undefined.
8. Let entries be the List that is the value of the [[SetData]] internal data property of s.
9. Repeat while index is less than the total number of elements of entries. The number of elements must be redetermined each time this method is evaluated.
   a. Let e be the element at 0-originated insertion position index of entries.
   b. Set index to index + 1;
   c. Set the [[SetNextIndex]] internal data property of O to index.
   d. If e is not empty, then
      i. If itemKind is "key+value" then
         1. Let result be the result of the abstract operation ArrayCreate with argument 2.
         2. Assert: result is a new, well-formed Array object so the following operations will never fail.
         3. Call CreateOwnDataProperty(result, "0", e).
         4. Call CreateOwnDataProperty(result, "1", e).
         5. Return CreateItrResultObject(result, false).
      ii. Return CreateItrResultObject(e, false).
10. Return CreateItrResultObject(undefined, true).

23.2.5.2.3 SetIterator.prototype.[@]iterator ( )

The following steps are taken:
1. Return the this value.

23.2.5.2.4 SetIterator.prototype.[@]toStringTag

The initial value of the @@toStringTag property is the string value "Set Iterator".

23.2.5.3 Properties of Set Iterator Instances

Set Iterator instances inherit properties from the Set Iterator prototype (the intrinsic, %SetIteratorPrototype%). Set Iterator instances are initially created with the internal properties specified Table 38.

<table>
<thead>
<tr>
<th>Internal Data Property Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[IteratedSet]</td>
<td>The Set object that is being iterated.</td>
</tr>
<tr>
<td>[SetNextIndex]</td>
<td>The integer index of the next Set data element to be examined by this iteration.</td>
</tr>
</tbody>
</table>
23.3 WeakMap Objects

WeakMap objects are collections of key/value pairs where the keys are ECMAScript objects and values may be arbitrary ECMAScript language values. A WeakMap may be queried to see if it contains a key/value pair with a specific key, but no mechanisms is provided for enumerating the objects it holds as keys. If an object that is being used as the key of a WeakMap key/value pair is only reachable by following a chain of references that start within that WeakMap, then that key/value pair is inaccessible and is automatically removed from the WeakMap. WeakMap implementations must detect and remove such key/value pairs and any associated resources.

An implementation may impose an arbitrarily determined latency between the time a key/value pair of a WeakMap becomes inaccessible and the time when the key/value pair is removed from the WeakMap. If this latency was observable to ECMAScript program, it would be a source of indeterminacy that could impact program execution. For that reason, an ECMAScript implementation must not provide any means to observe a key of a WeakMap that does not require the observer to present the observed key.

WeakMap objects must be implemented using either hash tables or other mechanisms that, on average, provide access times that are sublinear on the number of key/value pairs in the collection. The data structure used in this WeakMap objects specification are only intended to describe the required observable semantics of WeakMap objects. It is not intended to be a viable implementation model.

NOTE WeakMap and WeakSets are intended to provide mechanisms for dynamically associating state with an object in a manner that does not “leak” memory resources if, in the absence of the WeakMap or WeakSet, the object otherwise became inaccessible and subject to resource reclamation by the implementation’s garbage collection mechanisms. Achieving this characteristic requires coordination between the WeakMap or WeakSet implementation and the garbage collector. The following references describe mechanism that may be useful to implementations of WeakMap and WeakSets:

23.3.1 The WeakMap Constructor

The WeakMap constructor is the %WeakMap% intrinsic object and the initial value of the WeakMap property of the global object. When WeakMap is called as a function rather than as a constructor, it initialises its this value with the internal state necessary to support the WeakMap.prototype methods.

The WeakMap constructor is designed to be subclassable. It may be used as the value in an extends clause of a class definition. Subclass constructors that intend to inherit the specified WeakMap behaviour must include a super call to WeakMap.

23.3.1.1 WeakMap (iterable = undefined)

When the WeakMap function is called with optional argument iterable the following steps are taken:
1. Let map be the this value.
2. If Type(map) is not Object then, throw a TypeError exception.
3. If map does not have a [[WeakMapData]] internal data property, then throw a TypeError exception.
4. If map’s [[WeakMapData]] internal data property is not undefined, then throw a TypeError exception.
5. If iterable is not present, let iterable be undefined.
6. If iterable is either undefined or null, then let iter be undefined.
7. Else,
   a. Let iter be the result of GetIterator(iterable).
   b. ReturnIfAbrupt(iter).
   c. Let adder be the result of Get(map, "set").
   d. ReturnIfAbrupt(adder).
   e. If IsCallable(adder) is false, throw a TypeError Exception.
8. Set map’s [[WeakMapData]] internal data property to a new empty List.
9. If iter is undefined, then return map.
10. Repeat
    a. Let next be the result of IteratorNext(iter).
    b. ReturnIfAbrupt(next).
    c. Let done be IteratorComplete(next).
    d. ReturnIfAbrupt(done).
    e. If done is true, then return NormalCompletion(map).
    f. Let nextValue be IteratorValue(next).
    g. ReturnIfAbrupt(nextValue).
    h. If Type(nextValue) is not Object, then throw a TypeError execution.
    i. Let k be the result of Get(nextValue, "0").
    j. ReturnIfAbrupt(k).
    k. Let v be the result of Get(nextValue, "1").
    l. ReturnIfAbrupt(v).
    m. Let status be the result of calling the [[Call]] internal method of adder with map as thisArgument and a List whose elements are k and v as argumentsList.
    n. ReturnIfAbrupt(status).

NOTE If the parameter iterable is present, it is expected to be an object that implements an @@iterator method that returns an iterator object that produces two element array-like objects whose first element is a value that will be used as a WeakMap key and whose second element is the value to associate with that key.

23.3.1.2 new WeakMap(...) argumentsList

When WeakMap is called as part of a new expression it is a constructor: it initialises a newly created object.

WeakMap called as part of a new expression with argument list argumentsList performs the following steps:
1. Let F be the WeakMap function object on which the new operator was applied.
2. Let argumentsList be the argumentsList argument of the [[Construct]] internal method that was invoked by the new operator.
3. Return the result of OrdinaryConstruct(F, argumentsList).

If WeakMap is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.

23.3.2 Properties of the WeakMap Constructor

The value of the [[Prototype]] internal data property of the WeakMap constructor is the Function prototype object (19.2.3).

Besides the length property (whose value is 0), the WeakMap constructor has the following property:

23.3.2.1 WeakMap.prototype

The initial value of WeakMap.prototype is the WeakMap prototype object (23.3.3).
This property has the attributes `[[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false`.  

23.3.2.2 WeakMap[@@create]()

The `@@create` method of a WeakMap object `F` performs the following steps:

1. Let `F` be the `this` value.
2. Let `obj` be the result of calling `OrdinaryCreateFromConstructor(F, "%WeakMapPrototype").` 
3. Return `obj`.

This property has the attributes `[[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true`.

23.3.3 Properties of the WeakMap Prototype Object

The value of the `[[Prototype]]` internal data property of the WeakMap prototype object is the standard built-in `Object` prototype object (19.1.4). The WeakMap prototype object is an ordinary object. It does not have a `[[WeakMapData]]` internal data property.

23.3.3.1 WeakMap.prototype.clear()

The following steps are taken:

1. Let `M` be the `this` value.
2. If `Type(M)` is not `Object`, then throw a `TypeError` exception.
3. If `M` does not have a `[[WeakMapData]]` internal data property throw a `TypeError` exception.
4. If `M`’s `[[WeakMapData]]` internal data property is `undefined`, then throw a `TypeError` exception.
5. Set the value of `M`’s `[[WeakMapData]]` internal data property to a new empty `List`.
6. Return `undefined`.

23.3.3.2 WeakMap.prototype.constructor

The initial value of `WeakMap.prototype.constructor` is the built-in `WeakMap` constructor.

23.3.3.3 WeakMap.prototype.delete(key)

The following steps are taken:

1. Let `M` be the `this` value.
2. If `Type(M)` is not `Object`, then throw a `TypeError` exception.
3. If `M` does not have a `[[WeakMapData]]` internal data property throw a `TypeError` exception.
4. Let `entries` be the `List` that is the value of `M`’s `[[WeakMapData]]` internal data property.
5. If `entries` is `undefined`, then throw a `TypeError` exception.
6. If `Type(key)` is not `Object`, then throw a `TypeError` exception.
7. Repeat for each Record `[[[key]], [[value]]] p` that is an element of `entries`,
   a. If `p`’s `[[key]]` and `key` are the same object, then
      i. Set `p`’s `[[key]]` to `empty`.
      ii. Set `p`’s `[[value]]` to `empty`.
      iii. Return `true`.
8. Return `false`.

**NOTE** The value `empty` is used as a specification device to indicate that an entry has been deleted. Actual implementations may take other actions such as physically removing the entry from internal data structures.

23.3.3.4 WeakMap.prototype.get(key)

The following steps are taken:

1. Let `M` be the `this` value.
2. If Type(M) is not Object, then throw a TypeError exception.
3. If M does not have a [[WeakMapData]] internal data property throw a TypeError exception.
4. Let entries be the List that is the value of M's [[WeakMapData]] internal data property.
5. If entries is undefined, then throw a TypeError exception.
6. If Type(key) is not Object, then throw a TypeError exception.
7. Repeat for each Record ([[key]], [[value]]) p that is an element of entries,
   a. If p.[[key]] and key are the same object, then return p.[[value]]
8. Return undefined.

23.3.3.5 WeakMap.prototype.has(key)

The following steps are taken:
1. Let M be the this value.
2. If Type(M) is not Object, then throw a TypeError exception.
3. If M does not have a [[WeakMapData]] internal data property throw a TypeError exception.
4. Let entries be the List that is the value of M's [[WeakMapData]] internal data property.
5. If entries is undefined, then throw a TypeError exception.
6. If Type(key) is not Object, then throw a TypeError exception.
7. Repeat for each Record ([[key]], [[value]]) p that is an element of entries,
   a. If p.[[key]] and key are the same object, then return true
8. Return false.

23.3.3.6 WeakMap.prototype.set(key, value)

The following steps are taken:
1. Let M be the this value.
2. If Type(M) is not Object, then throw a TypeError exception.
3. If M does not have a [[WeakMapData]] internal data property throw a TypeError exception.
4. Let entries be the List that is the value of M's [[WeakMapData]] internal data property.
5. If entries is undefined, then throw a TypeError exception.
6. If Type(key) is not Object, then throw a TypeError exception.
7. Repeat for each Record ([[key]], [[value]]) p that is an element of entries,
   a. If p.[[key]] and key are the same object, then
      i. Set p.[[value]] to value
      ii. Return M
8. Let p be the Record ([[key]], [[value]]: value)
9. Append p as the last element of entries.
10. Return M.

23.3.3.7 WeakMap.prototype[@@toStringTag]

The initial value of the @@toStringTag property is the string value "WeakMap".
This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

23.3.4 Properties of WeakMap Instances

WeakMap instances are ordinary objects that inherit properties from the WeakMap prototype. WeakMap instances also have a [[WeakMapData]] internal data property.

23.4 WeakSet Objects

WeakSet objects are collections of ECMAScript objects. A distinct object may only occur once as an element of a WeakSet's collection. A WeakSet may be queried to see if it contains a specific object, but no mechanisms is provided for enumerating the objects it holds. If an object that is contain by a WeakSet is only reachable by following a chain of references that start within that WeakSet, then that object is inaccessible.
and is automatically removed from the WeakSet. WeakSet implementations must detect and remove such objects and any associated resources.

An implementation may impose an arbitrarily determined latency between the time an object contained in a WeakSet becomes inaccessible and the time when the object is removed from the WeakSet. If this latency was observable to ECMAScript program, it would be a source of indeterminacy that could impact program execution. For that reason, an ECMAScript implementation must not provide any means to determine if a WeakSet contains a particular object that does not require the observer to present the observed object.

WeakSet objects must be implemented using either hash tables or other mechanisms that, on average, provide access times that are sublinear on the number of elements in the collection. The data structure used in this WeakSet objects specification is only intended to describe the required observable semantics of WeakSet objects. It is not intended to be a viable implementation model.

NOTE See the NOTE in 23.3.

23.4.1 The WeakSet Constructor

The WeakSet constructor is the %WeakSet% intrinsic object and the initial value of the WeakSet property of the global object. When WeakSet is called as a function rather than as a constructor, it initialises its this value with the internal state necessary to support the WeakSet.prototype internal methods.

The WeakSet constructor is designed to be subclassable. It may be used as the value in an extends clause of a class definition. Subclass constructors that intend to inherit the specified WeakSet behaviour must include a super call to WeakSet.

23.4.1.1 WeakSet ( iterable = undefined )

When the WeakSet function is called with optional argument iterable the following steps are taken:

1. Let set be the this value.
2. If Type(set) is not Object then, throw a TypeError exception.
3. If set does not have a [[WeakSetData]] internal data property, then throw a TypeError exception.
4. If set’s [[WeakSetData]] internal data property is not undefined, then throw a TypeError exception.
5. If iterable is not present, let iterable be undefined.
6. If iterable is either undefined or null, then let iter be undefined.
7. Else,
   a. Let iter be the result of GetIterator(iterable).
   b. ReturnIfAbrupt(iter).
   c. Let adder be the result of Get(set, "add").
   d. ReturnIfAbrupt(adder).
   e. If IsCallable(adder) is false, throw a TypeError Exception.
8. Set set’s [[WeakSetData]] internal data property to a new empty List.
9. If iter is undefined, then return set.
10. Repeat
    a. Let next be the result of IteratorNext(iter).
    b. ReturnIfAbrupt(next).
    c. Let done be IteratorComplete(next).
    d. ReturnIfAbrupt(done).
    e. If done is true, then return NormalCompletion(set).
    f. Let nextValue be IteratorValue(next).
    g. ReturnIfAbrupt(nextValue).
    h. Let status be the result of calling the [[Call]] internal method of adder with set as thisArgument and a List whose sole element is nextValue as argumentsList.
    i. ReturnIfAbrupt(status).

23.4.1.2 new WeakSet ( ... argumentsList )

When WeakSet is called as part of a new expression it is a constructor: it initialises a newly created object.
WeakSet called as part of a new expression with argument list argumentsList performs the following steps:

1. Let F be the WeakSet function object on which the new operator was applied.
2. Let argumentsList be the argumentsList argument of the [[Construct]] internal method that was invoked by the new operator.
3. Return the result of OrdinaryConstruct(F, argumentsList).

If WeakSet is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.

23.4.2 Properties of the WeakSet Constructor

The value of the [[Prototype]] internal data property of the WeakSet constructor is the Function prototype object (19.2.3).

Besides the length property (whose value is 0), the WeakSet constructor has the following property:

23.4.2.1 WeakSet.prototype

The initial value of WeakSet.prototype is the intrinsic %WeakSetPrototype% object (23.4.3).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

23.4.2.2 WeakSet [[ @@create ]] ()

The @@create method of a WeakSet function object F performs the following steps:

1. Let F be the this value.
2. Let obj be the result of calling OrdinaryCreateFromConstructor(F, "%WeakSetPrototype%", ( [[WeakSetData]] )).
3. Return obj.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

23.4.3 Properties of the WeakSet Prototype Object

The value of the [[Prototype]] internal data property of the WeakSet prototype object is the standard built-in Object prototype object (19.1.4). The WeakSet prototype object is an ordinary object. It does not have a [[WeakSetData]] internal data property.

23.4.3.1 WeakSet.prototype.add (value)

The following steps are taken:

1. Let S be the this value.
2. If Type(S) is not Object, then throw a TypeError exception.
3. If S does not have a [[WeakSetData]] internal data property throw a TypeError exception.
4. If $S$’s [[WeakSetData]] internal data property is undefined, then throw a TypeError exception.
5. If Type(value) is not Object, then throw a TypeError exception.
6. Let entries be the List that is the value of S’s [[WeakSetData]] internal data property.
7. Repeat for each $e$ that is an element of entries, in original insertion order
   a. If $e$ is not empty and SameValue(e, value) is true, then
      i. Return S.
8. Append value as the last element of entries.
9. Return S.

23.4.3.2 WeakSet.prototype.clear ()

The following steps are taken:
1. Let $S$ be this value.
2. If Type($S$) is not Object, then throw a **TypeError** exception.
3. If $S$ does not have a [[WeakSetData]] internal data property throw a **TypeError** exception.
4. If $S$'s [[WeakSetData]] internal data property is `undefined`, then throw a **TypeError** exception.
5. Let *entries* be the List that is the value of $S$'s [[WeakSetData]] internal data property.
6. Repeat for each *e* that is an element of *entries*.
   a. Replace the element of *entries* whose value is *e* with an element whose value is **empty**.
7. Return **undefined**.

23.4.3.3 **WeakSet.prototype.constructor**

The initial value of WeakSet.prototype.constructor is the %WeakSet% intrinsic object.

23.4.3.4 **WeakSet.prototype.delete (value)**

The following steps are taken:

1. Let $S$ be the this value.
2. If Type($S$) is not Object, then throw a **TypeError** exception.
3. If $S$ does not have a [[WeakSetData]] internal data property throw a **TypeError** exception.
4. If $S$'s [[WeakSetData]] internal data property is `undefined`, then throw a **TypeError** exception.
5. If Type(*value*) is not Object, then throw a **TypeError** exception.
6. Let *entries* be the List that is the value of $S$'s [[WeakSetData]] internal data property.
7. Repeat for each *e* that is an element of *entries*, in original insertion order
   a. If *e* is not **empty** and SameValue(*e*, *value*) is **true**, then
      i. Replace the element of *entries* whose value is *e* with an element whose value is **empty**.
      ii. Return **true**.
8. Return **false**.

NOTE The value **empty** is used as a specification device to indicate that an entry has been deleted. Actual implementations may take other actions such as physically removing the entry from internal data structures.

23.4.3.5 **WeakSet.prototype.has (value)**

The following steps are taken:

1. Let $S$ be the this value.
2. If Type($S$) is not Object, then throw a **TypeError** exception.
3. If $S$ does not have a [[WeakSetData]] internal data property throw a **TypeError** exception.
4. If $S$'s [[WeakSetData]] internal data property is `undefined`, then throw a **TypeError** exception.
5. Let *entries* be the List that is the value of $S$'s [[WeakSetData]] internal data property.
6. Repeat for each *e* that is an element of *entries*.
   a. If *e* is not **empty** and SameValue(*e*, *value*), then return **true**.
7. Return **false**.

23.4.3.6 **WeakSet.prototype[ @@toStringTag ]**

The initial value of the @@toStringTag property is the string value "WeakSet".

This property has the attributes { [[Writable]]: **false**. [[Enumerable]]: **false**. [[Configurable]]: **true** }.

23.4.4 **Properties of WeakSet Instances**

WeakSet instances are ordinary objects that inherit properties from the WeakSet prototype. After initialisation by the WeakSet constructor, WeakSet instances also have a [[WeakSetData]] internal data property.
24 Structured Data

24.1 ArrayBuffer Objects

24.1.1 Abstract Operations For ArrayBuffer Objects

24.1.1.1 AllocateArrayBuffer(constructor)

The abstract operation AllocateArrayBuffer with argument constructor is used to create an uninitialised ArrayBuffer object. It performs the following steps:

1. Let obj be the result of calling OrdinaryCreateFromConstructor(constructor, “ArrayBufferPrototype”, ([ArrayBufferData], [ArrayBufferByteLength])).
2. ReturnIfAbrupt(obj).
3. Set the [[ArrayBufferByteLength]] internal data property of obj to 0.
4. Return obj.

24.1.1.2 SetArrayBufferData(arrayBuffer, bytes)

The abstract operation SetArrayBufferData with arguments arrayBuffer and bytes is used to initialise the storage block encapsulated by an ArrayBuffer object. It performs the following steps:

1. Assert: arrayBuffer has an [[ArrayBufferData]] internal data property.
2. Assert: bytes is a positive integer.
3. Let block be the result of CreateByteArrayBlock(bytes).
4. ReturnIfAbrupt(block).
5. Set arrayBuffer’s [[ArrayBufferData]] to block.
6. Set arrayBuffer’s [[ArrayBufferByteLength]] internal data property to bytes.
7. Return arrayBuffer.

24.1.1.3 CloneArrayBuffer(srcBuffer, srcByteOffset, srcType, cloneElementType, srcLength).

The abstract operation CloneArrayBuffer 24.1.1.3 takes four parameters, an ArrayBuffer srcBuffer, an integer srcByteOffset, a String srcType, a String cloneElementType, and integer srcLength. It creates a new ArrayBuffer containing the binary cloneElementType representation for srcLength elements convert from the corresponding srcType elements start at srcByteOffset within srcBuffer. This operation performs the following steps:

TODO: Write the algorithm

24.1.1.4 GetValueFromBuffer(arrayBuffer, byteIndex, type, isLittleEndian)

The abstract operation GetValueFromBuffer takes four parameters, an ArrayBuffer arrayBuffer, an integer byteIndex, a String type, and optionally a Boolean isLittleEndian. If isLittleEndian is not present, its default value is undefined. This operation performs the following steps:

1. Assert: There are sufficient bytes in arrayBuffer starting at byteIndex to represent a value of valueType.
2. Assert: byteIndex is a positive integer.
3. Let block be arrayBuffer’s [[ArrayBufferData]] internal data property.
4. If block is undefined or null, then throw a TypeError exception.
5. Let elementSize be the Number value of the Element Size value specified in Table 36 for valueType.
6. Let rawValue be the elementSize bytes starting at byteIndex of block.
7. If isLittleEndian is undefined, set isLittleEndian to either true or false. The choice is implementation dependent and should be the alternative that is most efficient for the implementation. An implementation must use the same value each time this step is executed and the same value must be used for the corresponding step in the SetValueInBuffer abstraction operation.
8. If isLittleEndian is false, reverse the order of the bytes of rawValue.
9. If type is “Float32”, then
   a. rawValue is interpreted as a little-endian bit string encoding of an IEEE 754-2008 binary32 value.
   b. If rawValue is an IEEE 754-2008 binary32 NaN value, return the NaN Number value.
c. Return the Number value that is encoded by rawValue.

10. If type is "Float32", then
    a. rawValue is interpreted as a little-endian bit string encoding of an IEEE 754-2008 binary32 value.
    b. If rawValue is an IEEE 754-2008 binary32 NaN value, return the NaN Number value.
    c. Return the Number value that is encoded by rawValue.

11. If the first character of type is "U", then
    a. Let intValue be the positive integer that is the result of interpreting rawValue as an unsigned little-endian binary number.
    b. Else, let intValue be the signed integer that is the result of interpreting rawValue as a little-endian binary 2's complement number of bit length elementSize × 8.
    c. Return intValue.

24.1.1.5 SetValueInBuffer (arrayBuffer, byteIndex, type, value, isLittleEndian)

The abstract operation SetValueInBuffer takes five parameters, an ArrayBuffer arrayBuffer, an integer byteIndex, a String type, a Number value, and optionally a Boolean isLittleEndian. If isLittleEndian is not present, its default value is undefined. This operation performs the following steps:

1. Assert: There are sufficient bytes in arrayBuffer starting at byteIndex to represent a value of valueType.
2. Assert: byteIndex is a positive integer.
3. Let block be arrayBuffer's [[ArrayBufferData]] internal data property.
4. If block is undefined or null, then throw a TypeError exception.
5. Let elementSize be the Number value of the Element Size value specified in the row with Element Type entry.
6. Let rawValue be the elementSize bytes starting at byteIndex of arrayBuffer.
7. If isLittleEndian is undefined, set isLittleEndian to either true or false. The choice is implementation dependent and an implementation may be the alternative that is most efficient for the implementation. An implementation must use the same value each time this step is executed and the same value must be used for the corresponding step in the GetValueFromBuffer abstraction operation.
8. If type is "Float32", then
    a. Set rawValue to the 4 bytes that are the result of converting value to IEEE-868-2005 binary32 format using “Round to nearest, ties to even” rounding mode. If isLittleEndian is false, the bytes are arranged in big endian order. Otherwise, the bytes are arranged in little endian order. If value is NaN, rawValue is may be set of any implementation chosen non-signaling NaN encoding.
9. Else, if type is "Float64", then
    a. Set rawValue to the 8 bytes that are the IEEE 868-2005 binary64 format encoding of value. If isLittleEndian is false, the bytes are arranged in big endian order. Otherwise, the bytes are arranged in little endian order. If value is NaN, rawValue is may be set of any implementation chosen non-signaling NaN encoding.
10. Else,
    a. Let n be the Size Element value in the row containing the value of type as its Element Type entry.
    b. Let convOp be the abstract operation named in the Conversion Operation column in the row containing the value of type as its Element Type entry.
    c. Let intValue be the result of calling convOp with value as its argument. 
    d. If intValue < 0, then
        i. Let rawBytes be the n-byte binary encoding of intValue. If isLittleEndian is false, the bytes are arranged in big endian order. Otherwise, the bytes are arranged in little endian order.
    e. Else,
        i. Let rawBytes be the n-byte binary 2's complement encoding of intValue. If isLittleEndian is false, the bytes are arranged in big endian order. Otherwise, the bytes are arranged in little endian order.
    f. Store the individual bytes of rawBytes in order starting at position byteIndex of block.
11. Return NormalCompletion (undefined).
24.1.2 The ArrayBuffer Constructor

The ArrayBuffer constructor is the %ArrayBuffer% intrinsic object and the initial value of the ArrayBuffer property of the global object. When ArrayBuffer is called as a function rather than as a constructor, its this value must be an Object with an [[ArrayBufferData]] internal data property whose value is undefined. The ArrayBuffer constructor initialises the this value using the argument values.

The ArrayBuffer constructor is designed to be subclassable. It may be used as the value of an extends clause of a class declaration. Subclass constructors that intended to inherit the specified ArrayBuffer behaviour must include a super call to the ArrayBuffer constructor to initialise subclass instances.

24.1.2.1 ArrayBuffer(length)

ArrayBuffer called as function with argument length performs the following steps:

1. Let O be the this value.
2. If Type(O) is not Object or if O does not have an [[ArrayBufferData]] internal data property or if the value of O's [[ArrayBufferData]] internal data property is not undefined, then
   a. Throw a TypeError exception.
3. Let numberLength be ToNumber(length).
4. Let byteLength be ToInteger(numberLength).
5. ReturnIfAbrupt(byteLength).
6. If numberLength ≠ byteLength or byteLength < 0, then throw a RangeError exception.
7. Return the result of SetArrayBufferData(O, byteLength).

24.1.2.2 new ArrayBuffer(...argumentsList)

ArrayBuffer called as part of a new expression performs the following steps:

1. Let F be the ArrayBuffer function object on which the new operator was applied.
2. Let argumentsList be the argumentsList argument of the [[Construct]] internal method that was invoked by the new operator.
3. Return the result of OrdinaryConstruct(F, argumentsList).

If ArrayBuffer is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.

24.1.3 Properties of the ArrayBuffer Constructor

The value of the [[Prototype]] internal data property of the ArrayBuffer constructor is the Function prototype object (19.2.3).

Besides its length property (whose value is 1), the ArrayBuffer constructor has the following properties:

24.1.3.1 ArrayBuffer.isView(arg)

The isView function takes one argument arg, and performs the following steps are taken:

1. If Type(arg) is not Object, return false.
2. If arg has a [[ViewedArrayBuffer]] internal data property, then return true.
3. If arg has a [[ViewedDataArrayBuffer]] internal data property, then return false.
4. Return false.

24.1.3.2 ArrayBuffer.prototype

The initial value of ArrayBuffer.prototype is the ArrayBuffer prototype object (24.1.4).

This property has the attributes ( [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false ).
24.1.3.3  \texttt{ArrayBuffer[@create]} ()

The \texttt{@create} method of a \texttt{ArrayBuffer} function object \texttt{F} performs the following steps:

1. Let \texttt{F} be the \texttt{this} value.
2. Return the result of calling \texttt{AllocateArrayBuffer(F)}.

This property has the attributes { \texttt{[Writable]}: false, \texttt{[Enumerable]}: false, \texttt{[Configurable]}: true }.

24.1.4  Properties of the \texttt{ArrayBuffer} Prototype Object

The value of the \texttt{[[Prototype]]} internal data property of the \texttt{ArrayBuffer} prototype object is the standard built-in \texttt{Object} prototype object (19.1.4). The \texttt{ArrayBuffer} prototype object is an ordinary object. It does not have a \texttt{[[ArrayBufferData]]} or \texttt{[[ArrayBufferByteLength]]} internal data property.

24.1.4.1  \texttt{get ArrayBuffer.prototype.byteLength}

\texttt{ArrayBuffer.prototype.byteLength} is an accessor property whose set accessor function is \texttt{undefined}. Its get accessor function performs the following steps:

1. Let \texttt{O} be the result of calling \texttt{ToObject} with the \texttt{this} value as its argument.
2. ReturnIfAbrupt(\texttt{O}).
3. If \texttt{O} does not have a \texttt{[[ArrayBufferData]]} internal data property throw a \texttt{TypeError} exception.
4. If the value of \texttt{O}'s \texttt{[[ArrayBufferData]]} internal data property is \texttt{undefined} or \texttt{null}, then throw a \texttt{TypeError} exception.
5. Let \texttt{length} be the value of \texttt{O}'s \texttt{[[ArrayBufferByteLength]]} internal data property.
6. Return \texttt{length}.

24.1.4.2  \texttt{ArrayBuffer.prototype.constructor}

The initial value of \texttt{ArrayBuffer.prototype.constructor} is the standard built-in \texttt{ArrayBuffer} constructor.

24.1.4.3  \texttt{ArrayBuffer.prototype.slice(start, end)}

The following steps are taken:

1. Let \texttt{O} be the result of calling \texttt{ToObject} with the \texttt{this} value as its argument.
2. ReturnIfAbrupt(\texttt{O}).
3. If \texttt{O} does not have a \texttt{[[ArrayBufferData]]} internal data property throw a \texttt{TypeError} exception.
4. If the value of \texttt{O}'s \texttt{[[ArrayBufferData]]} internal data property is \texttt{undefined} or \texttt{null}, then throw a \texttt{TypeError} exception.
5. Let \texttt{len} be the value of \texttt{O}'s \texttt{[[ArrayBufferByteLength]]} internal data property.
6. Let \texttt{relativeStart} be \texttt{ToInteger(start)}.
7. ReturnIfAbrupt(\texttt{relativeStart}).
8. If \texttt{relativeStart} is negative, let \texttt{first} be max((\texttt{len} + \texttt{relativeStart}),0); else let \texttt{first} be min(\texttt{relativeStart}, \texttt{len}).
9. If \texttt{end} is \texttt{undefined}, let \texttt{relativeEnd} be \texttt{len}; else let \texttt{relativeEnd} be \texttt{ToInteger(end)}.
10. ReturnIfAbrupt(\texttt{relativeEnd}).
11. If \texttt{relativeEnd} is negative, let \texttt{final} be max((\texttt{len} + \texttt{relativeEnd}),0); else let \texttt{final} be min(\texttt{relativeEnd}, \texttt{len}).
12. Let \texttt{newLen} be max(\texttt{final-first,0}).
13. Let \texttt{ctor} be the result of GetMethod(\texttt{O}, "\texttt{constructor}").
14. ReturnIfAbrupt(\texttt{ctor}).
15. If IsConstructor(\texttt{ctor}) is \texttt{false}, then throw a \texttt{TypeError} exception.
16. Let \texttt{new} be the result of calling the \texttt{[[Construct]]} internal method of \texttt{ctor} with a new list containing the single element \texttt{newLen}.
17. ReturnIfAbrupt(\texttt{new}).
18. If \texttt{new} does not have a \texttt{[[ArrayBufferData]]} internal data property throw a \texttt{TypeError} exception.
19. If the value of \texttt{new}'s \texttt{[[ArrayBufferData]]} internal data property is \texttt{undefined}, then throw a \texttt{TypeError} exception.
20. Let \texttt{fromBuf} be the value of \texttt{O}'s \texttt{[[ArrayBufferData]]} internal data property.
21. Let toBuf be the value of new’s [[ArrayBufferData]] internal data property.
22. Let status be the result of CopyBlockElements(fromBuf, first, toBuf, 0, newLen).
23. ReturnIfAbrupt(status).

24.1.4.4 ArrayBuffer.prototype[@@toStringTag]

The initial value of the [@@toStringTag] property is the string value "ArrayBuffer".

24.1.5 Properties of the ArrayBuffer Instances

ArrayBuffer instances inherit properties from the ArrayBuffer prototype object. ArrayBuffer instances each have a [[ArrayBufferData]] internal data property and a [[ArrayBufferByteLength]] internal data property.

ArrayBuffer instances whose [[ArrayBufferData]] is null are considered to be neutered and all operators to access or modify data contained in the ArrayBuffer instance will fail.

24.2 DataView Objects

24.2.1 Abstract Operations For DataView Objects

24.2.1.1 GetViewValue(view, requestIndex, isLittleEndian, type)

The abstract operation GetViewValue with arguments view, requestIndex, isLittleEndian, and type is used by functions on DataView instances to retrieve values from the view’s buffer. It performs the following steps:

1. Let v be ToObject(view).
2. ReturnIfAbrupt(v).
3. If v does not have a [[DataArrayBuffer]] internal data property, then throw a TypeError exception.
4. Let buffer be the value of v’s [[DataArrayBuffer]] internal data property.
5. If buffer is undefined, then throw a TypeError exception.
6. Let numberIndex be ToNumber(requestIndex).
7. Let getIndex be ToInteger(numberIndex).
8. ReturnIfAbrupt(getIndex).
9. If numberIndex ≠ getIndex or getIndex < 0, then throw a RangeError exception.
10. Let isLittleEndian be ToBoolean(isLittleEndian).
11. ReturnIfAbrupt(isLittleEndian).
12. Let viewOffset be the value of v’s [[ByteOffset]] internal data property.
13. Let viewSize be the value of v’s [[ByteLength]] internal data property.
14. Let elementSize be the Number value of the Element Size value specified in Table 36 for type.
15. If numberIndex + elementSize > viewSize, then throw a RangeError exception.
16. Let bufferIndex be getIndex + viewOffset.
17. Return the result of GetValueFromBuffer(buffer, bufferIndex, type, isLittleEndian).

24.2.1.2 SetViewValue(view, requestIndex, isLittleEndian, type, value)

The abstract operation SetViewValue with arguments view, requestIndex, isLittleEndian, type, and value is used by functions on DataView instances to store values into the view’s buffer. It performs the following steps:

1. Let v be ToObject(view).
2. ReturnIfAbrupt(v).
3. If v does not have a [[DataArrayBuffer]] internal data property, then throw a TypeError exception.
4. Let buffer be the value of v’s [[DataArrayBuffer]] internal data property.
5. If buffer is undefined, then throw a TypeError exception.
6. Let numberIndex be ToNumber(requestIndex).
7. Let getIndex be ToInteger(numberIndex).
8. ReturnIfAbrupt(getIndex).
9. If numberIndex ≠ getIndex or getIndex < 0, then throw a RangeError exception.
10. Let isLittleEndian be ToBoolean(isLittleEndian).

Commented [AWB13193]: TODO: need to define abstract operations for allocating and manipulating data blocks.
11. ReturnIfAbrupt(isLittleEndian).
12. Let viewOffset be the value of ν’s [[ByteOffset]] internal data property.
13. Let viewSize be the value of ν’s [[ByteLength]] internal data property.
14. Let elementSize be the Number value of the Element Size value specified in Table 36 for type.
15. If getIndex + elementSize > viewSize, then throw a RangeError exception.
16. Let bufferIndex be getIndex+viewOffset.
17. Return the result of SetValueInBuffer(buffer, bufferIndex, type, value, isLittleEndian).

NOTE The algorithms for GetViewValue and SetViewValue are identical except for their final steps.

24.2.2 The DataView Constructor

When DataView is called as a function rather than as a constructor, it creates and initialises a new DataView object. Thus the function call DataView(...) is equivalent to the object creation expression new DataView(...) with the same arguments. However, if the this value value passed in the call is an Object with an [[ArrayBufferData]] internal data property whose value is undefined, it initializes the this value using the argument values. This permits DataView to be used both as factory method and to perform constructor instance initialization.

The DataView constructor is designed to be subclassable. It may be used as the value of an extends clause of a class declaration. Subclass constructors that intended to inherit the specified DataView behaviour must include a super call to the DataView constructor to initialise subclass instances.

24.2.2.1 DataView(buffer, byteOffset=0, byteLength=undefined)

DataView called with arguments buffer, byteOffset, and length performs the following steps:

1. Let O be the this value.
2. If Type(O) is not Object or if O does not have an [[ArrayBufferData]] internal data property or if the value of O’s [[ArrayBufferData]] internal data property is not undefined, then
   a. Let F be this function object.
   b. Let argumentsList be the argumentsList argument of the [[Call]] internal method that invoked F.
   c. Return the result of calling OrdinaryConstruct(F, argumentsList).
3. If Type(buffer) is not Object, then throw a TypeError exception.
4. If buffer does not have a [[ArrayBufferData]] internal data property, then throw a TypeError exception.
5. Let numberOffset be ToNumber(byteOffset).
6. Let offset be ToInteger(numberOffset).
7. ReturnIfAbrupt(offset).
8. If numberOffset ≠ offset or offset < 0, then throw a RangeError exception.
9. Let bufferByteLength be the value of buffer’s [[ArrayBufferData]] internal data property.
10. If offset > bufferByteLength, then throw a RangeError exception.
11. If byteLength is undefined, then
   a. Let viewByteLength be bufferByteLength – offset.
12. Else,
   a. Let numberLength be ToNumber(byteLength).
   b. Let viewLength be ToInteger(numberLength).
   c. ReturnIfAbrupt(viewLength).
   d. If numberLength ≠ viewLength or viewLength < 0, then throw a RangeError exception.
   e. Let viewByteLength be viewLength.
   f. If offset+viewByteLength > bufferByteLength, then throw a RangeError exception.
13. If the value of O’s [[ArrayBufferData]] internal data property is not undefined, then throw a TypeError exception.
14. Set O’s [[ArrayBufferData]] to buffer.
15. Set O’s [[ByteLength]] internal data property to viewByteLength.
16. Set O’s [[ByteOffset]] internal data property to offset.
17. Return O.
24.2.2.2 new DataView( ... argumentsList)

DataView called as part of a new expression it performs the following steps:

1. Let F be the function object on which the new operator was applied.
2. Let argumentsList be the argumentsList argument of the [[Construct]] internal method that was invoked by the new operator.
3. Return the result of OrdinaryConstruct(F, argumentsList).

If DataView is implemented as an ordinary function object, its [[Construct]] internal method will perform the above steps.

24.2.3 Properties of the DataView Constructor

The value of the [[Prototype]] internal data property of the DataView constructor is the Function prototype object (19.2.3).

Besides the internal properties and the length property (whose value is 3), the DataView constructor has the following properties:

24.2.3.1 DataView.prototype

The initial value of DataView.prototype is the DataView prototype object (24.2.4).

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

24.2.3.2 DataView @@create ( )

The @@create method of a DataView function object F performs the following steps:

1. Let F be the this value.
2. Let obj be the result of calling OrdinaryCreateFromConstructor(F, "%DataViewPrototype%", ([[[DataArrayBuffer]]], [[ByteLength]], [[ByteOffset]])).
3. Return obj.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

24.2.4 Properties of the DataView Prototype Object

The value of the [[Prototype]] internal data property of the DataView prototype object is the standard built-in Object prototype object (19.1.4). The DataView prototype object is an ordinary object. It does not have a [[DataArrayBuffer]], [[ByteLength]], or [[ByteOffset]] internal data property.

24.2.4.1 get DataView.prototype.buffer

DataView.prototype.buffer is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let O be the result of calling ToObject with the this value as its argument.
2. ReturnIfAbrupt(O).
3. If O does not have a [[DataArrayBuffer]] internal data property throw a TypeError exception.
4. Let buffer be the value of O’s [[DataArrayBuffer]] internal data property.
5. If buffer is undefined, then throw a TypeError exception.
6. Return buffer.

Commented [AWB13194]: buffer needs to be an accessor both to comply with WebIDL requirements and to support the Kronos neutering strawman requirements.

24.2.4.2 get DataView.prototype.byteLength

DataView.prototype.byteLength is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

Commented [AWB13195]: buffer needs to be an accessor both to comply with WebIDL requirements and to support the Kronos neutering strawman requirements.
1. Let \( O \) be the result of calling ToObject with the this value as its argument.
2. ReturnIfAbrupt(\( O \)).
3. If \( O \) does not have a [[DataArrayBuffer]] internal data property throw a TypeError exception.
4. Let buffer be the value of \( O \)'s [[ViewedDataArrayBuffer]] internal data property.
5. If buffer is undefined, then throw a TypeError exception.
6. Let size be the value of \( O \)'s [[ByteLength]] internal data property.
7. Return size.

24.2.4.3 `get DataView.prototype.byteOffset`

DataView.prototype.byteOffset is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let \( O \) be the result of calling ToObject with the this value as its argument.
2. ReturnIfAbrupt(\( O \)).
3. If \( O \) does not have a [[DataArrayBuffer]] internal data property throw a TypeError exception.
4. Let buffer be the value of \( O \)'s [[DataArrayBuffer]] internal data property.
5. If buffer is undefined, then throw a TypeError exception.
6. Let offset be the value of \( O \)'s [[ByteOffset]] internal data property.
7. Return offset.

24.2.4.4 DataView.prototype.constructor

The initial value of DataView.prototype.constructor is the standard built-in DataView constructor.

24.2.4.5 DataView.prototype.getFloat32(byteOffset, littleEndian=false)

When the `get Float32` method is called with argument `byteOffset` and optional argument `littleEndian` the following steps are taken:

1. Let \( v \) be the this value.
2. If littleEndianness is not present, then let littleEndianness be false.
3. Return the result of GetViewValue(\( v \), byteOffset, littleEndianness, "Float32").

24.2.4.6 DataView.prototype.getFloat64(byteOffset, littleEndian=false)

When the `get Float64` method is called with argument `byteOffset` and optional argument `littleEndian` the following steps are taken:

1. Let \( v \) be the this value.
2. If littleEndianness is not present, then let littleEndianness be false.
3. Return the result of GetViewValue(\( v \), byteOffset, littleEndianness, "Float64").

24.2.4.7 DataView.prototype.getInt8(byteOffset)

When the `getInt8` method is called with argument `byteOffset` the following steps are taken:

1. Let \( v \) be the this value.
2. Return the result of GetViewValue(\( v \), byteOffset, undefined, "Int8").

24.2.4.8 DataView.prototype.getInt16(byteOffset, littleEndian=false)

When the `getInt16` method is called with argument `byteOffset` and optional argument `littleEndian` the following steps are taken:

1. Let \( v \) be the this value.
2. If littleEndianness is not present, then let littleEndianness be false.
3. Return the result of GetViewValue(\( v \), byteOffset, littleEndianness, "Int16").
24.2.4.9 DataView.prototype.getInt32(byteOffset, littleEndian=false)

When the `getInt32` method is called with argument `byteOffset` and optional argument `littleEndian` the following steps are taken:

1. Let `v` be the this value.
2. If `littleEndian` is not present, then let `littleEndian` be `undefined`.
3. Return the result of `GetViewValue(v, byteOffset, littleEndian, "Int32")`.

24.2.4.10 DataView.prototype.getUint8(byteOffset)

When the `getUint8` method is called with argument `byteOffset` the following steps are taken:

1. Let `v` be the this value.
2. Return the result of `GetViewValue(v, byteOffset, undefined, "Uint8")`.

24.2.4.11 DataView.prototype.getUint16(byteOffset, littleEndian=false)

When the `getUint16` method is called with argument `byteOffset` and optional argument `littleEndian` the following steps are taken:

1. Let `v` be the this value.
2. If `littleEndian` is not present, then let `littleEndian` be `false`.
3. Return the result of `GetViewValue(v, byteOffset, littleEndian, "Uint16")`.

24.2.4.12 DataView.prototype.getUint32(byteOffset, littleEndian=false)

When the `getUint32` method is called with argument `byteOffset` and optional argument `littleEndian` the following steps are taken:

1. Let `v` be the this value.
2. If `littleEndian` is not present, then let `littleEndian` be `false`.
3. Return the result of `GetViewValue(v, byteOffset, littleEndian, "Uint32")`.

24.2.4.13 DataView.prototype.setFloat32(byteOffset, value, littleEndian=false)

When the `setFloat32` method is called with arguments `byteOffset` and `value` and optional argument `littleEndian` the following steps are taken:

1. Let `v` be the this value.
2. If `littleEndian` is not present, then let `littleEndian` be `false`.
3. Return the result of `SetViewValue(v, byteOffset, littleEndian, "Float32", value)`.

24.2.4.14 DataView.prototype.setFloat64(byteOffset, value, littleEndian=false)

When the `setFloat64` method is called with arguments `byteOffset` and `value` and optional argument `littleEndian` the following steps are taken:

1. Let `v` be the this value.
2. If `littleEndian` is not present, then let `littleEndian` be `false`.
3. Return the result of `SetViewValue(v, byteOffset, littleEndian, "Float64", value)`.

24.2.4.15 DataView.prototype.setInt8(byteOffset, value)

When the `setInt8` method is called with arguments `byteOffset` and `value` the following steps are taken:

1. Let `v` be the this value.
2. Return the result of `SetViewValue(v, byteOffset, undefined, "Int8", value)`.
24.2.4.16 DataView.prototype.setInt16(byteOffset, value, littleEndian=false)

When the setInt16 method is called with arguments byteOffset and value and optional argument littleEndian the following steps are taken:

1. Let v be the this value.
2. If littleEndian is not present, then let littleEndian be false.
3. Return the result of SetViewValue(v, byteOffset, littleEndian, "Int16", value).

24.2.4.17 DataView.prototype.setInt32(byteOffset, value, littleEndian=false)

When the setInt32 method is called with arguments byteOffset and value and optional argument littleEndian the following steps are taken:

1. Let v be the this value.
2. If littleEndian is not present, then let littleEndian be false.
3. Return the result of SetViewValue(v, byteOffset, littleEndian, "Int32", value).

24.2.4.18 DataView.prototype.setUint8(byteOffset, value)

When the setUint8 method is called with arguments byteOffset and value the following steps are taken:

1. Let v be the this value.
2. Return the result of SetViewValue(v, byteOffset, undefined, "Uint8", value).

24.2.4.19 DataView.prototype.setUint16(byteOffset, value, littleEndian=false)

When the setUint16 method is called with arguments byteOffset and value and optional argument littleEndian the following steps are taken:

1. Let v be the this value.
2. If littleEndian is not present, then let littleEndian be false.
3. Return the result of SetViewValue(v, byteOffset, littleEndian, "Uint16", value).

24.2.4.20 DataView.prototype.setUint32(byteOffset, value, littleEndian=false)

When the setUint32 method is called with arguments byteOffset and value and optional argument littleEndian the following steps are taken:

1. Let v be the this value.
2. If littleEndian is not present, then let littleEndian be false.
3. Return the result of SetViewValue(v, byteOffset, littleEndian, "Uint32", value).

24.2.4.21 DataView.prototype[ @@toStringTag ]

The initial value of the @@toStringTag property is the string value "DataView".

24.2.5 Properties of DataView Instances

DataView instances are ordinary objects that inherit properties from the DataView prototype object. DataView instances each have a [[DataArrayBuffer]], [[ByteLength]], and [[ByteOffset]] internal data properties.

24.3 The JSON Object

The JSON object is a single ordinary object that contains two functions, parse and stringify, that are used to parse and construct JSON texts. The JSON Data Interchange Format is described in RFC 4627 <http://www.ietf.org/rfc/rfc4627.txt>. The JSON interchange format used in this specification is exactly that described by RFC 4627 with two exceptions:
The top level JSONText production of the ECMAScript JSON grammar may consist of any JSONValue rather than being restricted to being a JSONObject or a JSONArray as specified by RFC 4627.

Conforming implementations of JSON.parse and JSON.stringify must support the exact interchange format described in this specification without any deletions or extensions to the format. This differs from RFC 4627 which permits a JSON parser to accept non-JSON forms and extensions.

The value of the [[Prototype]] internal data property of the JSON object is the standard built-in Object prototype object (19.1.4). The JSON object has a [[JSONTag]] internal data property whose value is true. The value of the [[Extensible]] internal data property of the JSON object is set to true.

The JSON object does not have a [[Construct]] internal method; it is not possible to use the JSON object as a constructor with the new operator.

The JSON object does not have a [[Call]] internal method; it is not possible to invoke the JSON object as a function.

24.3.1 The JSON Grammar

JSON.stringify produces a String that conforms to the following JSON grammar. JSON.parse accepts a String that conforms to the JSON grammar.

24.3.1.1 The JSON Lexical Grammar

JSON is similar to ECMAScript source text in that it consists of a sequence of Unicode characters conforming to the rules of SourceCharacter. The JSON Lexical Grammar defines the tokens that make up a JSON text similar to the manner that the ECMAScript lexical grammar defines the tokens of an ECMAScript source text.

The JSON lexical grammar only recognizes the white space character specified by the production JSONWhiteSpace. The JSON lexical grammar shares some productions with the ECMAScript lexical grammar.

All nonterminal symbols of the grammar that do not begin with the characters “JSON” are defined by productions of the ECMAScript lexical grammar.

Syntax

JSONWhiteSpace ::
<TAB>
<CR>
<LF>
<SP>

JSONString ::
" JSONStringCharactersopt "

JSONStringCharacters ::
JSONStringCharacter JSONStringCharactersopt

JSONStringCharacter ::
SourceCharacter but not one of " or \ or U+0000 through U+001F \ JSONEscapeSequence

JSONEscapeSequence ::
JSONEscapeCharacter
a HexDigit HexDigit HexDigit HexDigit

JSONEscapeCharacter :: one of
a " / \ b f n r t

JSONNumber ::
-opt DecimalIntegerLiteral JSONFractionopt ExponentPartopt
JSONFraction ::
  . DecimalDigits

JSONNullLiteral ::
  NullLiteral

JSONBooleanLiteral ::
  BooleanLiteral

24.3.1.2 The JSON Syntactic Grammar

The JSON Syntactic Grammar defines a valid JSON text in terms of tokens defined by the JSON lexical grammar. The goal symbol of the grammar is JSONText.

Syntax

JSONText :
  JSONValue

JSONValue :
  JSONNullLiteral
  JSONBooleanLiteral
  JSONObject
  JSONArray
  JSONString
  JSONNumber

JSONObject :
  { }
  { JSONMemberList }

JSONMember :
  JSONString : JSONValue

JSONMemberList :
  JSONMember
  JSONMemberList , JSONMember

JSONArray :
  [ ]
  [ JSONElementList ]

JSONElementList :
  JSONValue
  JSONElementList , JSONValue

24.3.2 JSON.parse (text [, reviver])

The parse function parses a JSON text (a JSON-formatted String) and produces an ECMAScript value. The JSON format is a restricted form of ECMAScript literal. JSON objects are realized as ECMAScript objects. JSON arrays are realized as ECMAScript arrays. JSON strings, numbers, booleans, and null are realized as ECMAScript Strings, Numbers, Booleans, and null. JSON uses a more limited set of white space characters than WhiteSpace and allows Unicode code points U+2028 and U+2029 to directly appear in JSONString literals without using an escape sequence. The process of parsing is similar to 12.1.4.1 and 12.1.5 as constrained by the JSON grammar.

The optional reviver parameter is a function that takes two parameters, (key and value). It can filter and transform the results. It is called with each of the key/value pairs produced by the parse, and its return value is used instead of the original value. If it returns undefined then the property is deleted from the result.
1. Let \( J\text{Text} \) be \( \text{ToString}(\text{text}) \).
2. ReturnIfAbrupt(\( J\text{Text} \)).
3. Parse \( J\text{Text} \) interpreted as UTF-16 encoded Unicode characters using the grammars in 24.3.1. Throw a SyntaxError exception if \( J\text{Text} \) did not conform to the JSON grammar for the goal symbol JSONText.
4. Let \( \text{scriptText} \) be the result of concatenating " (\( J\text{Text} \), and *)".
5. Let completion be the result of parsing and evaluating \( \text{scriptText} \) as if it was the source text of an ECMAScript Script but using JSONString in place of StringLiteral. Throw a SyntaxError exception if \( J\text{Text} \) did not conform to the JSON grammar for the goal symbol JSONText.
6. Return unfiltered.
7. If IsCallable(reviver) is true, then
   a. Let root be the result of the abstract operation ObjectCreate with the intrinsic object %ObjectPrototype% as its argument.
   b. Call CreateOwnDataProperty(root, the empty String, unfiltered).
   c. Return the result of calling the abstract operation Walk, passing root and the empty String. The abstract operation Walk is described below.
8. Else
   a. Return unfiltered.

Runtime Semantics: Walk Abstract Operation

The abstract operation Walk is a recursive abstract operation that takes two parameters: a holder object and the String name of a property in that object. Walk uses the value of reviver that was originally passed to the above parse function.

1. Let val be the result of Get(holder, name).
2. ReturnIfAbrupt(val).
3. If val is an object, then
   a. If val is an exotic Array object then
      i. Set \( I \) to 0.
      ii. Let len be the result of Get(val, "\( I \)length").
      iii. Assert: len is not an abrupt completion and its value is a positive integer.
      iv. Repeat while \( I < \) len,
         1. Let newElement be the result of calling the abstract operation Walk, passing val and ToString(I).
         2. If newElement is undefined, then
            a. Let status be the result of calling the [[Delete]] internal method of val with ToString(I) as the argument.
            b. NOTE This algorithm intentionally does not throw an exception if status is false.
            4. ReturnIfAbrupt(status).
            5. Add 1 to \( I \).
      b. Else
         i. Let keys be an internal List of String values consisting of the names of all the own properties of val whose [[Enumerable]] attribute is true. The ordering of the Strings is the same as that used by the Object.keys standard built-in function.
         ii. For each String \( P \) in keys do,
            1. Let newElement be the result of calling the abstract operation Walk, passing val and \( P \).
            2. If newElement is undefined, then
               a. Let status be the result of calling the [[Delete]] internal method of val with \( P \) as the argument.
               3. Else
                  a. Let status be the result of calling the [[DefineOwnProperty]] internal method of val with arguments \( P \) and Property Descriptor {
                     [[Value]]: newElement, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}.

        3. Else
```
newElement, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true).

b. NOTE This algorithm intentionally does not throw an exception if status is false.

4. ReturnIfAbrupt(status).

4. Return the result of calling the [[Call]] internal method of reviver passing holder as thisArgument and with a List containing name and val as argumentsList.

It is not permitted for a conforming implementation of JSON.parse to extend the JSON grammars. If an implementation wishes to support a modified or extended JSON interchange format it must do so by defining a different parse function.

NOTE In the case where there are duplicate name Strings within an object, lexically preceding values for the same key shall be overwritten.

24.3.3 JSON.stringify (value [, replacer [, space ]])

The stringify function returns a String in UTF-16 encoded JSON format representing an ECMAScript value. It can take three parameters. The value parameter is an ECMAScript value, which is usually an object or array, although it can also be a String, Boolean, Number or null. The optional replacer parameter is either a function that alters the way objects and arrays are stringified, or an array of Strings and Numbers that acts as a white list for selecting the object properties that will be stringified. The optional space parameter is a String or Number that allows the result to have white space injected into it to improve human readability.

These are the steps in stringifying an object:

1. Let stack be an empty List.
2. Let indent be the empty String.
3. Let PropertyList and ReplacerFunction be undefined.
4. If Type(replacer) is Object, then
   a. If IsCallable(replacer) is true, then
      i. Let ReplacerFunction be replacer,
   b. Else if replacer is an exotic Array object, then
      i. Let PropertyList be an empty internal List
      ii. For each value v of a property of replacer that has an array index property name. The properties are enumerated in the ascending array index order of their names.
      1. Let item be undefined.
      2. If Type(v) is String then let item be v.
      3. Else if Type(v) is Number then let item be ToString(v).
      4. Else if Type(v) is Object then,
         a. If it has a [[StringData]] or [[NumberData]] internal data property, then
         b. Let item be ToString(v).
      5. If item is not undefined and item is not currently an element of PropertyList then,
         a. Append item to the end of PropertyList.
   5. If Type(space) is Object then,
      a. If space has a [[NumberData]] internal data property then,
         a. Let space be ToInteger(space).
      b. Else if space has a [[StringData]] internal data property then,
         i. Let space be ToString(space).
   6. If Type(space) is Number
      a. Let space be min(10, ToInteger(space)).
      b. Set gap to a String containing space occurrences of code unit 0x0020 (the Unicode space character). This will be the empty String if space is less than 1.
   7. Else if Type(space) is String
      a. If the number of elements in space is 10 or less, set gap to space otherwise set gap to a String consisting of the first 10 elements of space.
   8. Else
      a. Set gap to the empty String.
   9. Let wrapper be the result of the abstract operation ObjectCreate with the intrinsic object %ObjectPrototype% as its argument.
10. Call CreateOwnDataProperty(wrapper, the empty String, value).
```
11. Return the result of calling the abstract operation \texttt{Str} with the empty String and \texttt{wrapper}.

\textbf{Runtime Semantics: Str Abstract Operation}

The abstract operation \texttt{Str(key, holder)} has access to \texttt{ReplacerFunction} from the invocation of the \texttt{stringify} method. Its algorithm is as follows:

1. Let \textit{value} be the result of \texttt{Get(holder, key)}.
2. ReturnIfAbrupt(\textit{value}).
3. If \texttt{Type(\textit{value})} is Object, then
   a. Let \textit{value} be the result of \texttt{Get(\textit{value}, \texttt{JSON})}.
   b. If IsCallable(to\texttt{JSON}) is true
      i. Let \textit{value} be the result of calling the [[Call]] internal method of to\texttt{JSON} passing \textit{value} as this\texttt{Argument} and a List containing key as arguments\texttt{List}.
   ii. ReturnIfAbrupt(\textit{value}).
4. If \texttt{ReplacerFunction} is not undefined, then
   a. Let \textit{value} be the result of calling the [[Call]] internal method of \texttt{ReplacerFunction} passing \textit{holder} as the this\texttt{value} and with an argument list consisting of key and value.
   b. ReturnIfAbrupt(\textit{value}).
5. If Type(\textit{value}) is Object then,
   a. If \textit{value} has an [[NumberData]] internal data property then,
      i. Let \textit{value} be ToNumber(\textit{value}).
   b. Else if \textit{value} has an [[StringData]] internal data property then,
      i. Let \textit{value} be To\texttt{String}(\textit{value}).
   c. Else if \textit{value} has an [[BooleanData]] internal data property then,
      i. Let \textit{value} be the value of the [[BooleanData]] internal data property of \textit{value}.
6. If \textit{value} is \texttt{null} then return "null".
7. If \textit{value} is \texttt{true} then return "true".
8. If \textit{value} is \texttt{false} then return "false".
9. If Type(\textit{value}) is String, then return the result of calling the abstract operation \texttt{Quote} with argument value.
10. If Type(\textit{value}) is Number
    a. If \textit{value} is finite then return To\texttt{String}(\textit{value}).
    b. Else, return "null".
11. If Type(\textit{value}) is Object, and IsCallable(\textit{value}) is false
    a. If \textit{value} is an exotic Array object then
       i. Return the result of calling the abstract operation \texttt{JA} with argument value.
    b. Else, return the result of calling the abstract operation \texttt{JO} with argument value.
12. Return undefined.

\textbf{Runtime Semantics: Quote Abstract Operation}

The abstract operation \texttt{Quote(\textit{value})} wraps a String value in double quotes and escapes characters within it.

1. Let product be code unit 0x0022 (the Unicode double quote character).
2. For each code unit \textit{C} in \textit{value}
   a. If \textit{C} is 0x0022 or 0x005C (the Unicode reverse solidus character)
      i. Let product be the concatenation of product and code unit 0x005C.
   ii. Let product be the concatenation of product and \textit{C}.
   b. Else if \textit{C} is backspace, formfeed, newline, carriage return, or tab
      i. Let product be the concatenation of product and code unit 0x005C (the Unicode backslash character).
      ii. Let abbrev be the string value corresponding to the value of \textit{C} as follows:
          backspace "b"
          formfeed "f"
          newline "n"
          carriage return "r"
          tab "t"
      iii. Let product be the concatenation of product and abbrev.
   c. Else if \textit{C} has a code unit value less than 0x0020 (the Unicode space character)
i. Let product be the concatenation of product and code unit 0x005C (the Unicode backslash character).
ii. Let product be the concatenation of product and "\".
iii. Let hex be the string result of converting the numeric code unit value of C to a String of four hexadecimal digits. Alphabetic hexadecimal digits are presented as lowercase characters.
iv. Let product be the concatenation of product and hex.
v. Else
   i. Let product be the concatenation of product and C.
3. Let product be the concatenation of product and code unit 0x0022 (the Unicode double quote character).
4. Return product.

Runtime Semantics: JO Abstract Operation

The abstract operation JO(value) serializes an object. It has access to the stack, indent, gap, and PropertyList of the invocation of the stringifying method.

1. If stack contains value then throw a TypeError exception because the structure is cyclical.
2. Append value to stack.
3. Let stepback be indent.
4. Let indent be the concatenation of indent and gap.
5. If PropertyList is not undefined then
   a. Let K be PropertyList.
6. Else
   a. Let K be an internal List of Strings consisting of the keys of all the own properties of value whose [[Enumerable]] attribute is true and whose property key is a String value. The ordering of the Strings is the same as that used by the Object.keys standard built-in function.
7. Let partial be an empty List.
8. For each element P of K,
   a. Let strP be the result of calling the abstract operation Str with arguments P and value.
   b. ReturnIfAbrupt(strP).
   c. If strP is not undefined
      i. Let member be the result of calling the abstract operation Quote with argument P.
      ii. Let member be the concatenation of member and the string ": ".
      iii. If gap is not the empty String
           1. Let member be the concatenation of member and code unit 0x0020 (the Unicode space character).
           iv. Let member be the concatenation of member and strP.
           v. Append member to partial.
9. If partial is empty then
   a. Let final be "{}".
10. Else
    a. If gap is the empty String
       i. Let properties be a String formed by concatenating all the element Strings of partial with each adjacent pair of Strings separated with code unit 0x002C (the Unicode comma character). A comma is not inserted either before the first String or after the last String.
       ii. Let final be the result of concatenating "{" , properties, and "}". 
    b. Else gap is not the empty String 
       i. Let separator be the result of concatenating code unit 0x002C (the comma character), code unit 0x000A (the line feed character), and indent.
       ii. Let properties be a String formed by concatenating all the element Strings of partial with each adjacent pair of Strings separated with separator. The separator String is not inserted either before the first String or after the last String.
       iii. Let final be the result of concatenating "{", code unit 0x000A (the line feed character), indent, properties, code unit 0x000A, stepback, and "}".
11. Remove the last element of stack.
12. Let indent be stepback.

Runtime Semantics: JA Abstract Operation
The abstract operation JA(value) serializes an array. It has access to the stack, indent, and gap of the invocation of the stringify method. The representation of arrays includes only the elements between zero and array.length – 1 inclusive. Properties whose keys are not array indexes are excluded from the serialization. An array is stringified as an open left bracket, elements separated by comma, and a closing right bracket.

1. If stack contains value then throw a TypeError exception because the structure is cyclical.
2. Append value to stack.
3. Let stepback be indent.
4. Let indent be the concatenation of indent and gap.
5. Let partial be an empty List.
6. Assert: value is a standard array object and hence its "length" property is a non-negative integer.
7. Let lenVal be the result of Get(value, "length")
8. Let len be ToLength(lenVal).
9. ReturnIfAbrupt(len).
10. Let index be 0.
11. Repeat while index < len
   a. Let strP be the result of calling the abstract operation Str with arguments ToString(index) and value.
   b. ReturnIfAbrupt(strP).
   c. If strP is undefined
      i. Append "null" to partial.
   d. Else
      i. Append strP to partial.
   e. Increment index by 1.
12. If partial is empty, then
   a. Let final be "[]".
13. Else
   a. If gap is the empty String
      i. Let properties be a String formed by concatenating all the element Strings of partial with each adjacent pair of Strings separated with code unit 0x002C (the comma character). A comma is not inserted either before the first String or after the last String.
      ii. Let final be the result of concatenating "[", properties, and "]".
   b. Else
      i. Let separator be the result of concatenating code unit 0x002C (the comma character), code unit 0x000A (the line feed character), and indent.
      ii. Let properties be a String formed by concatenating all the element Strings of partial with each adjacent pair of Strings separated with separator. The separator String is not inserted either before the first String or after the last String.
      iii. Let final be the result of concatenating "[", code unit 0x000A (the line feed character), indent, properties, code unit 0x000A, stepback, and "]".
14. Remove the last element of stack.
15. Let indent be stepback.

NOTE 1 JSON structures are allowed to be nested to any depth, but they must be acyclic. If value is or contains a cyclic structure, then the stringify function must throw a TypeError exception. This is an example of a value that cannot be stringified:

```javascript
a = [];
my_text = JSON.stringify(a); // This must throw a TypeError.
```

NOTE 2 Symbolic primitive values are rendered as follows:
- The null value is rendered in JSON text as the String null.
- The undefined value is not rendered.
- The true value is rendered in JSON text as the String true.
- The false value is rendered in JSON text as the String false.

NOTE 3 String values are wrapped in double quotes. The characters " and \ are escaped with \ prefixes. Control characters are replaced with escape sequences \u000b (backspace), \f (formfeed), \n (newline), \t (carriage return), and \t (tab).
NOTE 4  Finite numbers are stringified as if by calling `ToString(number)`. NaN and Infinity regardless of sign are represented as the String `null`.

NOTE 5  Values that do not have a JSON representation (such as `undefined` and functions) do not produce a String. Instead they produce the `undefined` value. In arrays these values are represented as the String `null`. In objects an unrepresentable value causes the property to be excluded from stringification.

NOTE 6  An object is rendered as an opening left brace followed by zero or more properties, separated with commas, closed with a right brace. A property is a quoted String representing the key or property name, a colon, and then the stringified property value. An array is rendered as an opening left bracket followed by zero or more values, separated with commas, closed with a right bracket.

25 The "std:iteration" Module

The "std:iteration" module defines built-in objects that support the for-of statement and similar iteration use cases. It also defines the built-in objects that support Generator Functions.

25.1 Common Iteration Interfaces

An interface is a set of object property keys whose associated values match a specific specification. Any object that provides all the properties of an interface in conformance to the interface’s specification conforms to that interface. An interface isn’t represented by a single object and there may be many distinctively implemented objects that conform to any interface. An individual object may conform to multiple interfaces.

25.1.1 The Iteratable Interface

The `Iteratable` interface includes the following property:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>@@iterator</code></td>
<td>A zero arguments function that returns an object.</td>
<td>The function returns an object that conforms to the <code>Iterator</code> interface.</td>
</tr>
</tbody>
</table>

25.1.2 The Iterator Interface

The `Iterator` interface includes the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>next</code></td>
<td>A function that returns an object.</td>
<td>The function returns an object that conforms to the <code>Iterable</code> interface.</td>
</tr>
</tbody>
</table>

NOTE  Arguments may be passed to the next function but their interpretation and validity is dependent upon the target Iterator. Generic use of Iterators should not pass any arguments.

25.1.3 The `Iterable` Interface

The `Iterable` interface includes the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>done</code></td>
<td>Either true or false.</td>
<td>This is the result status of the an iterator <code>next</code> method call. If the end of the iterator was reached <code>done</code> is true. If the end was not reached <code>done</code> is false and a value is available.</td>
</tr>
</tbody>
</table>
### 25.2 "std:iteration" Exports

The "std:iteration" module exports the names:

- iterator
- GeneratorFunction
- Generator

### 25.3 GeneratorFunction Objects

Generator Function objects are constructor functions that are usually created by evaluating `GeneratorDeclaration`, `GeneratorExpression`, and `GeneratorMethod` syntactic productions. They may also be created by calling the `GeneratorFunction` constructor.
25.3.1 The GeneratorFunction Constructor

The GeneratorFunction constructor is the %GeneratorFunction% intrinsic object and the value of the name GeneratorFunction exported from the built-in module "std:iteration". When GeneratorFactory is called as a function rather than as a constructor, it creates and initialises a new GeneratorFactory object. Thus the function call GeneratorFunction (...) is equivalent to the object creation expression new GeneratorFunction (...) with the same arguments. However, if the this value passed in the call is an Object with an [[Internal Data]] internal data property whose value is undefined, it initialises the this value using the argument values. This permits GeneratorFunction to be used both as a factory method and to perform constructor instance initialization.

GeneratorFunction may be subclassed and subclass constructors may perform a super invocation of the GeneratorFactory constructor to initialise subclass instances. However, all syntactic forms for defining generator function objects create direct instances of GeneratorFunction. There is no syntactic means to create instances of GeneratorFunction subclasses.
25.3.1 GeneratorFunction (p1, p2, ..., pn, body)

The last argument specifies the body (executable code) of a generator function; any preceding arguments specify formal parameters.

When the `GeneratorFunction` function is called with some arguments `p1, p2, ..., pn, body` (where `n` might be 0, that is, there are no "p" arguments, and where `body` might also not be provided), the following steps are taken:

1. Let `argCount` be the total number of arguments passed to this function invocation.
2. Let `P` be the empty String.
3. If `argCount` = 0, let `bodyText` be the empty String.
4. Else if `argCount` = 1, let `bodyText` be that argument.
5. Else `argCount` > 1,
   a. Let `firstArg` be the first argument.
   b. Let `P` be `ToString(firstArg)`.
   c. ReturnIfAbrupt(`P`).
   d. Let `k` be 2.
   e. Repeat, while `k` < `argCount`
      i. Let `nextArg` be the `k`th argument.
      ii. Let `nextArgString` be `ToString(nextArg)`.
      iii. ReturnIfAbrupt(`nextArgString`).
      iv. Let `P` be the result of concatenating the previous value of `P`, the string "," (a comma), and `nextArgString`.
      v. Increase `k` by 1.
   f. Let `bodyText` be the `k`th argument.
6. Let `bodyText` be `ToString(bodyText)`.
7. ReturnIfAbrupt(`bodyText`).
8. Let `parameters` be the result of parsing `P`, interpreted as UTF-16 encoded Unicode text as described in 6.1.4, using `FormalParameters` as the goal symbol. Throw a `SyntaxError` exception if the parse fails.
9. Let `funcBody` be the result of parsing `bodyText`, interpreted as UTF-16 encoded Unicode text as described in 6.1.4, using `FunctionBody` as the goal symbol. Throw a `SyntaxError` exception if the parse fails or if any static semantics errors are detected.
10. If `funcBody Contains YieldExpression` is `false`, then throw a `SyntaxError` exception.
11. If `IsSimpleParameterList of parameters` is `false` and any element of the `BoundNames` of `parameters` also occurs in the `VarDeclaredNames of funcBody`, then throw a `SyntaxError` exception.
12. If any element of the `BoundNames of parameters` also occurs in the `LexicallyDeclaredNames of funcBody`, then throw a `SyntaxError` exception.
13. If `body Text is strict mode code (see 10.1.1)` then let `strict` be `true`, else let `strict` be `false`.
14. Let `scope` be the `Global Environment`.
15. Let `F` be the `this` value.
16. If `Type(F)` is `Object` or if `F` does not have a `[[Code]]` internal data property or if the value of `[[Code]]` is not `undefined`, then
    a. Let `F` be the result of calling `FunctionAllocate` with arguments `"Generator"` and "generator".
17. If the value of `F`'s `[[FunctionKind]]` internal data property is not "generator", then throw a `TypeError` exception.
19. Perform the `FunctionInitialise` abstract operation with arguments `F`, `Normal`, `parameters`, `body`, `scope`, and `strict`.
20. Let `prototype` be the result of the abstract operation `ObjectCreate` with the intrinsic object `%GeneratorPrototype%` as its argument.
21. Perform the abstract operation `MakeConstructor` with arguments `F`, `true`, and `prototype`.
22. Return `F`.

A `prototype` property is automatically created for every function created using the `GeneratorFunction` constructor, to provide for the possibility that the function will be used as a constructor.
25.3.1.2 new GeneratorFunction ( ... argumentsList)

When `GeneratorFunction` is called as part of a `new` expression, it creates and initialises a newly created object.

1. Let `F` be the `GeneratorFunction` function object on which the `new` operator was applied.
2. Let `argumentsList` be the `argumentsList` argument of the `[[Construct]]` internal method that was invoked by the `new` operator.
3. Return the result of `OrdinaryConstruct (F, argumentsList)`.

If `GeneratorFunction` is implemented as an ordinary function object, its `[[Construct]]` internal method will perform the above steps.

25.3.2 Properties of the GeneratorFunction Constructor

The `GeneratorFunction` constructor is a built-in Function object that inherits from the `Function` constructor. The value of the `[[Prototype]]` internal data property of the `GeneratorFunction` constructor is the intrinsic object `%Function%`.

The value of the `[[Extensible]]` internal data property of the `GeneratorFunction` constructor is `true`.

The `GeneratorFunction` constructor has the following properties:

25.3.2.1 `GeneratorFunction.length`

This is a data property with a value of 1. This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

25.3.2.2 `GeneratorFunction.prototype`

The initial value of `GeneratorFunction.prototype` is `%Generator%`, the standard built-in `GeneratorFunction` prototype.

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

25.3.2.3 `GeneratorFunction[ @@create ]()`

The `@@create` method of an object `F` performs the following steps:

1. Let `F` be the `this` value.
2. Let `proto` be the result of `GetPrototypeFromConstructor (F, "%Generator%")`.
3. ReturnIfAbrupt (proto).
4. Let `obj` be the result of calling `FunctionAllocate` with argument `proto` and "generator".
5. Return `obj`.

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

NOTE The `GeneratorFunction` `@@create` function is intentionally generic; it does not require that its `this` value be the `GeneratorFunction` constructor object. It can be transferred to other constructor functions for use as a `@@create` method. When used with other constructors, this function will create a function object whose `[[Prototype]]` value is obtained from the associated constructor.

25.3.3 Properties of the GeneratorFunction Prototype Object

The `GeneratorFunction` prototype object is an ordinary object. It is not a function object and does not have a `[[Code]]` internal data property or any other of the internal data properties listed in Table 25 or Table 39. In addition to being the value of the prototype property of the `%GeneratorFunction%` intrinsic and is itself the `%Generator%` intrinsic.
The value of the [[Prototype]] internal data property of the GeneratorFunction prototype object is the %FunctionPrototype% intrinsic object. The initial value of the [[Extensible]] internal data property of the GeneratorFunction prototype object is true.

25.3.3.1 GeneratorFunction.prototype.constructor

The initial value of GeneratorFunction.prototype.constructor is the intrinsic object %GeneratorFunction%.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

25.3.3.2 GeneratorFunction.prototype.prototype

The value of GeneratorFunction.prototype.prototype is the %GeneratorPrototype% intrinsic object.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

25.3.3.3 GeneratorFunction.prototype[@@toStringTag]

The initial value of the @@toStringTag property is the string value "GeneratorFunction".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

25.3.3.4 GeneratorFunction.prototype[@@create]( )

The @@create method of an object F performs the following steps:

1. Let F be the this value.
2. Let obj be the result of calling OrdinaryCreateFromConstructor(F, "%GeneratorPrototype%", ([[GeneratorState]], [[GeneratorContext]]) ).
3. Return obj.

This property has the attributes { [[Writable]]: true, [[Enumerable]]: false, [[Configurable]]: true }.

25.3.4 GeneratorFunction Instances

Every GeneratorFunction instance is an ordinary function object and has the internal data properties listed in Table 25. The value of the [[FunctionKind]] internal data property for all such instances is "generator".

The GeneratorFunction instances have the following own properties:

25.3.4.1 length

The value of the length property is an integer that indicates the typical number of arguments expected by the GeneratorFunction. However, the language permits the function to be invoked with some other number of arguments. The behaviour of a GeneratorFunction when invoked on a number of arguments other than the number specified by its length property depends on the function.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

25.3.4.2 prototype

Whenever a GeneratorFunction instance is created another ordinary object is also created and is the initial value of the generator function's prototype property. The value of the prototype property is used to initialise the [[Prototype]] internal data property of a newly created Generator object before the generator function object is invoked as a constructor for that newly created object.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }. 
NOTE Unlike function instances, the object that is the value of the a GeneratorFunction's prototype property does not have a constructor property whose value is the GeneratorFunction instance.

25.4 Generator Objects

A Generator object is an instance of a generator function and conforms to both the Iterator and Iterable interfaces.

Generator instances directly inherit properties from the object that is the value of the prototype property of the Generator function that created the instance. Generator instances indirectly inherit properties from the Generator Prototype intrinsic, %GeneratorPrototype%.

25.4.1 Properties of Generator Prototype

The Generator prototype object is the %GeneratorPrototype% intrinsic. It is also the initial value of the prototype property of the %Generator% intrinsic (the GeneratorFunction.prototype).

The Generator prototype is an ordinary object. It is not a Generator instance and does not have a [[Prototype]] internal data property.

The value of the [[Prototype]] internal data property of the Generator prototype object is the intrinsic object %ObjectPrototype% (19.1.4). The initial value of the [[Extensible]] internal data property of the Function prototype object is true.

All Generator instances indirectly inherit properties of the Generator prototype object.

25.4.1.1 Generator.prototype.constructor

The initial value of Generator.prototype.constructor is the intrinsic object %Generator%.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

25.4.1.2 Generator.prototype.next ( value )

The next method performs the following steps:

1. Let g be the this value.
2. Return the result of GeneratorResume(g, value).

25.4.1.3 Generator.prototype.throw ( exception )

The throw method performs the following steps:

1. Let generator be the this value.
2. If Type(generator) is not Object, then throw a TypeError exception.
3. If generator does not have a [[GeneratorState]] internal data property, then throw a TypeError exception.
4. Let state be the value of generator's [[GeneratorState]] internal data property.
5. Assert: generator also has a [[GeneratorContext]] internal data property.
6. If state is neither "suspendedStart" or "suspendedYield", then throw a TypeError exception.
7. Let E be Completion { [[type]]: throw, [[value]]: exception, [[target]]: empty }.
8. If state is "suspendedStart" then,
   a. Set generator's [[GeneratorState]] internal data property to "completed".
   b. Once a generator enters the "completed" state it never leaves it and its associated execution context is never resumed. Any execution state associated with generator can be discarded at this point.
   c. Return E.
9. Let genContext be value of generator's [[GeneratorContext]] internal data property.
10. Let methodContext be the running execution context.
12. Set generator’s [[GeneratorState]] internal data property to "executing".
13. Push genContext onto the execution context stack; genContext is now the running execution context.
14. Resume the suspended evaluation of genContext using $E$ as the result of the operation that suspended it. Let result be the value returned by the resumed computation.
15. Assert: When we return here, genContext has already been removed from the execution context stack and methodContext is the currently running execution context.
16. Return result.

25.4.1.4 Generator.prototype [@@iterator] ( )

The following steps are taken:

1. Return the this value.

25.4.1.5 Generator.prototype [@@toStringTag]

The initial value of the @@toStringTag property is the string value "Generator".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

25.4.2 Properties of Generator Instances

Generator instances are initially created with the internal data properties described in Table 39.

Table 39 — Internal Data Properties of Generator Instances

<table>
<thead>
<tr>
<th>Internal Data Property Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[GeneratorState]]</td>
<td>The current execution state of the generator. The possible values are: undefined, &quot;suspendedStart&quot;, &quot;suspendedYield&quot;, &quot;executing&quot;, and &quot;completed&quot;.</td>
</tr>
<tr>
<td>[[GeneratorContext]]</td>
<td>The execution context that is used when executing the code of this generator.</td>
</tr>
</tbody>
</table>

25.4.3 Iteration Related Abstract Operations

25.4.3.1 GeneratorStart (generator, generatorBody)

1. Assert: The value of generator’s [[GeneratorState]] internal data property is undefined.
2. Let genContext be the running execution context.
3. Set the Generator component of genContext to generator.
4. Set the code evaluation state of genContext such that when evaluation is resumed for that execution context the following steps will be performed:
   a. Let result be the result of evaluating generatorBody.
   b. Assert: if we return here, the generator either threw an exception or performed an implicit or explicit return.
   c. Remove genContext from the execution context stack and restore the execution context that is at the top of the execution context stack as the running execution context.
   d. Set generator’s [[GeneratorState]] internal data property to "completed".
   e. Once a generator enters the "completed" state it never leaves it and its associated execution context is never resumed. Any execution state associated with generator can be discard at this point.
   f. ReturnIfAbrupt(result).
   g. Return CreateIterResultObject(result, true).
5. Set generator’s [[GeneratorContext]] internal data property to genContext.
6. Set generator’s [[GeneratorState]] internal data property to "suspendedStart".
7. Return NormalCompletion(generator).
25.4.3.2 GeneratorResume ( generator, value )

The abstract operation GeneratorResume with arguments generator and value performs the following steps:

1. If Type(generator) is not Object, then throw a TypeError exception.
2. If generator does not have a [[GeneratorState]] internal data property, then throw a TypeError exception.
3. Let state be the value of generator's [[GeneratorState]] internal data property.
4. Assert: generator also has a [[GeneratorContext]] internal data property.
5. If state is neither "suspendedStart" or "suspendedYield", then throw a TypeError exception.
6. If state is "suspendedStart" and value is not undefined, then throw a TypeError exception.
7. Let genContext be value of generator's [[GeneratorContext]] internal data property.
8. Let methodContext be the running execution context.
10. Let generator's [[GeneratorState]] internal data property to "executing".
11. Push genContext onto the execution context stack; genContext is now the running execution context.
12. Resolve the suspended evaluation of genContext using NormalCompletion(value) as the result of the operation that suspended it. Let result be the value returned by the resumed computation.
13. Assert: When we return here, genContext has already been removed from the execution context stack and methodContext is the currently running execution context.
14. Return result.

25.4.3.3 GeneratorYield ( itrNextObj )

The abstract operation GeneratorYield with argument itrNextObj performs the following steps:

1. Assert: itrNextObj is an Object that implemented the ItrResult interface.
2. Let genContext be the running execution context.
3. Assert: genContext is the execution context of a generator.
4. Let generator be the value of the Generator component of genContext.
5. Set the value of generator's [[GeneratorState]] internal data property to "suspendedYield".
6. Remove genContext from the execution context stack and restore the execution context that is at the top of the execution context stack as the running execution context.
7. Set the code evaluation state of genContext such that when evaluation is resumed with a Completion resumptionValue the following steps will be performed:
   a. Return resumptionValue.
   b. NOTE: This results to the evaluation of the YieldExpression production that originally called this abstract operation.
8. Resume the suspended evaluation of (genContext using NormalCompletion(value) as the result of the operation that suspended it. Let result be the value returned by the resumed computation.
9. Assert: When we return here, genContext has already been removed from the execution context stack and the currently running execution context is the context that most recently resumed execution of generator.
10. Return NormalCompletion(itrNextObj).
11. NOTE: This returns to the evaluation of the operation that had most previously resumed evaluation of genContext.

25.4.3.4 CreateItrResultObject ( value, done )

The abstract operation CreateItrResultObject with arguments value and done creates an object that supports the ItrResult interface by performing the following steps:

1. Assert: Type(done) is Boolean.
2. Let obj be the result of performing ObjectCreate(%ObjectPrototype%).
3. Perform CreateOwnProperty(obj, "value", value).
4. Perform CreateOwnProperty(obj, "done", done).
5. Return obj.

25.4.3.5 GetIterator ( obj )

The abstract operation GetIterator with argument obj performs the following steps:

1. Let iterator be the result of performing Invoke with arguments obj, @@iterator and an empty List.
2. ReturnIfAbrupt(iterator).
3. If Type(iterator) is not Object, then throw a TypeError exception.
4. Return iterator.

25.4.3.6 IteratorNext (iterator, value)
The abstract operation IteratorNext with argument iterator and optional argument value performs the following steps:

1. If value was not passed, let value be undefined.
2. Let result be the result of Invoke(iterator, "next", (value)).
3. ReturnIfAbrupt(result).
4. If Type(result) is not Object, then throw a TypeError exception.
5. Return result.

25.4.3.7 IteratorComplete (itrResult)
The abstract operation IteratorComplete with argument itrResult performs the following steps:

1. Assert: Type(itrResult) is Object.
2. Let done be the result of Get(itrResult, "done").
3. Return ToBoolean(done).

25.4.3.8 IteratorValue (itrResult)
The abstract operation IteratorValue with argument itrResult performing the following steps:

1. Assert: Type(itrResult) is Object.
2. Return the result of Get(itrResult, "value").

25.4.3.9 CreateEmptyIterator ()
The abstract operation CreateEmptyIterator with no arguments creates an Iterator object whose next method always reports that the iterator is done. It performs the following steps:

1. Let obj be the result of performing ObjectCreate(%ObjectPrototype%).
2. Let emptyNextMethod be the result of CreateBuiltinFunction using the steps defined below.
3. Perform CreateOwnDataProperty(obj, "next", emptyNextMethod).
4. Return obj.

An emptyNextMethod method performs the following steps:

1. Let result be the result of performing CreateItResultObject (undefined, true).
2. Return result.

26 The Reflect Module

26.1 Exported Function Properties Reflecting the Essential Internal Methods

26.1.1 Reflect.defineProperty(target, propertyKey, attributes)

When the defineProperty function is called with arguments target, propertyKey, and attributes the following steps are taken:

1. Let obj be ToObject(target).
2. ReturnIfAbrupt(obj).
3. Let key be ToPropertyKey(propertyKey).
4. ReturnIfAbrupt(key).
5. Let desc be the result of calling ToPropertyDescriptor with attributes as the argument.
6. ReturnIfAbrupt(desc).
7. Return the result of calling the [[DefineOwnProperty]] internal method of obj with arguments key and desc.

26.1.2 Reflect.deleteProperty (target, propertyKey)

When the deleteProperty function is called with arguments target and propertyKey, the following steps are taken:

1. Let obj be ToObject(target).
2. ReturnIfAbrupt(obj).
3. Let key be ToPropertyKey(propertyKey).
4. ReturnIfAbrupt(key).
5. Return the result of calling the [[Delete]] internal method of obj with argument key.

26.1.3 Reflect.enumerate (target)

When the enumerate function is called with argument target the following steps are taken:

1. Let obj be ToObject(target).
2. ReturnIfAbrupt(obj).
3. Let iterator be the result of calling the [[Enumerate]] internal method of obj.
4. Return iterator.

26.1.4 Reflect.get (target, propertyKey, receiver=target)

When the get function is called with arguments target, propertyKey, and receiver the following steps are taken:

1. Let obj be ToObject(target).
2. ReturnIfAbrupt(obj).
3. Let key be ToPropertyKey(propertyKey).
4. ReturnIfAbrupt(key).
5. If receiver is not present, then
   a. Let receiver be target.
6. Return the result of calling the [[Get]] internal method of obj with arguments key, and receiver.

26.1.5 Reflect.getOwnPropertyDescriptor (target, propertyKey)

When the getOwnPropertyDescriptor function is called with arguments target and propertyKey, the following steps are taken:

1. Let obj be ToObject(target).
2. ReturnIfAbrupt(obj).
3. Let key be ToPropertyKey(propertyKey).
4. ReturnIfAbrupt(key).
5. Let desc be the result of calling the [[GetOwnProperty]] internal method of obj with argument key.
6. ReturnIfAbrupt(desc).
7. Return the result of calling FromPropertyDescriptor(desc).

26.1.6 Reflect.getPrototypeOf (target)

When the getPrototypeOf function is called with argument target the following steps are taken:

1. Let obj be ToObject(target).
2. ReturnIfAbrupt(obj).
3. Return the result of calling the [[GetInheritance]] internal method of obj.

26.1.7 Reflect.has (target, propertyKey)

When the hasOwnProperty function is called with arguments target and propertyKey, the following steps are taken:
1. Let \( \text{obj} \) be \( \text{ToObject}(\text{target}) \).
2. ReturnIfAbrupt(\( \text{obj} \)).
3. Let \( \text{key} \) be \( \text{ToPropertyKey}(\text{propertyKey}) \).
4. ReturnIfAbrupt(\( \text{key} \)).
5. Return the result of calling the \([\text{HasProperty}]\) internal method of \( \text{obj} \) with argument \( \text{key} \).

26.1.8 Reflect.hasOwn (target, propertyKey)

When the \( \text{hasOwn} \) function is called with arguments \( \text{target} \) and \( \text{propertyKey} \), the following steps are taken:

1. Let \( \text{obj} \) be \( \text{ToObject}(\text{target}) \).
2. ReturnIfAbrupt(\( \text{obj} \)).
3. Let \( \text{key} \) be \( \text{ToPropertyKey}(\text{propertyKey}) \).
4. ReturnIfAbrupt(\( \text{key} \)).
5. Return the result of calling the \([\text{HasOwnProperty}]\) internal method of \( \text{obj} \) with argument \( \text{key} \).

26.1.9 Reflect.isExtensible (target)

When the \( \text{isExtensible} \) function is called with argument \( \text{target} \) the following steps are taken:

1. Let \( \text{obj} \) be \( \text{ToObject}(\text{target}) \).
2. ReturnIfAbrupt(\( \text{obj} \)).
3. Return the result of calling the \([\text{IsExtensible}]\) internal method of \( \text{obj} \).

26.1.10 Reflect.invoke (target, propertyKey, argumentsList, receiver=\text{target})

When the \( \text{invoke} \) function is called with arguments \( \text{target}, \text{propertyKey}, \text{argumentsList} \), and \( \text{receiver} \) the following steps are taken:

1. Let \( \text{obj} \) be \( \text{ToObject}(\text{target}) \).
2. ReturnIfAbrupt(\( \text{obj} \)).
3. Let \( \text{key} \) be \( \text{ToPropertyKey}(\text{propertyKey}) \).
4. ReturnIfAbrupt(\( \text{key} \)).
5. If \( \text{receiver} \) is not present, then
   a. Let \( \text{receiver} \) be \( \text{target} \).
6. Let \( \text{argList} \) be the result of \( \text{CreateListFromArrayLike}(\text{argumentsList}) \).
7. ReturnIfAbrupt(\( \text{argList} \)).
8. Return the result of calling the \([\text{Invoke}]\) internal method of \( \text{obj} \) with arguments \( \text{key} \), \( \text{argList} \), and \( \text{receiver} \).

26.1.11 Reflect.ownKeys (target)

When the \( \text{ownKeys} \) function is called with argument \( \text{target} \) the following steps are taken:

1. Let \( \text{obj} \) be \( \text{ToObject}(\text{target}) \).
2. ReturnIfAbrupt(\( \text{obj} \)).
3. Let \( \text{keys} \) be the result of calling the \([\text{OwnPropertyKeys}]\) internal method of \( \text{obj} \).

26.1.12 Reflect.preventExtensions (target)

When the \( \text{preventExtensions} \) function is called with argument \( \text{target} \), the following steps are taken:

1. Let \( \text{obj} \) be \( \text{ToObject}(\text{target}) \).
2. ReturnIfAbrupt(\( \text{obj} \)).
3. Return the result of calling the \([\text{PreventExtensions}]\) internal method of \( \text{obj} \).

26.1.13 Reflect.set (target, propertyKey, V, receiver=\text{target})

When the \( \text{set} \) function is called with arguments \( \text{target}, \text{propertyKey}, \text{V}, \text{receiver} \) the following steps are taken:
1. Let obj be ToObject(target).
2. ReturnIfAbrupt(obj).
3. Let key be ToPropertyKey(propertyKey).
4. ReturnIfAbrupt(key).
5. If receiver is not present, then
   a. Let receiver be target.
6. Return the result of calling the [[Set]] internal method of obj with arguments key, V, and receiver.

26.1.14 Reflect.setPrototypeOf(target, proto)

When the setPrototypeOf function is called with arguments target and propertyKey, the following steps are taken:

1. Let obj be ToObject(target).
2. ReturnIfAbrupt(obj).
3. If Type(proto) is not Object and proto is not null, then throw a TypeError exception.
4. Return the result of calling the [[SetInheritance]] internal method of obj with argument proto.

26.2 Proxy Objects
Annex A
(informative)

Grammar Summary

TODO: The Grammars in the Annex have not yet been updated for ES6. For now, see the grammars in the main body of the specification.

A.1 Lexical Grammar

SourceCharacter ::
    any Unicode code unit

InputElementDiv ::
    See clause 7
    WhiteSpace
    LineTerminator
    Comment
    Token
    DivPunctuator

InputElementRegExp ::
    See clause 7
    WhiteSpace
    LineTerminator
    Comment
    Token
    RegularExpressionLiteral

WhiteSpace ::
    See 7.2
    <TAB>
    <VT>
    <FF>
    <SP>
    <NBSP>
    <BOM>
    <USP>

LineTerminator ::
    See 7.3
    <LF>
    <CR>
    <LS>
    <PS>
LineTerminatorSequence ::
  <LF>
  <CR> [lookahead ≠ <LF>]  
  <LS>
  <PS>
  <CR> <LF>

Comment ::
  MultiLineComment
  SingleLineComment

MultiLineComment ::
  /* MultiLineCommentChars*/

MultiLineCommentChars ::
  MultiLineNotAsteriskChar MultiLineCommentCharsopt
  * PostAsteriskCommentCharsopt

PostAsteriskCommentChars ::
  MultiLineNotForwardSlashOrAsteriskChar MultiLineCommentCharsopt
  * PostAsteriskCommentCharsopt

MultiLineNotAsteriskChar ::
  SourceCharacter but not *

MultiLineNotForwardSlashOrAsteriskChar ::
  SourceCharacter but not one of / or *

SingleLineComment ::
  // SingleLineCommentChars

SingleLineCommentChars ::
  SingleLineCommentChar SingleLineCommentCharsopt

SingleLineCommentChar ::
  SourceCharacter but not LineTerminator

Token ::
  IdentifierName
  Punctuator
  NumericLiteral
  StringLiteral

Identifier ::
  IdentifierName but not ReservedWord

IdentifierName ::
  IdentifierStart
  IdentifierName IdentifierPart
IdentifierStart ::
    UnicodeLetter
    $
    \backslash$ UnicodeEscapeSequence

IdentifierPart ::
    IdentifierStart
    UnicodeCombiningMark
    UnicodeDigit
    UnicodeConnectorPunctuation
    <ZWNJ>
    <ZWJ>

UnicodeLetter ::
    any character in the Unicode categories "Uppercase letter (Lu)", "Lowercase letter (Ll)", "Titlecase letter (Lt)", "Modifier letter (Lm)", "Other letter (Lo)", or "Letter number (Nl)".

UnicodeCombiningMark ::
    any character in the Unicode categories "Non-spacing mark (Mn)", or "Combining spacing mark (Mc)"

UnicodeDigit ::
    any character in the Unicode category "Decimal number (Nd)"

UnicodeConnectorPunctuation ::
    any character in the Unicode category "Connector punctuation (Pc)"

ReservedWord ::
    Keyword
    FutureReservedWord
    NullLiteral
    BooleanLiteral

Keyword ::

Annex B
(normative)

Additional ECMAScript Features for Web Browsers

The ECMAScript language syntax and semantics defined in this annex are required when the ECMAScript host is a web browser. The content of this annex is normative but optional if the ECMAScript host is not a web browser.

B.1 Additional Syntax

B.1.1 Numeric Literals

The syntax and semantics of 11.8.3 is extended as follows except that this extension is not allowed for strict mode code:

Syntax

NumericLiteral ::
  DecimalLiteral
  BinaryIntegerLiteral
  OctalIntegerLiteral
  HexIntegerLiteral
  LegacyOctalIntegerLiteral

LegacyOctalIntegerLiteral ::
  0 OctalDigit
  LegacyOctalIntegerLiteral OctalDigit

Static Semantics

- The MV of LegacyOctalIntegerLiteral :: 0 OctalDigit is the MV of OctalDigit.
- The MV of LegacyOctalIntegerLiteral :: LegacyOctalIntegerLiteral OctalDigit is (the MV of LegacyOctalIntegerLiteral times 8) plus the MV of OctalDigit.

B.1.2 String Literals

The syntax and semantics of 11.8.4 is extended as follows except that this extension is not allowed for strict mode code:

Syntax

EscapeSequence ::
  CharacterEscapeSequence
  OctalEscapeSequence
  HexEscapeSequence
  UnicodeEscapeSequence

OctalEscapeSequence ::
  OctalDigit [lookahead = DecimalDigit]
  ZeroToThree OctalDigit [lookahead = DecimalDigit]
  FourToSeven OctalDigit
  ZeroToThree OctalDigit OctalDigit

ZeroToThree :: one of
  0 1 2 3
Static Semantics

- The CV of OctalEscapeSequence :: OctalDigit [lookahead = DecimalDigit] is the character whose code unit value is the MV of the OctalDigit.
- The CV of OctalEscapeSequence :: FourToSeven OctalDigit [lookahead = DecimalDigit] is the character whose code unit value is (8 times the MV of the ZeroToThree) plus the MV of the OctalDigit.
- The CV of OctalEscapeSequence :: FourToSeven OctalDigit OctalDigit is the character whose code unit value is (8 times the MV of the ZeroToThree) plus (8 times the MV of the first OctalDigit) plus the MV of the second OctalDigit.
- The MV of ZeroToThree :: 0 is 0.
- The MV of ZeroToThree :: 1 is 1.
- The MV of ZeroToThree :: 2 is 2.
- The MV of ZeroToThree :: 3 is 3.
- The MV of FourToSeven :: 4 is 4.
- The MV of FourToSeven :: 5 is 5.
- The MV of FourToSeven :: 6 is 6.
- The MV of FourToSeven :: 7 is 7.

B.1.3 HTML-like Comments

TODO See http://javascript.spec.whatwg.org/#comment-syntax

B.2 Additional Properties

When the ECMAScript host is a web browser the following additional properties of the standard built-in objects are defined.

B.2.1 Additional Properties of the Global Object

B.2.1.1 escape (string)

The escape function is a property of the global object. It computes a new version of a String value in which certain characters have been replaced by a hexadecimal escape sequence.

For those characters being replaced whose code unit value is \0xFF or less, a two-digit escape sequence of the form `%xx` is used. For those characters being replaced whose code unit value is greater than \0xFF, a four-digit escape sequence of the form `%uxxxx` is used.

When the escape function is called with one argument `string`, the following steps are taken:

1. Let `string` be `ToString(string).
2. ReturnIfAbrupt(string).
3. Let `length` be the number of code units in `string`.
4. Let `R` be the empty string.
5. Let `k` be 0.
6. Repeat, while `k < length`:
   a. Let `char` be the code unit (represented as a 16-bit unsigned integer) at position `k` within `string`.
   b. If `char` is the code point of one of the 69 nonblank characters
      "ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz0123456789@*_+-./" then
      i. Let `S` be a String containing the single character `char`.

c. Else if char > 256,
   i. Let S be a String containing six characters “%uwxyz” where wxyz are four hexadecimal digits encoding the value of char.

d. Else, char < 256
   i. Let S be a String containing three characters “%xy” where xy are two hexadecimal digits encoding the value of char.

e. Let R be a new String value computed by concatenating the previous value of R and S.

f. Increase k by 1.

7. Return R.

NOTE The encoding is partly based on the encoding described in RFC 1738, but the entire encoding specified in this standard is described above without regard to the contents of RFC 1738. This encoding does not reflect changes to RFC 1738 made by RFC 3986.

B.2.1.2 unescape (string)

The unescape function is a property of the global object. It computes a new version of a String value in which each escape sequence of the sort that might be introduced by the escape function is replaced with the character that it represents.

When the unescape function is called with one argument string, the following steps are taken:

1. Let string be ToString(string).
2. ReturnIfAbrupt(string).
3. Let length be the number of code units in string.
4. Let R be the empty String.
5. Let k be 0.
6. Repeat, while k ≠ length
   a. Let c be the code unit at position k within string.
      b. If c is %,
         i. If k ≤ length-6 and the code unit at position k+1 within string is u and the four code units at positions k+2, k+3, k+4, and k+5 within string are all hexadecimal digits, then
            1. Let c be the code unit whose value is the integer represented by the four hexadecimal digits at positions k+2, k+3, k+4, and k+5 within string.
            2. Increase k by 5.
         ii. Else if k ≤ length-3 and the two code units at positions k+1 and k+2 within string are both hexadecimal digits, then
             1. Let c be the code unit whose value is the integer represented by two zeroes plus the two hexadecimal digits at positions k+1 and k+2 within string.
             2. Increase k by 2.
      c. Let R be a new String value computed by concatenating the previous value of R and c.
      d. Increase k by 1.
7. Return R.

B.2.2 Additional Properties of the Object.prototype Object

B.2.2.1 Object.prototype.__proto__

Object.prototype.__proto__ is an accessor property with attributes { [[Enumerable]]: false, [[Configurable]]: true }. The [[Get]] and [[Set]] attributes are defined as follows

B.2.2.1.1 get Object.prototype.__proto__

The value of the [[Get]] attribute is a built-in function that requires no arguments. It performs the following steps:

1. Let O be the result of calling ToObject passing the this value as the argument.
2. ReturnIfAbrupt(O).
3. Return the result of calling the [[GetInheritance]] internal method of O.
B.2.2.1.2 set Object.prototype.__proto__

The value of the [[Set]] attribute is a built-in function that takes an argument proto. It performs the following steps:

1. Let O be CheckObjectCoercible(this value).
2. ReturnIfAbrupt(O). If Type(proto) is neither Object or Null, then return proto.
3. If Type(O) is not Object, then return proto.
4. Let status be the result of calling the [[SetInheritance]] internal method of O with argument proto.
5. ReturnIfAbrupt(status).
6. If status is false, then throw a TypeError exception.
7. Return proto.

B.2.3 Additional Properties of the String.prototype Object

B.2.3.1 String.prototype.substr (start, length)

The substr method takes two arguments, start and length, and returns a substring of the result of converting the this object to a String, starting from character position start and running for length characters (or through the end of the String if length is undefined). If start is negative, it is treated as (sourceLength + start) where sourceLength is the length of the String. The result is a String value, not a String object. The following steps are taken:

1. Let O be CheckObjectCoercible(this value).
2. Let S be ToString(O).
3. Let intStart be ToInteger(start).
4. ReturnIfAbrupt(intStart).
5. If length is undefined, let end be +∞, otherwise let end be ToInteger(length).
6. ReturnIfAbrupt(end).
7. Let size be the number of characters in S.
8. If intStart is negative, then let intStart be max(size + intStart,0).
9. Let resultLength be min(max(end, size – intStart),0).
10. If resultLength ≤ 0, return the empty String "".
11. Return a String containing resultLength consecutive characters from S beginning with the character at position intStart.

The length property of the substr method is 2.

NOTE The substr function is intentionally generic; it does not require that its this value be a String object. Therefore it can be transferred to other kinds of objects for use as a method.

B.2.3.2 String.prototype.anchor (name)

When the anchor method is called with argument name, the following steps are taken:

1. Let S be the this value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, "a", "name" and name.

The abstract operation CreateHTML is called with arguments string, tag, attribute, and value. The arguments tag and attribute must be string values. The following steps are taken:

1. Let str be CheckObjectCoercible(string).
2. Let S be ToString(str).
3. ReturnIfAbrupt(S).
4. Let p/f be the string value that is the concatenation of "<" and tag.
5. If attribute is not the empty String, then
   a. Let V be the result of performing ToString(value).
   b. ReturnIfAbrupt(V).
c. Let escapedV be the string value that is the same as V except that each occurrence of the character " (code unit value 0x0022) in V has been replaced with the six character sequence "&quot;.
d. Let p1 be the string value that is the concatenation of the following string values:
   • p1
   • a single space code unit 0x0020
   • attribute
   • "="
   • escapedV
   • "".

6. Let p2 be the string value that is the concatenation of p1 and ">".
7. Let p3 be the string value that is the concatenation of p2 and S.
8. Let p4 be the string value that is the concatenation of p2, "<f", tag, and ">".

B.2.3.3 String.prototype.big ()
When the big method is called with no arguments, the following steps are taken:

1. Let S be the this value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, "big", "" and "".

B.2.3.4 String.prototype.blink ()
When the blink method is called with no arguments, the following steps are taken:

1. Let S be the this value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, "blink", "" and "".

B.2.3.5 String.prototype.bold ()
When the bold method is called with no arguments, the following steps are taken:

1. Let S be the this value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, "b", "" and "".

B.2.3.6 String.prototype.fixed ()
When the fixed method is called with no arguments, the following steps are taken:

1. Let S be the this value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, "tt", "" and "".

B.2.3.7 String.prototype.fontcolor ( color )
When the fontcolor method is called with argument color, the following steps are taken:

1. Let S be the this value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, "font", "color" and color.

B.2.3.8 String.prototype.fontsize ( size )
When the fontsize method is called with argument size, the following steps are taken:

1. Let S be the this value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, \texttt{"font"}, \texttt{"size"} and \texttt{size}.

\textbf{B.2.3.9} \texttt{String.prototype.italics()}  
When the \texttt{italics} method is called with no arguments, the following steps are taken:

1. Let S be the \texttt{this} value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, \texttt{"i"}, \texttt{""} and \texttt{""}.

\textbf{B.2.3.10} \texttt{String.prototype.link(url)}  
When the \texttt{link} method is called with argument \texttt{url}, the following steps are taken:

1. Let S be the \texttt{this} value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, \texttt{"a"}, \texttt{"href"} and \texttt{url}.

\textbf{B.2.3.11} \texttt{String.prototype.small()}  
When the \texttt{small} method is called with no arguments, the following steps are taken:

1. Let S be the \texttt{this} value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, \texttt{"small"}, \texttt{""} and \texttt{""}.

\textbf{B.2.3.12} \texttt{String.prototype.strike()}  
When the \texttt{strike} method is called with no arguments, the following steps are taken:

1. Let S be the \texttt{this} value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, \texttt{"strike"}, \texttt{""} and \texttt{""}.

\textbf{B.2.3.13} \texttt{String.prototype.sub()}  
When the \texttt{sub} method is called with no arguments, the following steps are taken:

1. Let S be the \texttt{this} value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, \texttt{"sub"}, \texttt{""} and \texttt{""}.

\textbf{B.2.3.14} \texttt{String.prototype.sup()}  
When the \texttt{sup} method is called with no arguments, the following steps are taken:

1. Let S be the \texttt{this} value.
2. Return the result of performing the abstract operation CreateHTML with arguments S, \texttt{"sup"}, \texttt{""} and \texttt{""}.

\textbf{B.2.4} Additional Properties of the Date.prototype Object

\textbf{B.2.4.1} \texttt{Date.prototype.getFullYear()}  
\texttt{NOTE} The \texttt{getFullYear} method is preferred for nearly all purposes, because it avoids the \texttt{"year 2000 problem."}  
When the \texttt{getFullYear} method is called with no arguments, the following steps are taken:

1. Let \texttt{t} be this time value.
2. ReturnIfAbrupt(\texttt{t}).
3. If \texttt{t} is \texttt{NaN}, return \texttt{NaN}.  

© Ecma International 2013
4. Return YearFromTime(LocalTime(t)) − 1900.

B.2.4.2 Date.prototype.setYear (year)

NOTE The setFullYear method is preferred for nearly all purposes, because it avoids the “year 2000 problem.”

When the setYear method is called with one argument year, the following steps are taken:

1. Let t be the result of LocalTime(this time value); but if this time value is NaN, let t be +0.
2. Let y be ToNumber(year).
3. If y is NaN, set the [[DateValue]] internal data property of this Date object to NaN and return NaN.
4. If y is not NaN and 0 ≤ ToInteger(y) ≤ 99 then let yyyy be ToInteger(y) + 1900. Otherwise, let yyyy be y.
5. Let d be MakeDay(yyyy, MonthFromTime(t), DateFromTime(t)).
6. Let date be UTC(MakeDate(d, TimeWithinDay(t))).
7. Set the [[DateValue]] internal data property of this Date object to TimeClip(date).
8. Return the value of the [[DateValue]] internal data property of this Date object.

B.2.4.3 Date.prototype.toGMTString ( )

NOTE The property toUTCString is preferred. The toGMTString property is provided principally for compatibility with old code. It is recommended that the toUTCString property be used in new ECMAScript code.

The Function object that is the initial value of Date.prototype.toGMTString is the same Function object that is the initial value of Date.prototype.toUTCString.

B.2.5 Additional Properties of the RegExp.prototype Object

B.2.5.1 RegExp.prototype.compile (pattern, flags)

When the compile method is called with arguments pattern and flags, the following steps are taken:

1. Let O be the this value.
2. If Type(O) is not Object or Type(O) is Object and O does not have a [[RegExpMatcher]] internal data property, then
   a. Throw a TypeError exception.
3. Let extensible be the result of calling the [[IsExtensible]] internal method of O.
4. If extensible is false, then throw a TypeError exception.
5. If Type(pattern) is Object and pattern has a [[RegExpMatcher]] internal data property, then
   a. If the value of pattern’s [[RegExpMatcher]] internal data property is undefined, then throw a TypeError exception.
   b. If flags is not undefined, then throw a TypeError exception.
   c. Let P be the value of pattern’s [[OriginalSource]] internal data property.
   d. Let F be the value of pattern’s [[OriginalFlags]] internal data property.
6. Else,
   a. let P be pattern.
   b. let F be flags.
7. Return the result of the abstract operation RegExpInitialise with arguments O, P, and F.

NOTE The compile method completely reinitialised the this object RegExp with a new pattern and flags. An implementation may interpret use of this method as an assertion that the resulting RegExp object will be used multiple times and hence is a candidate for extra optimization.

B.3 Other Additional Features

B.3.1 __proto___ Property Names in Object Initialisers

In 12.1.5 the Property Definition Evaluation algorithm for the production PropertyDefinition : PropertyName : AssignmentExpression is replaced with the following:
PropertyDefinition : PropertyName : AssignmentExpression

1. Let propKey be the result of evaluating PropertyName.
2. ReturnIfAbrupt(propKey).
3. Let exprValue be the result of evaluating AssignmentExpression.
4. Let propValue be GetValue(exprValue).
5. ReturnIfAbrupt(propValue).
6. If propKey is the string value "__proto__" and if isComputedPropertyName(propKey) is false, then
   a. If Type(v) is either Object or Null, then
      i. Return the result of calling the [[SetInheritance]] internal method of object with argument propValue.
   b. Return NormalCompletion empty.
7. If the source code corresponding to PropertyDefinition is strict code and if isComputedPropertyName(propKey) is true, then
   a. Let duplicateKey be the result of calling the [[HasOwnProperty]] internal method of object with argument propKey.
   b. ReturnIfAbrupt(duplicateKey).
   c. If duplicateKey is true, then throw a TypeErro exception.
8. Let desc be the Property Descriptor [[Value]]; propValue, [[Writable]]; true, [[Enumerable]]; true, [[Configurable]]; true.
9. Return the result of DefinePropertyOrThrow(object, propKey, desc).

B.3.2 Web Legacy Compatibility for Block-Level Function Declarations

Prior to the Sixth Edition, the ECMAScript specification did not define the occurrence of a FunctionDeclaration as an element of a Block statement's StatementList. However, support for that form of FunctionDeclaration was an allowable extension and most browser-hosted ECMAScript implementations permitted them. However, the semantics of such declarations differ among those implementations. Because of these semantic differences, existing web ECMAScript code that uses Block-level function declarations is only portable among browser implementations if the usage only depends upon the semantic intersection of all of the browser implementations for such declarations. The following are the use cases that fall within that intersection semantics:

1. A function is declared and only referenced within a single block
   • A function declaration with the name f is declared exactly once within the function code of an enclosing function g and that declaration is nested within a Block.
   • No other declaration of f that is not a var declaration occurs within the function code of g
   • All references to f occur within the StatementList of the Block containing the declaration of f.

2. A function is declared and possibly used within a single Block but also referenced by an inner function definition that is not contained within that same Block.
   • A function declaration with the name f is declared exactly once within the function code of an enclosing function g and that declaration is nested within a Block.
   • No other declaration of f that is not a var declaration occurs within the function code of g
   • References to f may occur within the StatementList of the Block containing the declaration of f.
   • References to f occur within the function code of g that lexically follows the Block containing the declaration of f.

3. A function is declared and possibly used within a single block but also referenced within subsequent blocks.
   • A function declaration with the name f is declared exactly once within the function code of an enclosing function g and that declaration is nested within a Block.
   • No other declaration of f that is not a var declaration occurs within the function code of g
   • References to f may occur within the StatementList of the Block containing the declaration of f.
   • References to f occur within another function h that is nested within g and no other declaration of f shadows the references to f from within h.
   • All invocations of f occur after the declaration of f has been evaluated.
The first use case is interoperable with the inclusion of Block level function declarations in the sixth edition. Any pre-existing ECMAScript code that employs use case will operate using the Block level function declarations semantics defined by clauses 10 and 13 of this specification.

Sixth edition interoperability for the second and third use cases requires the following extensions to the clauses 10 and 14 semantics. These extensions are applied to a non-strict mode functions $g$ if the above pre-conditions of use cases 2 and 3 above exist at the time of static semantic analysis of $g$. However, the last pre-condition of use case 3 is not included in this determination and the determination is not applied to any function declaration that is nested within syntactic constructs that are specified in the Fifth edition of this specification.

1. Let $B$ be environment record for the construct within $g$ that introduces a new environment contour and which most closely encloses the declaration of $f$, all function code references to $f$, and the definitions of all nested functions that contain unshadowed references to $f$. This syntactic construct may be the definition of $g$ itself, in which case $B$ is the function environment record for $g$.

2. As part of the instantiation of $B$, its CreateMutableBinding concrete method is called with arguments "f" (the string name of the function) and false. This creates an uninitialised binding for the name $f$. Any reference that resolves to that binding prior to step 3 below will throw a ReferenceError exception.

3. When the InitialiseBinding concrete method is used to initialise the binding for the function declaration $f$ also invoke InitialiseBind on $B$ using the same arguments.

If an ECMAScript implication has a mechanism that produces diagnostic warning messages, a warning should be produced for each function $g$ for which the above steps are performed.
The Strict Mode of ECMAScript

The strict mode restriction and exceptions

- The identifiers "implements", "interface", "let", "package", "private", "protected", "public", "static", and "yield" are classified as FutureReservedWord tokens within strict mode code. (11.6.1.2).
- A conforming implementation, when processing strict mode code, may not extend the syntax of NumericLiteral (11.8.3) to include LegacyOctalIntegerLiteral as described in B.1.1.
- A conforming implementation, when processing strict mode code (see 10.1.1), may not extend the syntax of EscapeSequence to include LegacyOctalEscapeSequence as described in B.1.2.
- Assignment to an undeclared identifier or otherwise unresolvable reference does not create a property in the global object. When a simple assignment occurs within strict mode code, its LeftHandSide must not evaluate to an unresolvable Reference. If it does a ReferenceError exception is thrown (6.2.4.2). The LeftHandSide also may not be a reference to a data property with the attribute value {[[Writable]]: false}, to an accessor property with the attribute value {[[Set]]: undefined}, nor to a non-existent property of an object whose [[Extensible]] internal data property has the value false. In these cases a TypeError exception is thrown (12.13).
- The identifier eval or arguments may not appear as the LeftHandSideExpression of an Assignment operator (12.13) or of a PostfixExpression (12.13) or as the UnaryExpression operated upon by a Prefix Increment (12.4.4) or a Prefix Decrement (12.4.5) operator.
- Arguments objects for strict mode functions define non-configurable accessor properties named "caller" and "callee" which throw a TypeError exception on access (9.1.16.9).
- Arguments objects for strict mode functions do not dynamically share their array indexed property values with the corresponding formal parameter bindings of their functions. (9.2.5.1).
- For strict mode functions, if an arguments object is created the binding of the local identifier arguments to the arguments object is immutable and hence may not be the target of an assignment expression (9.1.16.11).
- It is a SyntaxError if strict mode code contains an ObjectLiteral with more than one definition of any data property (12.1.5).
- It is a SyntaxError if the Identifier "eval" or the Identifier "arguments" occurs as the Identifier in a PropertySetParameterList of a PropertyDefinition that is contained in strict code or if its FunctionBody is strict code (12.1.5).
- Strict mode eval code cannot instantiate variables or functions in the variable environment of the caller to eval, instead, a new variable environment is created and that environment is used for declaration binding instantiation for the eval code (18.2.1).
- If this is evaluated within strict mode code, then the this value is not coerced to an object. A this value of null or undefined is not converted to the global object and primitive values are not converted to wrapper objects. The this value passed via a function call (including calls made using Function.prototype.apply and Function.prototype.call) do not coerce the passed this value to an object (8.3.2, 12.1.1, 19.2.3.3, 19.2.3.1).
- When a delete operator occurs within strict mode code, a SyntaxError is thrown if its UnaryExpression is a direct reference to a variable, function argument, or function name (11.4.1).

Commented [AWB18200]: This entire section needs to be updated to include strict mode restrictions that apply to new ES6 features.
• When a delete operator occurs within strict mode code, a TypeError is thrown if the property to be deleted has the attribute { [[Configurable]]: false } (12.4.1).

• It is a SyntaxError if a VariableDeclaration occurs within strict code and its Identifier is eval or arguments (13.2.2).

• Strict mode code may not include a WithStatement. The occurrence of a WithStatement in such a context is an SyntaxError (13.10).

• It is a SyntaxError if a TryStatement with a Catch occurs within strict code and the Identifier of the Catch production is eval or arguments (13.14)

• It is a SyntaxError if the identifier eval or arguments appears within the FormalParameters of a strict mode FunctionDeclaration or FunctionExpression (14.1)

• A strict mode function may not have two or more formal parameters that have the same name. An attempt to create such a function using a FunctionDeclaration, FunctionExpression, or Function constructor is a SyntaxError (14.1, 19.2.1).

• An implementation may not extend, beyond that defined in this specification, the meanings within strict mode functions of properties named caller or arguments of function instances. ECMAScript code may not create or modify properties with these names on function objects that correspond to strict mode functions (9.1.16.3, 9.1.16.4, 9.2.5).

• It is a SyntaxError to use within strict mode code the identifiers eval or arguments as the Identifier of a FunctionDeclaration or FunctionExpression or as a formal parameter name (14.1). Attempting to dynamically define such a strict mode function using the Function constructor (19.2.1) will throw a SyntaxError exception.
Annex D
(informative)
Corrections and Clarifications with Possible Compatibility Impact

In Edition 6

15.9.1.14: Previous editions permitted the TimeClip abstract operation to return either +0 or −0 as the representation of a 0 time value. The 6th Edition specifies that +0 always returned. This means that for the 6th Edition the time value of a Date object is never observably −0 and methods that return time values never return −0.

15.9.1.15: If a time zone offset is not present, the local time zone is used. Edition 5.1 incorrectly stated that a missing time zone should be interpreted as "z".

15.9.5.2: Previous editions did not specify the value returned by Date.prototype.toString when this time value is NaN. The 6th Edition specifies the result to be the String value is "Invalid Date"

In Edition 5.1

Clause references in this list refer to the clause number using in Edition 5.1.

7.8.4: CV definitions added for DoubleStringCharacter :: LineContinuation and SingleStringCharacter :: LineContinuation.

10.2.1.1.3: The argument S is not ignored. It controls whether an exception is thrown when attempting to set an immutable binding.

10.2.1.2.2: In algorithm step 5, true is passed as the last argument to [[DefineOwnProperty]].

10.5: Former algorithm step 5.e is now 5.f and a new step 5.e was added to restore compatibility with 3rd Edition when redefining global functions.

11.5.3: In the final bullet item, use of IEEE 754 round-to-nearest mode is specified.

12.6.3: Missing ToBoolean restored in step 3.a.ii of both algorithms.

12.6.4: Additional final sentences in each of the last two paragraphs clarify certain property enumeration requirements.

12.7, 12.8, 12.9: BNF modified to clarify that a continue or break statement without an Identifier or a return statement without an Expression may have a LineTerminator before the semi-colon.

12.14: Step 3 of algorithm 1 and step 2.a of algorithm 3 are corrected such that the value field of B is passed as a parameter rather than B itself.

15.1.2.2: In step 2 of algorithm, clarify that S may be the empty string.

15.1.2.3: In step 2 of algorithm clarify that trimmedString may be the empty string.

15.1.3: Added notes clarifying that ECMAScript’s URI syntax is based upon RFC 2396 and not the newer RFC 3986. In the algorithm for Decode, a step was removed that immediately preceded the current step 4.d.vii.10.a because it tested for a condition that cannot occur.

15.2.3.7: Corrected use of variable P in steps 5 and 6 of algorithm.
15.2.4.2: Edition 5 handling of `undefined` and `null` as this value caused existing code to fail. Specification modified to maintain compatibility with such code. New steps 1 and 2 added to the algorithm.

15.3.3.3: Steps 5 and 7 of Edition 5 algorithm have been deleted because they imposed requirements upon the `argArray` argument that are inconsistent with other uses of generic array-like objects.

15.4.3.12: In step 9.a, incorrect reference to `relativeStart` was replaced with a reference to `actualStart`.

15.4.3.15: Clarified that the default value for `fromIndex` is the length minus 1 of the array.

15.4.3.18: In step 10 (corresponding to step 8 in 5.1) of the algorithm, `undefined` is now the specified return value.

15.4.3.22: In step 11.d.iii (corresponding to 9.c.ii in 5.1) the first argument to the `[[Call]]` internal method has been changed to `undefined` for consistency with the definition of `Array.prototype.reduce`.

15.4.5.1: In Algorithm steps 3.i.i and 3.i.iii the variable name was inverted resulting in an incorrectly inverted test.

15.5.4.9: Normative requirement concerning canonically equivalent strings deleted from paragraph following algorithm because it is listed as a recommendation in NOTE 2.

15.5.4.14: In `split` algorithm step 11.a and 13.a, the positional order of the arguments to `SplitMatch` was corrected to match the actual parameter signature of `SplitMatch`. In step 13.a.iii.7.d, `lengthA` replaces `A.length`.

15.5.5.2: In first paragraph, removed the implication that the individual character property access had “array index” semantics. Modified algorithm steps 3 and 5 such that they do not enforce “array index” requirement.

15.9.1.15: Specified legal value ranges for fields that lacked them. Eliminated “time-only” formats. Specified default values for all optional fields.

15.10.2.2: The step numbers of the algorithm for the internal closure produced by step 2 were incorrectly numbered in a manner that implied that they were steps of the outer algorithm.

15.10.2.6: In the abstract operation `IsWordChar` the first character in the list in step 3 is “a” rather than “A”.

15.10.2.8: In the algorithm for the closure returned by the abstract operation `CharacterSetMatcher`, the variable defined by step 3 and passed as an argument in step 4 was renamed to `ch` in order to avoid a name conflict with a formal parameter of the closure.

15.10.6.2: Step 9.e was deleted because it performed an extra increment of `i`.

15.11.1.1: Removed requirement that the `message` own property is set to the empty String when the `message` argument is `undefined`.

15.11.1.2: Removed requirement that the `message` own property is set to the empty String when the `message` argument is `undefined`.

15.11.4.4: Steps 6-10 modified/added to correctly deal with missing or empty `message` property value.

15.11.1.2: Removed requirement that the `message` own property is set to the empty String when the `message` argument is `undefined`.

15.12.3: In step 10.b.iii of the `JA` abstract operation, the last element of the concatenation is “]”.

B.2.1: Added to NOTE that the encoding is based upon RFC 1738 rather than the newer RFC 3986.

Annex C: An item was added corresponding to 7.6.12 regarding `FutureReservedWords` in strict mode.
In Edition 5

Clause references in this list refer to the clause number using in Edition 5.1.

Throughout: In the Edition 3 specification the meaning of phrases such as "as if by the expression new Array()" are subject to misinterpretation. In the Edition 5 specification text for all internal references and invocations of standard built-in objects and methods has been clarified by making it explicit that the intent is that the actual built-in object is to be used rather than the current dynamically resolved value of the correspondingly identifier binding.

11.8.1: ECMAScript generally uses a left to right evaluation order, however the Edition 3 specification language for the > and <= operators resulted in a partial right to left order. The specification has been corrected for these operators such that it now specifies a full left to right evaluation order. However, this change of order is potentially observable if side-effects occur during the evaluation process.

11.1.4: Edition 5 clarifies the fact that a trailing comma at the end of an ArrayInitialiser does not add to the length of the array. This is not a semantic change from Edition 3 but some implementations may have previously misinterpreted this.

11.2.3: Edition 5 reverses the order of steps 2 and 3 of the algorithm. The original order as specified in Editions 1 through 3 was incorrectly specified such that side-effects of evaluating Arguments could affect the result of evaluating MemberExpression.

12.4: In Edition 3, an object is created, as if by new Object() to serve as the scope for resolving the name of the exception parameter passed to a catch clause of a try statement. If the actual exception object is a function and it is called from within the catch clause, the scope object will be passed as the this value of the call. The body of the function can then define new properties on its this value and those property names become visible identifiers bindings within the scope of the catch clause after the function returns. In Edition 5, when an exception parameter is called as a function, undefined is passed as the this value.

13: In Edition 3, the algorithm for the production FunctionExpression with an Identifier adds an object created as if by new Object() to the scope chain to serve as a scope for looking up the name of the function. The identifier resolution rules (10.1.4 in Edition 3) when applied to such an object will, if necessary, follow the object's prototype chain when attempting to resolve an identifier. This means all the properties of Object.prototype are visible as identifiers within that scope. In practice most implementations of Edition 3 have not implemented this semantics. Edition 5 changes the specified semantics by using a Declarative Environment Record to bind the name of the function.

14: In Edition 3, the algorithm for the production SourceElements: SourceElements SourceElement did not correctly propagate statement result values in the same manner as Block. This could result in the eval function producing an incorrect result when evaluating a Program text. In practice most implementations of Edition 3 have implemented the correct propagation rather than what was specified in Edition 5.

15.10.6: RegExp.prototype is now a RegExp object rather than an instance of Object. The value of its [[Class]] internal data property which is observable using Object.prototype.toString is now "RegExp" rather than "Object".

Annex E
(informative)

Additions and Changes that Introduce Incompatibilities with Prior Editions

E.1 In the 6th Edition

12.2.3: In Edition 6, Function calls are not allowed to return a Reference value.

13.6: In Edition 6, a terminating semi-colon is no longer required at the end of a do-while statement.

13.6: Prior to Edition 6, an initialisation expression could appear as part of the VariableDeclaration that precedes the in keyword. The value of that expression was always discarded. In Edition 6, the ForIn in that same position does not allow the occurrence of such an initialiser.

13.14: In Edition 6, it is an early error for a Catch clause to contain a var declaration for the same Identifier that appears as the Catch clause parameter. In previous editions, such a variable declaration would be instantiated in the enclosing variable environment but the declaration's Initialiser value would be assigned to the Catch parameter.

14.3: In Edition 6, the function objects that are created as the values of the [[Get]] or [[Set]] attribute of accessor properties in an ObjectLiteral are not constructor functions. In Edition 5, they were constructors.

19.1.3.2 and 19.1.3.3: In Edition 6, all property additions and changes are processed, even if one of them throws an exception. If an exception occurs during such processing, the first such exception is thrown after all properties are processed. In Edition 5, processing of property additions and changes immediately terminated when the first exception occurred.

19.1.3.5: In Edition 6, if the argument to Object.freeze is not an object it is treated as if it was a non-extensible ordinary object with no own properties. In Edition 5, a non-object argument always causes a TypeError to be thrown.

19.1.3.6: In Edition 6, if the argument to Object.getOwnPropertyDescriptor is not an object an attempt is make to coerce the argument using ToObject. If the coercion is successful the result is used in place of the original argument value. In Edition 5, a non-object argument always causes a TypeError to be thrown.

19.1.3.8: In Edition 6, if the argument to Object.getOwnPropertyNames is not an object an attempt is make to coerce the argument using ToObject. If the coercion is successful the result is used in place of the original argument value. In Edition 5, a non-object argument always causes a TypeError to be thrown.

19.1.3.9: In Edition 6, if the argument to Object.getPrototypeOf is not an object an attempt is make to coerce the argument using ToObject. If the coercion is successful the result is used in place of the original argument value. In Edition 5, a non-object argument always causes a TypeError to be thrown.

19.1.3.11: In Edition 6, if the argument to Object.isExtensible is not an object it is treated as if it was a non-extensible ordinary object with no own properties. In Edition 5, a non-object argument always causes a TypeError to be thrown.

19.1.3.12: In Edition 6, if the argument to Object.isFrozen is not an object it is treated as if it was a non-extensible ordinary object with no own properties. In Edition 5, a non-object argument always causes a TypeError to be thrown.
19.1.3.13: In Edition 6, if the argument to `Object.isSealed` is not an object it is treated as if it was a non-extensible ordinary object with no own properties. In Edition 5, a non-object argument always causes a `TypeError` to be thrown.

19.1.3.14: In Edition 6, if the argument to `Object.keys` is not an object an attempt is made to coerce the argument using `ToObject`. If the coercion is successful the result is used in place of the original argument value. In Edition 5, a non-object argument always causes a `TypeError` to be thrown.

19.1.3.16: In Edition 6, if the argument to `Object.preventExtensions` is not an object it is treated as if it was a non-extensible ordinary object with no own properties. In Edition 5, a non-object argument always causes a `TypeError` to be thrown.

19.1.3.18: In Edition 6, if the argument to `Object.seal` is not an object it is treated as if it was a non-extensible ordinary object with no own properties. In Edition 5, a non-object argument always causes a `TypeError` to be thrown.

19.2.4.1: In Edition 6, the `length` property of function instances is configurable. In previous editions it was non-configurable.

19.3.3: In Edition 6, the Boolean prototype object is not a Boolean instance. In previous editions it was a Boolean instance whose Boolean value was `false`.

20.1.3: In Edition 6, the Number prototype object is not a Number instance. In previous editions it was a Number instance whose number value was `+0`.

20.3.4: In Edition 6, the Date prototype object is not a Date instance. In previous editions it was a Date instance whose `TimeValue` was `NaN`.

22.1.3: In Edition 6, the Array prototype object is not a Array instance. In previous editions it was an Array instance with a length property whose value was `+0`.

21.1.3: In Edition 6, the String prototype object is not a String instance. In previous editions it was a String instance whose String value was the empty string.

21.2.5: In Edition 6, the RegExp prototype object is not a RegExp instance. In previous editions it was a RegExp instance whose pattern is the empty string.

22.1.3: In Edition 6, the Array prototype object is not a Array instance. In previous editions it was an Array instance with a length property whose value was `+0`.

E.2 In the 5th Edition

Clause references in this list refer to the clause number using in Edition 5.1.

7.1: Unicode format control characters are no longer stripped from ECMAScript source text before processing. In Edition 5, if such a character appears in a `StringLiteral` or `RegularExpressionLiteral` the character will be incorporated into the literal where in Edition 3 the character would not be incorporated into the literal.

7.2: Unicode character `<BOM>` is now treated as whitespace and its presence in the middle of what appears to be an identifier could result in a syntax error which would not have occurred in Edition 3.

7.3: Line terminator characters that are preceded by an escape sequence are now allowed within a string literal token. In Edition 3 a syntax error would have been produced.
7.8.5: Regular expression literals now return a unique object each time the literal is evaluated. This change is detectable by any programs that test the object identity of such literal values or that are sensitive to the shared side effects.

7.8.5: Edition 5 requires early reporting of any possible RegExp constructor errors that would be produced when converting a `RegularExpressionLiteral` to a RegExp object. Prior to Edition 5 implementations were permitted to defer the reporting of such errors until the actual execution time creation of the object.

7.8.5: In Edition 5 unescaped "\" characters may appear as a `CharacterClass` in a regular expression literal. In Edition 3 such a character would have been interpreted as the final character of the literal.

10.4.2: In Edition 5, indirect calls to the `eval` function use the global environment as both the variable environment and lexical environment for the eval code. In Edition 3, the variable and lexical environments of the caller of an indirect `eval` was used as the environments for the eval code.

15.4.3: In Edition 5 all methods of `Array.prototype` are intentionally generic. In Edition 3 `toString` and `toLocaleString` were not generic and would throw a `TypeError` exception if applied to objects that were not instances of `Array`.

10.6: In Edition 5 the array indexed properties of argument objects that correspond to actual formal parameters are enumerable. In Edition 3, such properties were not enumerable.

15: Implementations are now required to ignore extra arguments to standard built-in methods unless otherwise explicitly specified. In Edition 3 the handling of extra arguments was unspecified and implementations were explicitly allowed to throw a `TypeError` exception.

15.1.1: The value properties `NaN`, `Infinity`, and `undefined` of the Global Object have been changed to be read-only properties.

15.1.2.1. Implementations are no longer permitted to restrict the use of `eval` in ways that are not a direct call. In addition, any invocation of `eval` that is not a direct call uses the global environment as its variable environment rather than the caller's variable environment.

15.1.2.2: The specification of the function `parseInt` no longer allows implementations to treat Strings beginning with a \ character as octal values.

15.3.3.3: In Edition 3, a `TypeError` is thrown if the second argument passed to `Function.prototype.apply` is neither an array object nor an arguments object. In Edition 5, the second argument may be any kind of generic array-like object that has a valid `length` property.

15.3.3.4: In Edition 3 passing `undefined` or `null` as the first argument to either `Function.prototype.apply` or `Function.prototype.call` causes the global object to be passed to
the indirectly invoked target function as the this value. If the first argument is a primitive value the result of calling ToObject on the primitive value is passed as the this value. In Edition 5, these transformations are not performed and the actual first argument value is passed as the this value. This difference will normally be unobservable to existing ECMAScript Edition 3 code because a corresponding transformation takes place upon activation of the target function. However, depending upon the implementation, this difference may be observable by host object functions called using apply or call. In addition, invoking a standard built-in function in this manner with null or undefined passed as the this value will in many cases cause behaviour in Edition 5 implementations that differ from Edition 3 behaviour. In particular, in Edition 5 built-in functions that are specified to actually use the passed this value as an object typically throw a TypeError exception if passed null or undefined as the this value.

15.3.4.2: In Edition 5, the prototype property of Function instances is not enumerable. In Edition 3, this property was enumerable.

15.5.5.2: In Edition 5, the individual characters of a String object’s [[StringData]] may be accessed as array indexed properties of the String object. These properties are non-writable and non-configurable and shadow any inherited properties with the same names. In Edition 3, these properties did not exist and ECMAScript code could dynamically add and remove writable properties with such names and could access inherited properties with such names.

15.9.4.2: Date.parse is now required to first attempt to parse its argument as an ISO format string. Programs that use this format but depended upon implementation specific behaviour (including failure) may behave differently.

15.10.2.12: In Edition 5, \s now additionally matches <BOM>.

15.10.4.1: In Edition 3, the exact form of the String value of the source property of an object created by the RegExp constructor is implementation defined. In Edition 5, the String must conform to certain specified requirements and hence may be different from that produced by an Edition 3 implementation.

15.10.6.4: In Edition 3, the result of RegExp.prototype.toString need not be derived from the value of the RegExp object’s source property. In Edition 5 the result must be derived from the source property in a specified manner and hence may be different from the result produced by an Edition 3 implementation.

15.11.4.3: In Edition 5, if an initial value for the message property of an Error object is not specified via the Error constructor the initial value of the property is the empty String. In Edition 3, such an initial value is implementation defined.

15.11.4.4: In Edition 3, the result of Error.prototype.toString is implementation defined. In Edition 5, the result is fully specified and hence may differ from some Edition 3 implementations.

15.12: In Edition 5, the name JSON is defined in the global environment. In Edition 3, testing for the presence of that name will show it to be undefined unless it is defined by the program or implementation.
### Static Semantic Rule Cross Reference

**TODO:** This Table is out of date and incomplete.

  SealedObjectLiteral
  FunctionExpression
  ArrowFunction
  ValueLiteral

CallExpression :
  CallExpression <| TriangleLiteral

26.2.1.1 15.2.3.15 Object.isObject ( O )

When the isObject function is called with argument O, the following steps are taken:

1. If Type(O) is Object return true.
2. Return false.

15.5.4.25 String.prototype.toArray()

The following steps are taken:

1. Let O be CheckObjectCoercible(this value).
2. Let S be ToString(O).
3. ReturnIfAbrupt(S).
4. Let len be the number of characters in S.
5. Let array be the result of the abstract operation ArrayCreate with argument len.
6. Let n be 0
7. Repeat, while n < len:
   a. Let c be the character at position n in S.
   b. Call the [[DefineOwnProperty]] internal method of array with arguments ToString(n), the PropertyDescriptor { [[Value]]: c, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true}, and false.
   c. Increment n by 1.
8. Return array.

The length property of the toArray method is 0.

NOTE 1 Returns an Array object with elements corresponding to the characters of this object (converted to a String).

NOTE 2 The toArray function is intentionally generic; it does not require that its this value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.
**Static Semantics: TopLevelLexicallyDeclaredNames**

OuterStatementList : OuterStatementList OuterItem

1. Let names be TopLevelLexicallyDeclaredNames of OuterStatementList.
2. Append to names the elements of the TopLevelLexicallyDeclaredNames of OuterItem.
3. Return names.

OuterItem : StatementListItem

1. Return a new empty List.

StatementListItem : Declaration

1. If Declaration is Declaration ; FunctionDeclaration, then return a new empty List.
2. Return the BoundNames of Declaration.

26.2.2.1 Static Semantics

Static Semantics: Early Errors

BindingPattern : Irrefutableopt ObjectBindingPattern

- It is a Syntax Error if the BoundNames of ObjectBindingPattern contains the string "eval" or the string "arguments".

BindingPattern : Irrefutableopt ArrayBindingPattern

- It is a Syntax Error if the BoundNames of ArrayBindingPattern contains the string "eval" or the string "arguments".

Static Semantics: BoundNames

BindingPattern : Irrefutableopt ObjectBindingPattern
1. Return the BoundNames of ObjectBindingPattern.

BindingPattern : Irrefutableopt ArrayBindingPattern
1. Return the BoundNames of ArrayBindingPattern.

ObjectBindingPattern : { }
1. Return an empty List.

ArrayBindingPattern : [ Elisionopt ]
1. Return an empty List.

ArrayBindingPattern : [ Elisionopt BindingRestElement ]
1. Return the BoundNames of BindingRestElement.

ArrayBindingPattern : [ BindingElementList , Elisionopt ]
1. Return the BoundNames of BindingElementList.

ArrayBindingPattern : [ BindingElementList , Elisionopt BindingRestElement ]
1. Let names be BoundNames of BindingElementList.
2. Append to names the elements of BoundNames of BindingRestElement.
3. Return names.

BindingPropertyList : Irrefutableopt BindingProperty
1. Return the BoundNames of BindingProperty.

BindingPropertyList : BindingPropertyList , Irrefutableopt BindingProperty
1. Let names be BoundNames of BindingPropertyList.
2. Append to names the elements of BoundNames of BindingProperty.
3. Return names.

BindingElementList : Elisionopt BindingElement
1. Return BoundNames of BindingElement.
BindingElementList : BindingElementList , Elision* BindingElement

1. Let names be BoundNames of BindingElementList.
2. Append to names the elements of BoundNames of BindingElement.
3. Return names.

BindingProperty : PropertyName : BindingElement
1. Return the BoundNames of BindingElement.

SingletonBinding : BindingIdentifier Initialiser
1. Return the BoundNames of BindingIdentifier.

BindingElement : BindingPattern Initialiser
1. Return the BoundNames of BindingPattern.

26.2.3 8.3.10  ([Enumerate]) (includePrototype, onlyEnumerable)

When the [[Enumerate]] internal method of O is called with Boolean arguments includePrototype and onlyEnumerable, the following steps are taken:

1. Return an Iterator object (reference xxxx) whose next method iterates over all the keys of enumerable property keys of O. If includePrototype is false, then only own properties of O are included. If onlyEnumerable is false, then all properties that do not have private name keys are included. The mechanics and order of enumerating the properties is not specified but must conform to the rules specified below.

Enumerated properties do not include properties whose property key is a private name. Properties of the object being enumerated may be deleted during enumeration. If a property that has not yet been visited during enumeration is deleted, then it will not be visited. If new properties are added to the object being enumerated during enumeration, the newly added properties are not guaranteed to be visited in the active enumeration. A property name must not be visited more than once in any enumeration.

Enumerating the properties of an object includes enumerating properties of its prototype, and the prototype of the prototype, and so on, recursively, but a property of a prototype is not enumerated if it is “shadowed” because some previous object in the prototype chain has a property with the same name. The values of [[Enumerable]] attributes are not considered when determining if a property of a prototype object is shadowed by a previous object on the prototype chain.

The following is an informative algorithm that conforms to these rules:

1. Let only be O.
2. Let proto be the value of the [[Prototype]] internal data property of O.
3. If includePrototype is false or proto is the value null, then
   a. Let propList be a new empty List.
4. Else
   a. Let propList be the result of calling the [[Enumerate]] internal method of proto with arguments true and onlyEnumerable.
5. For each string name that is the property key of an own property of O
   a. Let desc be the result of calling the [[GetOwnProperty]] internal method of O with argument name.
   b. If name is an element of propList, then remove name as an element of propList.
   c. If onlyEnumerable is false or desc.[[Enumerable]] is true, then add name as an element of propList.
6. Order the elements of propList in an implementation defined order.
7. Return propList.
This follow version places function body declarations in scope of parameter initialisers.

26.2.4.9.1.11 ToPositiveInteger

The abstract operation ToInteger converts its argument to an integral numeric value. This abstract operation functions as follows:

1. Let number be the result of calling ToNumber on the input argument.
2. Return.IfAbrupt(number).
3. If number is NaN, return +0.
4. If number is +∞, or −∞, return number.
5. If number ≤ 0, return +0.
6. Return the result of computing floor(number).

26.2.5 Function Declaration Instantiation

NOTE When an execution context is established for evaluating function code a new Declarative Environment Record is created and bindings for each formal parameter, and each function level variable, constant, or function declared in the function are instantiated in the environment record. Formal parameters and functions are initialised as part of this process. All other bindings are initialised during execution of the function code.

Function Declaration Instantiation is performed as follows using arguments `func`, `argumentsList`, and `env`, `func` is the function object that for which the execution context is being established. `env` is the declarative environment record in which bindings are to be created.

1. Let code be the value of the `[[Code]]` internal property of `func`.
2. Let strict be the value of the `[[Strict]]` internal property of `func`.
3. Let formals be the value of the `[[FormalParameterList]]` internal property of `func`.
4. Let parameterNames be the `BoundNames` of `formals`.
5. Let varDeclarations be the `VarScopedDeclarations` of `code`.
6. Let functionsToInitialise be an empty List.
7. Let argumentsObjectNotNeeded be false.
8. For each `d` in `varDeclarations`, in reverse list order do
   a. If `d` is a `FunctionDeclaration` then
      i. NOTE If there are multiple `FunctionDeclarations` for the same name, the last declaration is used.
      ii. Let `fn` be the sole element of the `BoundNames` of `d`.
      iii. If `fn` is `arguments`, then let `argumentsObjectNotNeeded` be true.
      iv. Let `alreadyDeclared` be the result of calling `env`'s `HasBinding` concrete method passing `fn` as the argument.
      v. If `alreadyDeclared` is false, then
         1. Let `status` be the result of calling `env`'s `CreateMutableBinding` concrete method passing `fn` as the argument.
         2. Assert: `status` is never an abrupt completion.
         3. Append `d` to `functionsToInitialise`.
   b. For each String `paramName` in `parameterNames`, do
      a. Let `alreadyDeclared` be the result of calling `env`'s `HasBinding` concrete method passing `paramName` as the argument.
      b. If `alreadyDeclared` is false, then
         i. Let `paramName` be `arguments`, then let `argumentsObjectNotNeeded` be true.
         ii. Let `status` be the result of calling `env`'s `CreateMutableBinding` concrete method passing `paramName` as the argument.
         iii. Assert: `status` is never an abrupt completion.
         iv. Call `env`'s `InitialiseBinding` concrete method passing `paramName`, and `undefined` as the arguments.
10. NOTE If there is a function declaration or formal parameter with the name "arguments" then an argument object is not created.
11. If `argumentsObjectNotNeeded` is false, then
a. If strict is true, then
   i. Call env's CreateImmutableBinding concrete method passing the String "arguments" as the argument.
   b. Else,
      i. Call env's CreateMutableBinding concrete method passing the String "arguments" as the argument.

12. Let varNames be the VarDeclaredNames of code.
13. For each String varName in varNames, in list order do
   a. Let alreadyDeclared be the result of calling env's HasBinding concrete method passing varName as the argument.
   b. NOTE A VarDeclaredNames is only instantiated and initialised here if it is not also the name of a formal parameter or a FunctionDeclarations.
   c. If alreadyDeclared is false, then
      i. Call env's CreateMutableBinding concrete method passing varName as the argument.

14. Let lexDeclarations be the LexicalDeclarations of code.
15. For each element d in lexDeclarations do
   a. NOTE A lexically declared name cannot be the same as a function declaration, formal parameter, or a var name. Lexically declared names are only instantiated here but not initialised.
   b. For each element dn of the BoundNames of d do
      i. If IsConstantDeclaration of d is true, then
         1. Call env's CreateImmutableBinding concrete method passing dn as the argument.
      ii. Else,
         1. Call env's CreateMutableBinding concrete method passing dn and false as the arguments.
   16. For each FunctionDeclaration f in functionsToInitialise, do
      a. Let fn be the sole element of the BoundNames of f.
      b. Let fo be the result of performing InstantiateFunctionObject for f with argument env.
      c. Call env's SetMutableMinding concrete method passing fn, fo, and false as the arguments.
   17. NOTE Function declaration are initialised prior to parameter initialisation so that default value expressions may reference them. It is not extended code. "arguments" is not initialised until after parameter initialization.
   18. Let ao be the result of InstantiateArgumentsObject with argument argumentsList.
   19. NOTE If argumentsObjectNotNeeded is true then the value of ao is not directly observable to ECMAScript code and need not actually exist. In this case, its use in the above steps is strictly as a device for specifying formal parameter initialisation semantics.
   20. If argumentsObjectNotNeeded is false, then
      a. If strict is true, then
         i. Perform the abstract operation CompleteStrictArgumentsObject with argument ao.
      b. Else,
         i. Perform the abstract operation CompleteMappedArgumentsObject with arguments ao, func, formalStatus, and env.
      c. Call env's InitialiseBinding concrete method passing 'arguments' and ao as arguments.
   21. Let formalStatus be the result of performing Binding Initialisation for formals with ao and undefined as arguments.
   22. ReturnIfAbrupt(formalStatus).
   23. Return NormalCompletion(empty).

F.1.1 The __proto__ pseudo property

F.1.1.1 Object.prototype.__proto_

The initial value of the __proto__ property of the Object prototype object is a data property whose initial value is null. This property initially has the attributes { [[Writable]]: true, [[Enumerable]]: false, [[Configurable]]: true }. Manipulations of this property as tracked by the Boolean valued primordial internal variable UnderscoreProtoEnabled. The default initial value of UnderscoreProtoEnabled is true only if this property is initially present on the primordial Object prototype object.

NOTE Any modification of this property or its attributes causes UnderscoreProtoEnabled to be set to false.

Commented [AWB206]: TODO: don't create an arguments binding for arrow functions (and perhaps for concise methods)

Commented [AWB207]: The section and algorithm reference in this draft are based upon the ES5.1 spec. When the corresponding sections of this document are stable, this section will need to be updated.

Commented [AWB208]: This material is going to be made mandatory and integrated into the main body of the spec.

Commented [AWB209]: This is anticipating new specification material related to Module loaders and establishing a primordial environment. The basic assumption is that a module loader must be able to disable this feature. This seems to suggest that the ability to do so must exist in the module loader APIs even if this feature is not present in an implementation.
F.1.1.2 Changes To Internal Methods

The definition of the [[Get]] internal method given in 8.12.3 is replaced with the following:

1. If \( P \) is the string value "\_\_proto\_" and UnderscoreProtoEnabled is \text{true}, then
   a. Let desc be the result of calling the [[GetProperty]] internal method of \( O \) with property name \( P \).
   b. If desc is not \text{undefined} and was created by step 1.a to describe the property defined in B.3.1.1 then,
      i. Return the value of the [[Prototype]] internal data property of \( O \).
2. Continue by executing the steps of 8.12.3 starting with step 1.

The definition of the [[Put]] internal method given in 8.12.5 is replaced with the following:

1. If \( P \) is the string value "\_\_proto\_" and UnderscoreProtoEnabled is \text{true} and \( O \) is not the standard built-in Object prototype object, then
   a. Let desc be the result of calling the [[GetProperty]] internal method of \( O \) with property name \( P \).
   b. If desc is not \text{undefined} and was created by step 1.a to describe the property defined in B.3.1.1 then,
      i. If the type of \( V \) is neither Object or Null, return.
      ii. Set the value of the [[Prototype]] internal data property of \( O \) to \( V \).
      iii. Return.
2. Continue by executing the steps of 8.12.5 starting with step 1.

The definition of the [[Delete]] internal method given in 8.12.7 is replaced with the following:

1. If UnderscoreProtoEnabled is \text{true} and \( P \) is the string value "\_\_proto\_" and \( O \) is the standard built-in Object prototype object, then
   a. Set UnderscoreProtoEnabled to \text{false}.
2. Continue by executing the steps of 8.12.7 starting with step 1.

The definition of the [[DefineOwnProperty]] internal method given in 8.12.9 is replaced with the following:

1. If UnderscoreProtoEnabled is \text{true} and \( P \) is the string value "\_\_proto\_" and \( O \) is the standard built-in Object prototype object, then
   a. If any attribute contained in Desc is not present or has a different value from the corresponding attribute in \( \{\text{Writable}:\text{true}, \text{Enumerable}:\text{true}, \text{Configurable}:\text{true}\} \) then,
      i. Set UnderscoreProtoEnabled to \text{false}.
2. Continue by executing the steps of 8.12.9 starting with step 1.

26.2.5.1 \_\_15.18.1.14 Reflect.freeze (target)

When the \text{freeze} function is called with argument \text{target} the following steps are taken:

1. Let \( \text{obj} \) be ToObject(\text{target}).
2. Return(Absent(\text{obj})).
3. Return the result of calling the [[Freeze]] internal method of \( \text{obj} \).

26.2.5.2 \_\_15.18.1.15 Reflect.seal (target)

When the \text{seal} function is called with argument \text{target} the following steps are taken:

1. Let \( \text{obj} \) be ToObject(\text{target}).
2. Return(Absent(\text{obj})).
3. Return the result of calling the [[Seal]] internal method of \( \text{obj} \).
26.2.5.3 15.18.1.16 Reflect.isFrozen (target)

When the `isFrozen` function is called with argument `target` the following steps are taken:

1. Let `obj` be `ToObject(target)`.  
2. ReturnIfAbrupt(`obj`).  
3. Return the result of calling the `[[IsFrozen]]` internal method of `obj`.

26.2.5.4 15.18.1.17 Reflect.isSealed (target)

When the `isSealed` function is called with argument `target` the following steps are taken:

1. Let `obj` be `ToObject(target)`.  
2. ReturnIfAbrupt(`obj`).  
3. Return the result of calling the `[[IsSealed]]` internal method of `obj`.

F.1.1.3 __proto__ Object Initialisers

Definitions of two algorithms in 11.1.5 are replaced with the following:

The production `PropertyDefinitionList : PropertyDefinition` is evaluated as follows:

1. Let `obj` be the result of the abstract operation `ObjectCreate` with the intrinsic object `%ObjectPrototype%` as its argument.  
2. Let `propld` be the result of evaluating `PropertyDefinition`.  
3. If `propld.name` is the string value "__proto__" and UnderscoreProtoEnabled is true and `IsDataDescriptor(propld.descriptor)` is true, then
   a. Let `v` be `propld.descriptor.value`.  
   b. If `desc` be `propld.descriptor`  
   c. If the type of `v` is either Object or Null,  
   i. Set the value of the `[[Prototype]]` internal data property of `obj` to `v`.  
   d. Return `obj`.  
4. Call the `[[DefineOwnProperty]]` internal method of `obj` with arguments `propld.name`, `propld.descriptor`, and `false`.  
5. Return `obj`.

The production `PropertyDefinitionList : PropertyDefinitionList, PropertyDefinition` is evaluated as follows:

1. Let `obj` be the result of evaluating `PropertyDefinitionList`.  
2. Let `propld` be the result of evaluating `PropertyDefinition`.  
3. Let `previous` be the result of calling the `[[GetOwnProperty]]` internal method of `obj` with argument `propld.name`.  
4. If `previous` is not `undefined` then throw a SyntaxError exception if any of the following conditions are true
   a. This production is contained in strict code and `IsDataDescriptor(previous)` is true and `IsDataDescriptor(propld.descriptor)` is true.  
   b. `IsDataDescriptor(previous)` is true and `IsAccessorDescriptor(propld.descriptor)` is true.  
   c. `IsAccessorDescriptor(previous)` is true and `IsDataDescriptor(propld.descriptor)` is true.  
   d. `IsAccessorDescriptor(previous)` is true and `IsAccessorDescriptor(propld.descriptor)` is true and either both `previous` and `propld.descriptor` have `[[Get]]` fields or both `previous` and `propld.descriptor` have `[[Set]]` fields  
5. If `propld.name` is the string value "__proto__" and UnderscoreProtoEnabled is true and `IsDataDescriptor(propld.descriptor)` is true, then
   a. Let `v` be `propld.descriptor.value`.  
   b. If `desc` be `propld.descriptor`  
   c. If the type of `v` is either Object or Null,  
   i. Set the value of the `[[Prototype]]` internal data property of `obj` to `v`.  
   d. Return `obj`.  

470 © Ecma International 2013
6. Call the `[[DefineOwnProperty]]` internal method of `obj` with arguments `propId.name`, `propId.descriptor`, and `false`.
7. Return `obj`.
