STANDARD ECMA-101

OPEN DOCUMENT ARCHITECTURE (ODA) AND INTERCHANGE FORMAT

Volume 1
Part 1 – Introduction and General Principles
Part 2 – Document Structures
Part 3 – Document Profile

2nd Edition – December 1988
Brief History

In 1985, ECMA/TC29 published Standard ECMA 101, Office Document Architecture, in order to facilitate the interchange of documents.

In the meantime, work has started in ISO and CCITT, resulting in the preparation of ISO 8613, “Office Document Architecture (ODA) and interchange format”. Experts of TC29 participated to the work, and acted as editors of most of the parts of the ISO and CCITT documents.

This second edition of Standard ECMA–101 has been prepared by ECMA/TC29 to align ECMA–101 with the current ISO/CCITT publications.

Development of this ECMA Standard has been in parallel with:

At present this Standard consists of seven parts:
- Part 1. Introduction and General Principles;
- Part 2. Document Structures;
- Part 4. Document Profile;
- Part 5. Open Document Interchange Format (ODIF);
- Part 6. Character Content Architectures;
- Part 7. Raster Graphics Content Architectures;

At present, there is no part 3.

Further parts may be added to this Standard.

This ECMA Standard is published in two volumes: Volume 1, including parts 1, 2 and 4, and Volume 2 including parts 5, 6, 7 and 8. This is Volume 1.

This second edition of ECMA–101 has been approved by the General Assembly of ECMA of 15 December 1988.

## Part 2

1. **INTRODUCTION**  
   1.1 Scope  
   1.2 Normative References  
   1.3 Definitions, symbols and abbreviations  
      1.3.1 Definitions  
      1.3.2 Conventions

2. **ARCHITECTURAL PRINCIPLES**  
   2.1 Architectural concepts  
   2.2 Structural model of a document  
      2.2.1 Specific structures  
      2.2.2 Content of a document  
      2.2.3 Generic structures  
   2.3 Descriptive representation of a document  
      2.3.1 Constituents of a document  
      2.3.2 Content portion descriptions  
      2.3.3 Object descriptions  
      2.3.4 Object class descriptions  
      2.3.5 Styles  
      2.3.6 Document profile  
      2.3.7 Document class descriptions  
      2.3.8 Generic-documents  
      2.3.9 External-document class description  
      2.3.10 Resource-documents  
      2.3.11 Classes of document architecture  
      2.3.12 Sets of constituents  
   2.4 Document processing model  
      2.4.1 The editing process  
      2.4.2 The layout process  
      2.4.3 The imaging process  
   2.5 Roles of the document architecture constituents in document processing  
      2.5.1 Editing process  
      2.5.2 Layout process  
      2.5.3 Imaging process
3. DOCUMENT STRUCTURES
  3.1 Specific structures
      3.1.1 General principles
      3.1.2 Sequential order
      3.1.3 Content portions
  3.2 Specific logical structures
      3.2.1 Document logical root
      3.2.2 Composite logical objects
      3.2.3 Basic logical objects
  3.3 Specific layout structure
      3.3.1 Objects of the layout structure
      3.3.2 Positioning layout objects
      3.3.3 Naming of edges of frames and blocks
      3.3.4 Measurement
      3.3.5 Borders of frames and blocks
  3.4 Documents containing both specific structures
  3.5 Generic structures
      3.5.1 General principles
      3.5.2 Generator and factor sets of object class descriptions
      3.5.3 Complete generator sets of object class descriptions
      3.5.4 Generation of structures
      3.5.5 Content in generic structures
      3.5.6 Generic logical structure
      3.5.7 Generic layout structure
      3.5.8 Resource-document

4. INTERFACE BETWEEN THE DOCUMENT ARCHITECTURE AND CONTENT
  4.1 General concept
  4.2 Specification of a content architecture
  4.3 Interface information
      4.3.1 Interface between a content architecture and the document profile
      4.3.2 Interface between a content architecture and a basic component description
      4.3.3 Interface between a content architecture and a content portion

5. ATTRIBUTE DEFINITIONS
  5.1 General principles of attributes
      5.1.1 Attribute categorisation
      5.1.2 Attribute values
      5.1.3 Expressions
  5.2 Attribute specification format
  5.3 Shared attributes
      5.3.1 Identification attributes
      5.3.2 Construction attributes
      5.3.3 Relationship attributes
      5.3.4 Content architecture class attributes
      5.3.5 Miscellaneous attributes
  5.4 Layout attributes
      5.4.1 Property attributes
      5.4.2 Formatting attributes
      5.4.3 Imaging attributes
5.4.4 Presentation attributes 114
5.5 Logical attributes 114
  5.5.1 Protection 114
  5.5.2 Layout style 114
5.6 Layout style attributes 115
  5.6.1 Layout style identifier 115
  5.6.2 Attributes which can be specified for layout styles 116
5.7 Layout directives 115
  5.7.1 Block Alignment 115
  5.7.2 Concatenation 116
  5.7.3 Fill order 117
  5.7.4 Indivisibility 117
  5.7.5 Layout category 118
  5.7.6 Layout object class 118
  5.7.7 New layout object 119
  5.7.8 Offset 120
  5.7.9 Same layout object 120
  5.7.10 Separation 121
  5.7.11 Synchronization 122
  5.7.12 Interactions and precedences among the layout directives 122
  5.7.13 Interactions among attributes affecting the layout process 125
5.8 Presentation style attributes 125
  5.8.1 Presentation style identifier 125
  5.8.2 Attributes which can be specified for presentation styles 125
5.9 Content portion attributes 126
  5.9.1 Identification attributes: Content identifier - logical;
      Content identifier - layout 126
  5.9.2 Common coding attributes: Type of coding 127
  5.9.3 Content information attributes 127
  5.9.4 Coding attributes 128

6. REFERENCE MODEL OF THE DOCUMENT LAYOUT PROCESS 128
6.1 Overview 128
6.2 Content and layout structure generation 129
  6.2.1 Laying out content of a document 129
  6.2.2 Specific layout structure generation 131
6.3 Layout references and categories 131
  6.3.1 Layout categories 131
  6.3.2 Layout object class 134
6.4 The effect of some attributes on the document layout process 134
  6.4.1 New layout object 134
  6.4.2 Same layout object 135
  6.4.3 Indivisibility 135
  6.4.4 Synchronisation 136
  6.4.5 Balance 137
6.5 Layout process for frames 137
  6.5.1 Placement of frames with fixed position 137
  6.5.2 Placement of frames with variable position 137
6.6 Allocation of areas for blocks 140
  6.6.1 Determination of the available area 140
6.7 Alternative representation 142
7. REFERENCE MODEL OF THE DOCUMENT IMAGING PROCESS
   7.1 Imaging order
   7.2 Intersection principles
   7.3 General rules for positioning pages on presentation surfaces
      7.3.1 Nominal page and assured reproduction areas
      7.3.2 Positioning of the page
      7.3.3 Definition of assured reproduction area
      7.3.4 Recto/verso pages
      7.3.5 Positioning of pages on soft copy media
8. DOCUMENT ARCHITECTURE LEVELS
   8.1 Definition of document architecture classes
   8.2 The constituents of document architecture classes
   8.3 Minimum attribute sets
      8.3.1 The minimum sets of attributes applicable to logical component descriptions
      8.3.2 The minimum sets of attributes applicable to layout component descriptions
Appendices
   A Notation used to represent document structures
   B Examples of document structures
   C Examples of document architecture levels
   D Examples of particular document features
   E The defaulting mechanism
   F Attribute summary tables

Standard ECMA–101 – Open Document Architecture (ODA) and Interchange Format

Part 1 – Introduction and General Principles

This second edition of Standard ECMA–101 has been prepared by ECMA/TC29 to align ECMA–101 with the current ISO/CCITT publications.

At present this standard consists of seven parts:
- Part 1, Introduction and General Principles;
- Part 2, Document Structures;
- Part 4, Document Profile;
- Part 5, Open Document Interchange Format (ODIF);
- Part 6, Character Content Architectures;
- Part 7, Raster Graphics Content Architectures;
- Part 8, Geometric Graphics Content Architectures.

At present, there is no part 3.

Further parts may be added to this ECMA Standard.

This part 1 contains five Appendices:
- Appendix A: References to other Standards and Registers;
- Appendix B: Relationship with other Standards;
- Appendix C: Correspondence between CCITT Recommendation T.73 (1984) and ECMA–101
- Appendix D: Principles for the assignment of ASN.1 Object Identifier Values
- Appendix E: Use of MHS/MOTIS to interchange Documents.
1. **SCOPE**

The purpose of this standard ECMA–101 is to facilitate the interchange of documents.

In the context of this Standard, documents are considered to be items such as memoranda, letters, invoices, forms and reports, which may include pictures and tabular material. The content elements used within the documents may include graphic characters, geometric graphics elements and raster graphics elements, all potentially within one document.

*NOTE 1–1*

This Standard is designed to allow for extensions, including typographical features, colour, spreadsheets and additional types of content such as sound.

This Standard applies to the interchange of documents by means of data communications or the exchange of storage media.

It provides for the interchange of documents for either or both of the following purposes:
- to allow presentation as intended by the originator;
- to allow processing, such as editing and reformatting.

The composition of a document in interchange can take several forms:
- formatted form, allowing presentation of the document;
- processable form, allowing processing of the document;
- formatted processable form, allowing both presentation and processing.

This Standard also provides for the interchange of ODA information structures used for the processing of interchanged documents.

Furthermore, this Standard allows for the interchange of documents containing one or more different types of content, such as character text, images, graphics and sound.

This part of ECMA–101
- introduces this standard as a whole;
- gives the references necessary for all the parts;
- defines terms used in the context of This Standard;
- presents the concepts of the document architecture;
- gives an overview of all the parts;
- describes the inter-dependencies of the parts;
- gives an overview of all the parts;
- describes the inter-dependencies of the parts;
- defines conformance to this Standard;
- gives rules for defining document application profiles.

2. **REFERENCES**

- Part 2 – Document structures;
- Part 4 – Document profile;
- Part 5 – Open document interchange format (ODIF);
- Part 6 – Character content architectures;
- Part 7 – Raster graphics content architectures;
- Part 8 – Geometric graphics content architectures.

3. DEFINITIONS

For the purposes of this standard, the following definitions apply.

3.1 Active position
The point at which the action specified by the next character is to be effected.

3.2 Aligned around
A tabulation alignment that positions the sequence of character images for a specified character string such that the position point of the character image of the first instance of a specified group of characters within that string is positioned at the tabulation stop.

3.3 Aspect ratio
The ratio of the dimension of a pel array in direction of the pel path to the dimension in the direction of the line progression.

3.4 Assured reproduction area
The rectangular area that remains on the nominal page after deducting an agreed allowance for edge losses.

3.5 Attribute
An element of a constituent of a document that has a name and a value and that expresses a characteristic of this constituent or a relationship with one or more constituents.

3.6 Available area
The area determined by the document layout process into which the content portion is formatted by the content layout process.

3.7 Basic component
A basic logical or layout object, or an object class from which basic logical or layout objects may be derived.

3.8 Basic layout object
An object in the specific layout structure that has no subordinate.

3.9 Basic logical object
An object in the specific logical structure that has no subordinate.

3.10 Basic measurement unit; BMU (abbreviation)
A unit of linear measurement equal to 1/1200 of 25.4 mm.

NOTE 1-2
A locally defined scaling factor may be used to map the document to a particular imaging device.

3.11 Basic value
An attribute value, a control function parameter value or the value of any other capability that is unconditionally allowed in document interchange in the context of a given document application profile.

3.12 Binding
A pair comprising an identifier and a value, where the value may be of any type, may be specified by an expression, and is accessed through use of the binding identifier.

3.13 Block
A basic layout component that corresponds to a rectangular area within a frame or a page.
3.14 **Bottom edge**
The edge of the positioning area of a basic layout object that is in the direction of the line progression.

3.15 **Bottom left corner**
The corner of a layout object that is least progressed in the horizontal direction and most progressed in the vertical direction of this layout object.

3.16 **Bottom right corner**
The corner of a layout object that is most progressed both in the horizontal and vertical directions of this layout object.

3.17 **Centred**
(1) The result of a layout or imaging process that positions the sequence of character images for a line such that the distance from the line home position to the position point of the first character image is approximately equal to the distance from the escapement point of the last character image to the end edge of the positioning area.

(2) A tabulation alignment that positions the sequence of character images for a specified character string such that the distance from the position point of the first character image to the tabulation stop is approximately equal to the distance from the tabulation stop to the escapement point of the last character image.

*NOTE 1–3*
The term “centred” is also used in the parameter “alignment” of the attribute “position” and in the attribute “block alignment”.

3.18 **Character**
A member of a set of elements used for the organization, control and representation of information.

3.19 **Character base line**
A line across a character image, in the horizontal direction when the character image is in its intended viewing orientation.

3.20 **Character image**
The human perceptible rendering of a character on a presentation medium.

3.21 **Character orientation**
The direction of the character baseline relative to the character path.

3.22 **Character path**
The direction of progression of successive character images within a linebox.

3.23 **Character sequence**
A sequence of characters intended to be presented as one or more lines.

3.24 **Character spacing (for constant spacing fonts only)**
The distance between the position points of successive character images when the inter–character space equals zero.

3.25 **Clipped pel array**
The actual pel array to be imaged as determined by taking account of all clipping parameters.

3.26 **Complete generator set**
A constituent of a document consisting of a document root object class description and at least one level of subordinate object class descriptions which are used to control the creation and/or modification of the set of object descriptions representing a corresponding specific structure.
3.27 **Component**  
An object or an object class.

3.28 **Composite component**  
A composite logical or layout object, or an object class from which composite logical or layout objects may be derived.

3.29 **Composite layout object**  
An object in the layout structure that has one or more subordinate objects.

3.30 **Composite logical object**  
An object in the logical structure that has one or more subordinate objects.

3.31 **Constant spacing**  
The characteristic of a font wherein the distance between the position point and the escapement point is the same for all character images.

3.32 **Constituent**  
A set of attributes that is one of the following types: a document profile, an object description, an object class description, a presentation style, a layout style or a content portion description.

3.33 **Content**  
The information conveyed by the document, other than the structural information, and that is intended for human perception.

3.34 **Content architecture**  
Rules for defining the internal structure and representation of the content of basic components in terms of a set of content elements, attributes and control functions, and guidelines for the presentation of the content.

3.35 **Content architecture class**  
The rules for defining the internal structure and representation of the content of basic components in one of a set of forms defined for each type of content element.  
*NOTE* 1–4  
Examples of content architecture classes are formatted form, processable form and formatted processable form in the case of character content elements.

3.36 **Content architecture level**  
An identified subset of the features pertaining to a content architecture class.

3.37 **Content editing process**  
The process that creates new content or modifies previous content.

3.38 **Content element**  
A basic element of the content of a document.

3.39 **Content layout process**  
The process that, interacting with the document layout process, consists of the formatting of content portions into available areas and the determination of the sizes of blocks in accordance with information contained in the presentation styles.

3.40 **Content portion**  
The result of partitioning the content of a document according to its logical and/or layout structure.
3.41 **Content portion description**
A constituent of a document, representing a content portion that consists of content information and attributes to specify the properties of its content information.

3.42 **Content type**
A category of content elements such as graphic characters, raster graphic elements and geometric graphic elements.

3.43 **Control function**
An element of a character set that affects the recording, processing, transmission or interpretation of data, and that has a coded representation consisting of one or more bit combinations.

*NOTE 1–5*
Examples of control functions are Select Graphic Rendition (SGR) in character content architectures and Set Line Type in geometric graphics content architectures.

3.44 **Current layout position**
The identification of a lowest level frame which is maintained during the layout process for each layout stream which occurs.

3.45 **Data structure**
A set of data items and the relationship among them representing the whole or a part of a constituent.

*NOTE 1–6*
The data items constituting a data structure represent attributes of the document, the document profile, the component, the style or the content portion concerned.

3.46 **Description**
A constituent that corresponds to a structural element.

3.47 **Descriptor**
A data structure representing the document profile, an object class description, a layout style, a presentation style or an object description.

3.48 **Document**
A structured amount of information intended for human perception, that can be interchanged as a unit between users and/or systems.

3.49 **Document application profile**
The specification of a combination of features defined in this Standard, intended to form a subset to fulfil the requirements of an application.

3.50 **Document architecture**
(1) Rules for defining the structure of documents, in terms of a set of components and content portions, and the representation of documents in terms of constituents and attributes.
(2) The structural information of a document consisting of the set of one or more of the following structures: specific logical structure, specific layout structure, generic logical structure and/or generic layout structure.

3.51 **Document architecture class**
The rules for defining the structure and representation of documents in formatted form, processable form or formatted processable form.

3.52 **Document architecture level**
An identified subset of the features pertaining to a document architecture class.
3.53 **Document body**
The part of a document that may include a generic logical and layout structure, specific logical and layout structure, layout and presentation styles but excludes the document profile.

3.54 **Document class**
A set of logical object class descriptions, layout object class descriptions, generic content portion descriptions, styles and a document profile, that specifies a set of documents with common characteristics.

3.55 **Document class description**
The specification of a document class.

3.56 **Document layout process**
The process that creates a specific layout structure in accordance with the generic layout structure and information contained in the specific logical structure, the generic logical structure and the layout styles.

3.57 **Document layout root**
The composite object of the specific layout structure at the highest level of the hierarchy.

3.58 **Document logical root**
The composite object of the specific logical structure at the highest level of the hierarchy.

3.59 **Document profile**
A set of attributes which specifies the characteristics of the document as a whole.

3.60 **Document profile level**
An identified subset of the features pertaining to the document profile.

3.61 **Editing process**
The stage of a document processing that consists of the content editing process and the logical structure editing process.

3.62 **End-aligned**
(1) The result of a layout or imaging process that positions the sequence of character images for a line such that the escapement point of the last character image is positioned at the end edge of the positioning area.

(2) A tabulation alignment that positions the sequence of character images for a specified character string such that the escapement point of the last character image is positioned at the tabulation stop.

3.63 **End edge**
The edge of the positioning area of a basic layout object that is in the direction of the character path.

3.64 **Escapement point**
A reference point associated with a character image that is used for positioning of the next character image.

3.65 **External document class**
A document class referred to by the document profile of an interchanged document containing no generic structure.

3.66 **Factor set**
One or more object class descriptions which are used to factorise the attributes of object descriptions representing a specific structure.
3.67 **Filing**
The storage of a document according to some defined method in order to facilitate retrieval of the document.

3.68 **Font**
A set of character images normally with a common design and size.

3.69 **Font size**
The height of the character images in a font.

3.70 **Formatted form**
A form of representation of a document that allows the presentation of the document as intended by the originator and that does not support editing and (re)formatting.

3.71 **Formatted processable form**
A form of representation of the document that allows presentation of the document as intended by the originator and also supports editing and (re)formatting.

3.72 **Formatting**
The carrying out of operations to determine the layout of a document.

3.73 **Frame**
A type of composite layout component that corresponds to a rectangular area within a page or another frame.

3.74 **Generic content portion**
A content portion associated with an object class.

3.75 **Generic content portion description**
A content portion description associated with an object class description.

3.76 **Generic–document**
A structured amount of information intended for the interchange of generic structures, and optionally associated styles and content portions, for use in the processing of interchanged documents.

3.77 **Generic layout structure**
A set of layout object classes and associated generic content portions.

3.78 **Generic logical structure**
A set of logical object classes and associated generic content portions.

3.79 **Geometric graphics element**
A graphic element used to describe an image by geometric graphical means.

*NOTE 1–7*
Geometric graphics elements include those describing primitive geometric shapes such as points, arcs, lines.

3.80 **Graphic character**
A member of a set of graphic symbols used for the representation of information.

*NOTE 1–8*
Graphic characters include simple alphanumeric characters (for example, accented letters) and pictorial characters (for example, mosaics).
3.81 **Graphic element**  
A content element that is capable of having a visual representation.  

*NOTE 1–9  
Three types of graphic elements are distinguished in this standard: graphic characters, geometric graphics elements and raster graphics elements.*

3.82 **Hard line terminator**  
A line terminator that is intended not to be removed in a re-formatting process.

3.83 **Horizontal direction (of a layout object):**  
The direction in a layout object relative to which content architectures may define attributes determined using the horizontal axis of the page.

3.84 **Imaging order**  
The order of precedence of layout objects for imaging in the layout object to which they are immediately subordinate.

3.85 **Imaging process**  
The process of producing a document on a presentation medium in human–perceptible form, making use of the document profile, specific and generic layout structures, presentation styles and content portions.

3.86 **Indentation**  
The result of a layout or imaging process that causes the sequence of character images for a line to begin at a distance from the line home position in the direction of the character path.

3.87 **Initial point**  
(1) The point associated with a basic layout object relative to which all line boxes imaged within that basic layout object are positioned (character content architectures part 6 of this Standard).  
(2) The point associated with a basic layout object relative to which all pels imaged within that basic layout object are positioned (raster graphics content architectures part 7 of this Standard).

3.88 **Interchange**  
The process of transferring a document from an originating system to a receiving system.

3.89 **Interchange data element**  
A data structure representing a constituent of a document.

3.90 **Interchange format**  
The rules for representing a document for the purpose of interchange.

3.91 **Interchange format class**  
A form of interchange format suitable to a specific application.  

*NOTE 1–10  
In this standard, the defined classes differ by the ordering of the interchange data elements or by the coding.*

3.92 **Inter–character space**  
An additional amount of spacing that is included between adjacent character images.

3.93 **Intersection**  
The common area of two or more layout objects that overlap each other partially or fully on the presentation medium.
3.94 Item identifier
A string of characters preceding the first line of characters in a content portion that is used to identify the subsequent text.

3.95 Justified
The result of a layout or imaging process that varies the width of the space character and/or the inter-character space to produce a simultaneously start-aligned and end-aligned presentation of the text.

3.96 Kern
The part of a character which extends beyond its position point or escapement point.

3.97 Layout category
The association of basic logical objects with lowest level frames such that the content of these basic logical objects is placed in the appropriate frames.

3.98 Layout object
An element of the specific layout structure of a document, for example, page, block.

3.99 Layout object class
An element of the generic layout structure from which a set of layout objects with common characteristics may be derived, for example, pages with common headers and footers.

3.100 Layout process
The stage of a document processing that consists of the document layout process and the content layout process.

**NOTE 1–11**
This is also referred to as formatting.

3.101 Layout stream
A set of basic logical objects pertaining to the same layout category.

3.102 Layout structure
(1) The result of dividing and subdividing the content of a document into increasingly smaller parts, on the basis of the presentation, for example, into pages, blocks.
(2) All layout objects and associated content portions forming the layout hierarchy of a document.

3.103 Layout style
A constituent of the document, referred to from a logical component, that guides the creation of a specific layout structure.

3.104 Leading edge
The edge of a frame or block that is orthogonal to the direction of the layout path and that is met first, from the outside of the frame or the block, in the opposite direction of the layout path.

3.105 Left hand edge
The edge of a frame or block that is parallel to the direction of the layout path and that is met first, from the outside of the frame or the block, in the direction at an angle of 270° counterclockwise relative to the direction of the layout path.

3.106 Line box
A rectangular area within which a sequence of character images are positioned.

3.107 Line home position
The point within a line box that is used for positioning that line box.
3.108 **Line progression**

(1) The direction of progression of successive line boxes within a basic layout object (character content architectures part 6 of this Standard).

(2) The direction of progression of successive lines of pels within a basic layout object (raster graphics content architectures part 7 of this Standard).

3.109 **Line spacing**

(1) The distance between two adjacent reference lines within a basic layout object (character content architectures part 6 of this Standard).

(2) The distance between two adjacent lines of pels within a basic layout object (raster graphics content architectures part 7 of this Standard).

3.110 **Line terminator**

A control function or combination of control functions that indicates the end of a line or the end of a character sequence.

3.111 **Logical object**

An element of the specific logical structure of a document which may have a meaning that is significant to the application or user, for example, chapter, section, paragraph.

3.112 **Logical object class**

An element of the generic logical structure from which a set of logical objects with common characteristics may be derived, for example, composite logical objects representing sections with a common internal structure.

3.113 **Logical structure**

(1) The result of dividing and subdividing the content of a document into increasingly smaller parts, on the basis of the human-perceptible meaning of the content, for example, into chapters, sections, paragraphs.

(2) All logical objects and associated content portions representing the logical hierarchy of a document.

3.114 **Logical structure editing process**

The process that creates a new specific logical structure or modifies a previous specific logical structure and allocates or re-allocates content to basic logical objects.

3.115 **Mandatory attribute**

An attribute which, when applicable to a constituent, must be specified explicitly in that constituent.

3.116 **Nominal page**

A rectangular area which, as assumed by the sender of a document, has the ideal size of the presentation surface.

*NOTE 1–12 Example of ideal sizes are given in ISO 216.*

3.117 **Non-basic**

A qualifier for attribute values, control function parameter values and other capabilities that are only allowed in document interchange in the context of a given document application profile if their use is declared in the document profile.

3.118 **Non-mandatory attribute**

An attribute which, when applicable to a constituent, need not be specified explicitly; if the attribute is not specified explicitly in a given constituent, the attribute does not apply.

3.119 **Object**

An element of the specific layout structure or of the specific logical structure.
3.120 Object class
An element of a generic structure from which objects with common characteristics may be derived.

3.121 Object class description
A set of attributes that specify the properties of an object class including its relationships, if any, with other components.

3.122 Object description
A set of attributes that specify the properties of an object including its relationships, if any, with other components.

3.123 Object type
A property of every component that specifies which attributes are permitted in the description to which it applies and indicates the role of the component in the document architecture.

3.124 Office Document Language; ODL (abbreviation)

3.125 Orphan
One or more lines of text that is associated with subsequent text but isolated from it by a page or column boundary.

3.126 Overhang
The result of a layout or imaging process that positions the sequence of character images for a line to begin at a distance from the line home position in the direction opposite to the character path.

3.127 Page
A layout component that corresponds to a rectangular area used for presenting the content of the document.

3.128 Page coordinate system
An orthogonal coordinate system whose origin is the top left corner of the page; its horizontal axis and its vertical axis coincide with the top edge and the left edge of the page, respectively.

3.129 Page set
A composite layout component that represents a collection of pages or further page sets.

3.130 Pairwise kerning
The distance between two adjacent character images depending on the combination of the two characters together rather than separately.

3.131 Parallel annotation
Two sequential character strings that are presented in parallel, wherein the second string is used to indicate the pronunciation or interpretation of the first string.

3.132 Partial generator set
A collection consisting of hierarchically related object class descriptions which are used to guide the creation of hierarchically related corresponding object descriptions but does not fully specify all specific structures that may be created.

3.133 Pel array
A two-dimensional array of pels used to represent a pictorial image.

3.134 Pel path
The direction of progression of successive pels along a line within a basic layout object.
3.135 **Pel spacing**
The distance between any two successive pels along a line within a basic layout object.

3.136 **Picture element; pel (abbreviation)**
The smallest graphic element that can be individually addressed within a picture; (an alternative term for raster graphics element).

3.137 **Positioning area**
The rectangular area within a basic layout object within which the position points and the escapement points of all character images are located.

3.138 **Position point**
The point relative to which the character image is placed i.e. the character is imaged with the position point at the active position.

3.139 **Presentation**
The operation of rendering a document in a form perceptible to a human being.

3.140 **Presentation medium**
The carrier of information in a form perceptible to a human being.

3.141 **Presentation style**
A constituent of the document, referred to from a basic logical or layout component, which guides the format and appearance of the document content.

3.142 **Presentation surface**
A two–dimensional presentation medium (such as paper, film, video display screen) on which the formatted form of a document may be displayed for human viewing.

3.143 **Processable form**
A form of representation of a document that allows editing and formatting.

3.144 **Processing**
The carrying out of operations on a document, including editing, reformatting, presentation, filing and retrieval.

3.145 **Raster graphics element**
An alternative term for a picture element (pel).

3.146 **Reference area**
A rectangular area within a basic layout object, with its sides equal to the pel spacing and the line spacing, within which the main part of a pel is imaged.

3.147 **Reference line**
A line through the line home position and parallel to the character path.

3.148 **Reference point**
The point at the corner of the reference area situated in the opposite direction of both pel path and line progression and which is used for positioning a pel.

3.149 **Reformatting**
The carrying out of operations to determine the new layout of a previously formatted document.
3.150 **Region of interest**
A rectangular area within a virtual coordinate space, with sides which are parallel to the axes of its coordinate system, surrounding those (parts of) geometric graphics that are intended to be imaged.

3.151 **Resource document**
A generic-document containing one or more object class descriptions referred to by one or more object class descriptions of another document.

3.152 **Retrieval**
The recovery of previously filed information.

3.153 **Right hand edge**
The edge of a frame or block that is parallel to the direction of the layout path and that is met first, from the outside of the frame or the block, in the direction at an angle of 90° counterclockwise relative to the direction of the layout path.

3.154 **Scaled measurement unit ; SMU (abbreviation)**
A unit of linear measurement used for positioning and dimensioning layout objects and content elements on a presentation surface, its value being equal to the basic measurement unit (BMU) times the unit scaling.

3.155 **Sequential layout order**
The sequential order in which layout objects are to be imaged when an imaging order is not specified.

3.156 **Sequential logical order**
The sequential order in which logical objects are to be processed by the layout process.

3.157 **Sequential order**
A convention for ordering the objects in a structure such that each object is succeeded by all of its immediate subordinates, before any other object with the same immediate superior, i.e. in order tree traversal.

3.158 **Soft line terminator**
A line terminator that is allowed to be removed, relocated or replaced in a subsequent layout process.

3.159 **Spacing ratio**
The ratio of line spacing to pel spacing.

3.160 **Specific layout structure**
A set of layout objects and associated content portions.

3.161 **Specific logical structure**
A set of logical objects and associated content portions.

3.162 **Start-aligned**
1. The result of a layout or imaging process that positions the sequence of character images for a line such that the position point of the first character image of that sequence is positioned on the line home position or at the point specified by the first line indentation or overhang if any.
2. A tabulation alignment that positions the sequence of character images for a specified character string such that the position point of the first character image of that sequence is positioned at the tabulation stop.
3.163 **Start edge**
The edge of the positioning area of a basic layout object that is in the direction opposite to the character path.

3.164 **Structural element**
The structural elements of a document are the content portion, the object and the object class.

3.165 **Tabulation alignment**
A layout or imaging process that causes the sequence of character images for a specified character string to be positioned according to a specified method, (start-aligned, end-aligned, centred or aligned-around) at a specified point (tabulation stop) along a reference line.

3.166 **Tabulation stop**
A position along a reference line that is to be used for a specified method (start-aligned, end-aligned, centred or aligned-around) of tabulation alignment.

3.167 **Text unit**
A data structure representing a content portion description.

3.168 **Top edge**
The edge of the positioning area of a basic layout object that is in the direction opposite to the line progression.

3.169 **Top left corner**
The corner of a layout object that is least progressed both in the horizontal and vertical directions of this layout object.

3.170 **Top right corner**
The corner of a layout object that is most progressed in the horizontal direction and least progressed in the vertical direction of this layout object.

3.171 **Trailing edge**
The edge of a frame or block that is orthogonal to the direction of the layout path and that is met first, from the outside of the frame or the block, in the direction of the layout path.

3.172 **Unit scaling**
A scaling factor (an integer or a fraction) that is applied to the basic measurement unit (BMU) to derive a scaled measurement unit (SMU).

3.173 **Variable spacing**
The characteristics of a font wherein the distance between the position point and the escapement point for different character images may be different.

3.174 **Widow**
One or more lines of text associated with preceding text but isolated from it by a page or column boundary.

4. **CONVENTIONS**
The following conventions are used throughout this standard.

4.1 **Names of attributes**
The names of attributes are referenced by giving the name of the attribute in double quotation marks preceded by the word attribute. For example:
"...expressed by the attribute “subordinates”. This attribute..."
In some cases terms are used to describe concepts which have the same name as an attribute. In the case of reference to such concepts neither the word attribute nor quotes are used.
4.2 Names of attribute values
The names of attribute values are referenced by giving the name of the attribute value in single quotation marks. For example:

"...the second parameter allows a sender to select a recto or a verso presentation of the page by specifying the value ‘recto’ or ‘verso’, respectively."

4.3 Component and component description
The term component may be used in conjunction with qualifying terms, including: basic, composite, page set, page, frame, block, logical and layout. For example:

a) “layout components containing blocks” means “layout objects containing blocks, or classes of layout objects containing blocks”;

b) “frame component” means “an object of type frame, or a class from which objects of type frame may be derived”.

The term component description may be qualified the same way.

4.4 Introduction of terms
For the purpose of highlighting the point at which the definition of a term occurs in the text the term is represented in bold. These terms are also defined in clause 3.

5. GENERAL CONCEPT OF ODA

5.1 Purpose of ODA
The purpose of the document architecture is to facilitate the interchange of documents in a manner such that

- different types of content, including text, image, graphic and sound, can coexist within a document;
- the intentions of a document originator with respect to editing, formatting and presentation can be communicated most effectively.

This clause uses a number of terms for which definitions are given in clause 3. However, for the purpose of the current clause, different though compatible definitions of the essential terms are given below.

- Interchange is the process of providing a document to a receiving person or device, by means of data communication or by exchange of storage media.
- Editing is the carrying out of operations associated with creation and amendment of the structure and/or the content of a document.
- Formatting is the carrying out of operations to determine the layout of a document, i.e. the appearance of its content on a presentation medium.
- Presentation is the operation of rendering the content of a document in a form perceptible to a human being. Typical presentation media are paper and video screens.

The document architecture provides for the representation of documents in three form

- formatted form, that allows documents to be presented as intended by the originator;
- processable form, that allows documents to be edited and formatted;
- formatted processable form, that allows documents to be presented as well as edited and reformatted;

Alternative terms commonly used are “final form” and “image form” for “formatted form”, and “revisable form” for “processable form”.

Each of these forms allows the originator to express intentions regarding the structuring and/or formatting of the interchanged document.

5.2 Overall concept of ODA
The concept of ODA is based on

- the existence of a layout view and a logical view of the document; the view from the physical viewpoint (for example, a collection of pages) and the view in the sense of its abstract components (for example, an assembly of sentences);
the existence of a specific structure and a generic structure; the specific “document” structure is the one that the user may read; the generic structure is the template that guides the creation of the document and that could be re-used for its amendment;

the existence of document classes: a document class is the set of generic features that are common to a category of documents (for example, Sales Report Form).

5.2.1 Logical structure and layout structure

The key concept in the document architecture is that of structure. Document structure is the division and repeated subdivision of the content of a document into increasingly smaller parts. The parts are called objects. The structure has the form of a tree.

The document architecture permits two structures to be applied to a document: a logical structure and a layout structure. Any one or both structures may be applied to a given document.

In the logical structure, the document is divided and subdivided on the basis of the meaning. Examples of logical objects are chapters, sections, figures and paragraphs.

In the layout structure, the document is divided and subdivided on the basis of the layout. Examples of layout objects are pages and blocks.

An example of the logical view of a document called “report” is shown in figure 1–1.

Figure 1–1 – Example of a logical view of a document

The logical structure and the layout structure provide alternative but complementary views of the same document. For example, a book can be regarded as consisting of chapters containing figures and paragraphs, or alternatively, as consisting of pages that contain text blocks and/or graphic blocks.
An object that is not subdivided into smaller objects is called a basic object. All other objects are called composite objects.

The following types of layout objects are defined in the document architecture:

- block: a basic layout object corresponding to a rectangular area on the presentation medium containing a portion of the document content;
- frame: a composite layout object corresponding to a rectangular area on the presentation medium and containing either one or more frames or one or more blocks;
- page: a basic or composite layout object corresponding to a rectangular area on the presentation medium and, if it is a composite object, containing either one or more frames or one or more blocks;
- page set: a set of one or more page sets and/or pages;
- document layout root: the highest level object in the hierarchy of the specific layout structure.

For logical objects, no classification other than “basic logical object”, “composite logical object” and “document logical root” is defined in the document architecture. Logical object categories such as “chapter”, “section” and “paragraph” are application-dependent and can be defined using the “object class” mechanism (see 5.2.6).

5.2.2 Content portions

The basic elements of the content of a document are called content elements. For content consisting of character text, the content elements are characters. In the case of images or graphics, the content elements are picture elements (also called pels) or geometric graphics elements (lines, arcs, polygons, etc.).

When a document has both logical structure and layout structure, each content element belongs, in general, to exactly one basic logical object and to exactly one basic layout object. A set of related content elements that belong to one basic logical object (if the document has any logical structure) and one basic layout object (if the document has any layout structure) is called a content portion.

It follows from this description that

- a basic logical object has associated with it one or more content portions;
- a basic layout object has associated with it one or more content portions;
- any logical or layout object (basic or composite) has associated with it an integral number of content portions;
- there is, in general, no one-to-one correspondence between logical objects and layout objects.

The last point is illustrated by figure 1–2.
5.2.3 Content architectures

A content portion associated with a basic logical object or a basic layout object may have a more detailed internal structure. The rules governing such an internal structure depend on the type of content and are called a content architecture. The content of a basic logical object or a basic layout object is structured according to only one content architecture.

Parts 6, 7 and 8 of this standard contain definitions of content architectures for characters, raster graphics and geometric graphics respectively.

5.2.4 Attributes

An attribute is a property of a document, or of a document constituent (i.e. a logical object, a layout object, a logical object class, a layout object class, a style or a content portion). It expresses a characteristic of the document or document component concerned, or a relationship with one or more documents or document components.

The set of attributes associated with a document as a whole is called document profile. It represents reference information about the document and may repeat information in the document content, for example, the title and the name of the author.

The set of attributes that applies to a logical object or a layout object depends on the type of the object: different sets of attributes are defined for basic logical objects, composite logical objects, document logical root, blocks, frames, pages, page sets and document layout root. These are called document architecture attributes. Document architecture attributes are independent of the type of content of the objects to which they apply.

Examples of document architecture attributes are

- the attribute “object identifier” (all objects);
- the attribute “subordinates” (composite objects);
- layout directives such as the attribute “indivisibility”, the attribute “offset”, the attribute “separation”;
the attribute “position” (blocks and frames); – the attribute “dimensions” (blocks, frames and pages).

In addition to the document architecture attributes, a set of presentation attributes applies to basic logical and basic layout objects. The set of presentation attributes that applies to a given basic object depends on the content architecture governing the content of this object: a different set of presentation attributes is defined for each content architecture.

Examples of presentation attributes are

– the attribute “line spacing” (character content architectures);
– the attribute “clipping” (raster graphics content architectures);
– the attribute “line rendition” (geometric graphics content architectures).

Presentation attributes may be collected into presentation styles, to which references may be made from both logical and layout objects. The attributes that apply to a content portion include a content portion identifier and a set of coding attributes, the composition of which depends on the coding method used for the content, for example, the attribute “number of pels per line” for facsimile-coded raster graphics images.

5.2.5 Relations between logical structure and layout structure

The logical structure and the layout structure are, in principle, independent of each other. The logical structure of a document is determined by the author and embedded in the document during the editing process. The layout structure is usually determined by a formatting process. The formatting process may be controlled by attributes called layout directives associated with the logical structure.

Examples of layout directives are

– the requirement that a chapter starts on a new page;
– the requirement that the title of a section and the first two lines of its first paragraph are presented on the same page;
– the amount of indentation for a list of items. Layout directives may be collected into layout styles each of which may be referred to by one or more logical objects.

5.2.6 Specific and generic structures

In a document, the logical objects and/or the layout objects can often be classified into groups of similar objects. Therefore the concept of object class is introduced.

The similarity may be related to logical features such as chapter, section or paragraph hierarchy, to layout features such as size or style, or to content such as page headers and footers. Even an entire document may be a member of a group of similar documents, a letter, a memorandum or a report. An object class or a document class is a specification of the set of properties that are common to its members. Such a specification consists of a set of rules to determine the values of the attributes that specify the common properties. These rules can be used to control the consistency among the objects or documents making up the class, and to facilitate the creation of additional objects or documents within the class.

The set of logical object classes and layout object classes associated with a document, and their relationships, are called generic logical structure and generic layout structure.

The structures that are particular to a given document are named specific logical structure and specific layout structure.

A document class is described by a generic logical structure and a generic layout structure.

The generic logical structure represents the set of all potential specific logical structures, and the generic layout structure represents the set of all potential specific layout structures that are applicable to the document class concerned.

The generic logical structure can be used as a set of rules from which specific logical objects and structures are derived during the editing process. The generic layout structure can be used as a set of rules from which specific layout objects and structures are derived during the formatting process.

An example of generic layout structure is depicted by figure 1–3 which shows a page layout with frames for a header, a footer and two columns of body text.
5.2.7 Document profile

The document profile consists of a set of attributes associated with a document as a whole. In addition to reference information such as title, date and author’s name, which facilitates storage and retrieval of the document, the document profile contains a summary of the document architecture features that are used in the document, in order that a recipient can easily determine which capabilities are required for processing or imaging the document. The attributes representing the latter type of information are called document characteristics and include:

- a specification of the form (formatted, processable or formatted processable) of the document;
- specifications of the content architectures used in the document;
- specifications of the character sets, character fonts, character styles, character orientations and types of emphasis used in the document.

The document profile may be interchanged alone.

5.2.8 Generic-document

A generic-document consisting of a document profile and generic structures can be used to assist in the processing of interchanged documents. A generic-document may be interchanged.

5.3 Document processing model

5.3.1 Relationships of ODA to document processing

This Standard is concerned with the definition of a document architecture which permits processing of interchanged documents. A model of document processing is provided as a basis for determining the scope of the processes described by this Standard.

A basic model of document processing is summarized in this subclause (see figure 1-4). This model is not intended to represent an actual implementation, nor to restrict in any way the processing that may be applied to an interchanged document.
Conceptually, a document is viewed as progressing through three phases of processing as shown in figure 1-4. The order of the processes is not intended to imply that they are performed sequentially in an actual implementation.

5.3.2 Editing process
The document editing process is concerned with creating a new document or modifying a previous one. The document architecture provides data structures for representing the document resulting from this process and for representing control information which influences this process.

While document creation and modification may differ in the functions performed and procedures followed, they are considered to be equivalent in the view of this model because the result of both is the same: a new document.

Upon completion of editing, the resulting document can be interchanged. Such a document is said to be interchanged in "processable" form; it is suitable for input to either the editing or layout process.

5.3.3 Layout process
The document layout process is concerned with defining a page-oriented organization (i.e. a layout) for the document content. This process can operate in two ways.

The layout process can generate a document which is not intended to be modified; it is suitable only for input to the imaging process. Such a document is said to be in "formatted" form.

This process can also generate a "formatted processable" form document which can be processed further if desired; it is suitable for input to any of the imaging, layout or editing processes.

The document architecture provides data structures for representing both forms of formatted documents and for representing control information which influences the layout process.

5.3.4 Imaging process
The document imaging process is concerned with presenting an image of the document in a form perceptible to a human, for example, on paper or on a screen. A document interchanged in accordance with this Standard may contain information relating to the imaging process which allows it to be imaged as required by the originator of the document. However, the imaging process is not defined by this Standard and is regarded as a locally defined process that depends on the presentation device used.

Other forms of document processing may be possible; these are not specifically addressed by the document architecture.
6. OVERVIEW OF THE PARTS
Parts of this Standard are numbered 1, 2 and 4 through 8. At present, there is no part 3.

6.1 Part 1: Introduction and general principles
Part 1 of this Standard provides information about this standard as a whole by way of an introductory description of the document architecture, an overview of each of the parts and a description of their inter-dependencies. References necessary for all parts are given, and terms used throughout all parts are defined. Conformance to this Standard is specified and rules for defining document application profiles are given.

6.2 Part 2: Document structures
Part 2 of this Standard defines document architecture concepts which can be applied to the description of representations of documents. The purpose is to permit a common understanding of the structure of a document. The term “document architecture” is used to mean a set of rules by which a document can be produced or interpreted.

Part 2 of this Standard describes the architectural concepts and defines the document structures and attributes. It specifies the interface between the document architecture and the content architectures, and defines the document architecture classes. A description of the document processing model is provided. In addition, examples of document structures based on this Standard and a suggested notation for representing them are included.

6.3 Part 4: Document profile
Part 4 of this Standard defines the document profile that provides information concerning the handling of the document. This is accomplished by means of attributes, (for example, title, author(s)), a few of which apply to the representation of the document profile itself. Some relate to the processing of the document (for example, filing/retrieval, other applications). Other attributes provide a means for a user to specify user-specific information (for example, organization, status). Some of the information given in the document profile could duplicate that in the body of the document.

The document profile may be interchanged alone, that is without the remainder of the document constituents.
NOTE 1–13
Information contained in the document profile is intended for a recipient (person) and/or device (for example, keywords). Some attribute values may have been supplied automatically (for example, size).

6.4 Part 5: Open document interchange format (ODIF)
Part 5 of this Standard defines the format of the data stream used to interchange open documents structured in accordance with part 2.
The ODIF data stream is described in terms of a set of data structures, called “interchange data element”, which represent the constituents (document profile, object descriptions, object class descriptions, presentation styles, layout styles and content portion descriptions) of a document. The formats of the interchanged data element according to ODIF are defined using the Abstract Syntax Notation One (ASN.1) specified in ISO 8824.

6.5 Part 6: Character content architectures
Part 6 of this Standard applies to documents that are structured according to the architecture defined in part 2 and that include character content, consisting of a combination of graphic characters, control functions and space characters.
For this type of content architecture it defines those aspects of positioning and imaging that are applicable to the presentation of character content. It also defines specific character content architecture classes in terms of their structure, attributes, character repertoires, control functions and coding.

6.6 Part 7: Raster graphics content architectures
Part 7 of this Standard applies to documents that are structured according to the architecture defined in part 2 that include raster graphics content, consisting of a descriptive representation of pictorial information provided by an array of picture elements (pels), encoded according to facsimile or bitmap encoding.
For this type of content architecture, it defines those aspects of positioning and imaging that are applicable to the presentation of raster graphics content. It also defines each class of raster graphics content architecture in terms of its structure, presentation attributes, content layout process, control functions and coding attributes.

6.7 Part 8: Geometric graphics content architectures
Part 8 of this Standard applies to documents that are structured according to the architecture defined in part 2 that include geometric graphics content, consisting of a descriptive representation of picture description information as an ordered set of elements such as lines, arcs, polygons, attributes for these drawing elements, elements that structure the content portion, etc. using the Computer Graphic Metafile (CGM) and its binary encoding defined in ISO 8632–1 and ISO 8632–3, respectively.
For this type of content architecture, it defines those aspects of positioning and imaging that are applicable to the presentation of geometric graphics content. It also defines the geometric graphics content architecture class in terms of its structure, presentation attributes, the relevant CGM parameters, the content layout process, control functions and coding attributes.

7. INTER-DEPENDENCIES OF THE PARTS
If there is a requirement to interchange documents or generic documents, it is necessary to use parts 1, 2, 4 and 5 together:
- Part 1 Introduction and general principles;
- Part 2 Document structures;
- Part 4 Document profile;
- Part 5 Open document interchange format (ODIF).
Should there be a requirement to interchange just the document profile, then only parts 1, 4 and 5 are necessary.
Additionally, it will be necessary to use one or more of the remaining parts, depending on the particular type of content to be interchanged, for example:
8. CONFORMANCE
The conformance to this Standard is defined in terms of conformance of a data stream that represents a document, a generic-document or a document profile. For the definition of conformance it is necessary to distinguish two cases:

- the document profile attribute "document application profile" is the identifier of a document application profile;
- no value is specified for the document profile attribute "document application profile".

A document application profile can only be specified if it is identified by an ASN.1 object identifier. This includes document application profiles defined in International Standards or CCITT Recommendations, or registered by registration authorities; see annexes B, C and D of ISO 8824.

When the attribute "document application profile" is present in the document profile of a given document or generic-document, the data stream representing this document or generic-document is in conformance with this Standard if it conforms to the specified document application profile.

In the absence of the specification of a document application profile, the data stream representing the document or generic-document shall be assumed to conform to parts 1, 2, 4, 5, 6, 7 and 8 of this Standard. This means that the document or generic-document may contain

a) any of the document architecture classes defined in part 2 of this Standard, any attribute and attribute value permitted for that class;
b) any content architecture class which is defined in parts 6, 7 and 8 of this Standard that defines such classes and any presentation attribute, control function, coding attribute and graphic element permitted for that class;
c) any document profile attribute defined in part 4 of this Standard;
d) any one of the interchange format classes as defined in part 5 of this Standard;
e) no content architecture classes other than those defined in parts 6, 7 and 8;
f) only graphic character sets specified by other Standards or CCITT Recommendations;
g) only geometric graphic elements specified by ISO 8632–1 and parameter values of these elements defined in ISO 8632–1 and ISO 8632–3 for these elements.

9. DOCUMENT APPLICATION PROFILE
A document application profile is the specification of a combination of features that are defined in various parts of this Standard. It is identified by a unique ASN.1 object identifier obtained in accordance with the rules in ISO 8824.

In order to define a valid combination, the features shall be selected according to the rules given in 9.2:
- Features pertaining to a document architecture class are selected to form a document architecture level.
- Features of a content architecture class are selected to form a content architecture level.
- Features of the document profile are selected to constitute a document profile level.
- An interchange format class is selected.

A document application profile must include
- one or more document architecture levels;
- one or more content architecture levels;
- a document profile level;
- an interchange format class.

The document architecture features can be broken down into

a) three classes:
   - formatted document architecture (FDA),
   - processable document architecture (PDA),
   - formatted processable document architecture (FPDA);
b) for each class its
   - constituents;
c) for each constituent its
   - attributes;

d) for each attribute its
   - classification (mandatory, non-mandatory, defaultable);
   - permissible values divided into basic, non-basic values;
   - default value, if the attribute is defaultable.

The content architecture features depend primarily on the type of content. For each type of content, various content architecture classes exist (for example, for character content architectures the classes are: character formatted, character processable, and character formatted processable);

e) for each content architecture class are defined its
   - presentation attributes,
   - coding attributes,
   - control functions;

f) for each presentation attribute, coding attribute and control function parameter its
   - permissible values divided into basic, non-basic values;
   - default value.

The features of the document profile are its

g) attributes;

h) for each attribute its
   - classification (mandatory, non-mandatory),
   - permissible values.

The interchange formats that are permitted by this Standard are

i) the open document interchange format (ODIF) divided into
   - class A
   - class B

9.1 General principles for defining a document application profile

A document application profile can only place constraints on the previously listed features, it cannot extend them.

A document application profile shall not allow the use of attributes for purposes beyond those defined in this Standard. That is, a document application profile shall not modify in any way the semantics of the attributes defined in this Standard.

9.2 Rules for defining a document application profile

The rules for defining a document application profile consist of rules for defining document architecture levels, content architecture levels, a document profile level and for selecting an interchange format class.

9.2.1 Rules for defining a document architecture level

Part 2 of this Standard specifies the three document architecture classes that may be used in defining document architecture levels. These are formatted document architecture class, processable document architecture class and formatted processable document architecture class.

For each of these classes, part 2 of this Standard defines which document structures may be used in documents that pertain to that class. These structures are classified as mandatory or optional. Each class also specifies which objects and object classes are applicable to these structures and, again, objects are classified as mandatory or optional. The class also defines which attributes are applicable to those objects and object classes and the body of part 2 of this Standard defines all permissible values and a standard default value for each defaultable attribute.

A document architecture level defines restrictions concerning which structures, objects and object classes, attributes and attribute values are allowed to be contained in documents or generic-documents that pertain to that level.

NOTE 1-14
The term “superclass” is sometimes applied to the set of document classes or object classes whose
hierarchy of subordinate object classes and associated attributes and attribute values is restricted by a document application profile.

For each document architecture class, only one document architecture level can be specified. For example, a document application profile cannot make use of two different document architecture levels pertaining to the processable document architecture class (PDA).

The rules for defining a document architecture level are given below.

a) The document architecture level shall pertain to a particular document architecture class, that is, the level shall make use of only those document structures, objects and object classes that pertain to the specified document architecture class.

b) The document architecture level shall specify which document structures pertain to that level. Structures pertaining to the corresponding document architecture class that are mandatory shall be specified as mandatory in the document architecture level. Structures specified as optional in the document architecture class may be specified as optional or mandatory in the document architecture level.

NOTE 1–15
If a factor set or a partial generator set is used, then the document architecture level should, in general, specify this as optional.

c) When a document application profile allows the interchange of more than one document architecture class (for example, formatted, processable and formatted processable), the document architecture levels shall be consistent. For example, the generic logical structure used in the document architecture level of processable form shall be identical to that used in the document architecture level of formatted processable form.

d) The document architecture level shall specify which objects and object classes pertain to that level. Objects and object classes that are mandatory for a particular structure shall be specified as mandatory in the document architecture level. Objects and object classes that are specified as optional may be specified as optional or mandatory in the document architecture level.

e) The document architecture level shall specify any restrictions that are applicable to the document structures that belong to the level. For example, the number of hierarchical levels allowed in a particular structure may be restricted or the specific structures allowed may be required to pertain to certain defined document classes.

f) The document architecture level shall specify, in the case of formatted document architecture class, whether the pages are to be composite or basic.

g) The document architecture level shall specify, in the case of formatted or processable document architecture classes, whether only one content portion or multiple content portions can be associated with basic objects.

h) For each object or object class used, the document architecture level shall specify which attributes are applicable. These shall include the appropriate minimum set of attributes pertaining to each object type as defined in part 2 of this Standard.

i) For each permitted attribute, the document architecture level shall specify the basic, default and non–basic (if any) values that are applicable. These values shall be taken from the range of permissible values specified in the attribute definitions in part 2 of this Standard.

NOTE 1–16
It is recommended that the default value used for defaultable attributes is that specified in the corresponding document architecture class.

j) The document architecture level may classify attributes that are designated as being defaultable or non–mandatory in part 2 of this Standard as being mandatory for that level. The classification of mandatory attributes shall not be changed.

k) The document architecture level shall specify which attributes may be included in the attribute “default value lists” and must specify the object types for which a default value list can be specified. part 2 of this Standard gives a definition of the use of this attribute.

9.2.2 Rules for defining a content architecture level

Each part of this Standard that caters for particular content types defines one or more than one content architecture class that corresponds to that content type. The number of content architecture classes defined depend upon the particular content type.

Each content architecture class definition consists of the specification of the following:
- a set of presentation attributes;
- a set of content elements;
- a set of control functions;
- the type(s) of coding used;
- a set of coding attributes.

For each presentation attribute and coding attribute, the content architecture class definition specifies the permissible values and a recommended default value. Similarly, the content architecture class definition specifies the permissible values and a recommended default value for the control function parameters (where applicable).

Each content architecture class definition also specifies the basic component types that the content architecture class can be used in.

A content architecture level defines restrictions concerning which presentation attributes, control functions and coding attributes, and their values, are allowed to be used in association with content pertaining to that level. The content architecture level may also define restrictions concerning the content elements and types of coding that may be used.

For each content architecture class, that is defined for a particular type of content, only one content architecture level can be specified. For example, a document application profile cannot make use of two different content architecture levels pertaining to the formatted character content architecture class (CF).

The rules for defining a content architecture level are given below.

a) The content architecture level shall pertain to a particular content architecture class, that is, the presentation attributes, content elements, control functions, types of coding and coding attributes specified by the content architecture shall be taken from those specified in the corresponding content architecture class.

b) When a document application profile allows the interchange of more than one content architecture class pertaining to the same content type (for example, formatted, processable and formatted processable for character content architecture classes), the levels shall be consistent. For example the features used in the content architecture level of formatted form shall be, when applicable, identical to those used in the content architecture level of formatted processable form.

c) Subject to the above restrictions, there is no further restriction on which presentation attributes, content elements, control functions, type of coding and coding attributes can be specified in a content architecture level.

d) The content architecture level shall specify, for each permitted presentation attribute, control function and coding attribute, the basic, default and non-basic (if any) values that are applicable. These values shall be taken from the range of permissible values specified in the corresponding content architecture class.

NOTE I–17
It is recommended that the default value used is that specified in the content architecture class.

e) The content architecture level shall specify which set or sets of content elements are applicable. These shall be taken from the permissible sets specified in the corresponding content architecture class. If appropriate, a default set of content elements may be specified. In addition, a distinction may be made between basic and non-basic content elements. The type or types of coding allowable shall also be specified.

NOTE I–18
There may be mandatory content elements (for example, BEGIN METAFILE or END METAFILE in the case of geometric graphics content type) that are to be present in every set of content elements specified by a content architecture level.

This Standard allows the interchange of documents containing content architecture levels pertaining to content architecture classes that are not defined in this Standard. This Standard does not define how such content architecture levels should be specified except that the interface between the content architecture and the document architecture should be defined as specified in part 2 of this Standard. The only restriction imposed on the use of content architecture levels defined outside of this Standard is that they are not allowed to be used if no document application profile identifier is indicated in the document profile (see clause 8).
9.2.3 Rules for defining a document profile level

Part 4 of this Standard defines all attributes that may be specified for use in a document profile. The rules for specifying how document profile attributes may be used in a document profile level are given below.

a) The document profile level may specify any document profile attribute defined in part 4 of this Standard. It shall not specify attributes not defined in part 4 of this Standard.

b) The document profile level shall specify the minimum set of document profile attributes defined in part 4 of this Standard appendix B.

c) The document profile level may specify any document profile attribute as being mandatory or non-mandatory for that level.

d) The document profile level shall specify attribute values taken from the range of permissible values defined in part 4 of this Standard.

e) The document profile level may specify additional restriction on the use of certain attributes and limit the values applicable to these attributes.

f) The document profile level shall not modify the semantics of the absence of attributes from those semantics specified in part 4 of this Standard.

9.2.4 Rules for selecting the interchange format class

Part 5 of this Standard defines the valid interchange format classes that can be used for interchanging a document or a generic-document. It also defines the restrictions on the use of these interchange format classes. Only one interchange format class may be specified in a document application profile. No other restriction may be specified concerning the use of an interchange format class in a document application profile.

NOTE 1–19
This requirement does not preclude applications in mixed office and publishing environment, in which documents could be interchanged using class A, class B or SDIF. Such interchange is effected by defining two document application profiles that differ only in their interchange format class; for example, by creating a single specification document with individual ASN.1 object identifiers for class A and SDIF interchange.
APPENDIX A

References to other standards and registers

(This Appendix is not part of the Standard)

The following standards are given for information. They are not required for the application of this Standard.
ISO 216 : 1975, "Writing paper and certain classes of printed matter – Trimmed sizes – A and B series”;
ISO 2375 : 1985, "Data processing – Procedure for registration of escape sequences”;
ISO 7350 : 1984, "Text communication – Registration of graphic character subrepertoires”;
"ISO International register of character sets to be used with escape sequences”;
"ISO International register of graphic character subrepertoires”.
ANSI X3.151 : 1987, "Bond papers and index bristols – Basic sheet sizes and standard stock sizes”;
JIS P 0138 : 1961, "Trimmed sizes of paper”;
CCITT Recommendation T.61 : 1984, "Character repertoire and coded character sets for the international Teletex service”;
CCITT Recommendation T.73 : 1984, "Document interchange protocol for the telematic services”;
CCITT Recommendation T.400 : 1988, "Introduction to Document Architecture, Transfer and Manipulation”;
Introduction and General Principles”;
Document Structures”;
Document Profile”;
Open Document Interchange Format (ODIF)”;

Geometric Graphics Content Architectures”;
APPENDIX B

Relationship with other standards

(This Appendix is not part of the Standard)

B.1 Transfer standards

Documents structured and represented according to this Standard can be transferred using the functions defined in the following standards and other similar standards.

ISO 10021, Information processing – Text communication – Message Oriented Text Interchange System:
The interchange format defined in this standard constitutes an application context as defined in
The abstract syntax of the application context is defined in part 5 of this Standard.

B.2 Other standards

B.2.1 This Standard has been developed in parallel with the T.410 series of CCITT Recommendations (1988): “Open Document Architecture (ODA) and Interchange Format”.
The text of part 1 of this Standard to part 8 of this Standard are identical to the texts in the correspondingly numbered CCITT Recommendations T.411 to T.418 except for mandated stylistic differences and provisions of this Standard that are outside the scope of these Recommendations.

B.2.2 Provision has been made in this Standard for compatibility with CCITT Recommendation T.73 : 1984, Document transfer protocol for the telematic services, by providing for a specific document interchange format class B, and by the provision of a number of structures and attributes primarily intended for use in document interchange format class B. These structures and attributes are identified and cross-referenced to the appropriate parts of this Standard in Appendix C.
Whenever interchange format class B is used, with the appropriate document structures and attributes, documents may be exchanged with application contexts conforming to CCITT Recommendation T.73 (1984).
Both the CCITT Recommendation T.73 (1984) and the ECMA-101 application contexts will need to define the interchange by use of identical document application profiles.

B.2.3 This Standard has been developed in parallel with ISO 8613 “Office Document Architecture (ODA) and Interchange Format” (to be published). The text of ECMA-101 is identical to ISO 8613 with the following exceptions:
− the SGML Document Interchange Format is not supported;
− Appendix E of Part 1 is part of the standard in ECMA-101, and not part of the Standard in ISO 8613;
− a number of mandatory editorial changes have been made.
APPENDIX C

Correspondance between CCITT Recommendation T.73 (1984) and this Standard

(This Appendix is not part of the Standard)

CCITT Recommendation T.73 (1984) is replaced by the Recommendations in the T.410 series. This appendix describes the relationships between the CCITT Recommendation T.73 (1984) and this Standard.

C.1 Data stream format
In CCITT Recommendation T.73 (1984) only one interchange data stream is specified, which corresponds to the interchange format class B in part 5 of this Standard.

C.2 Presentation capabilities descriptor

C.3 Attributes
Several attributes and attribute values have different names in CCITT Recommendation T.73 (1984) and in this Standard.
Table 1–C–1 lists all attributes of CCITT Recommendation T.73 (1984) along with their locations together with the corresponding names and locations in the parts of this Standard. CCITT Recommendation T.73 (1984) is replaced by the Recommendations in the T.410 series. This annex describes the relationships between CCITT Recommendation T.73 (1984) and this Standard.

Appendix D

Principles for the assignment of ASN.1 object identifier values

(This Appendix is not part of the Standard)

Values of ASN.1 object identifiers are assigned in various parts of this Standard. The assignment of these values is based on the following principles:

a) the value of the first component is 2, representing “joint-iso-ccitt”;

b) the value of the second component is 8, designating the area of joint ISO-CCITT work “document architecture”;

c) the value of the third component is 0, 1, 2 or 3, identifying one of the following categories of object identifier values assigned within this area of work:

   0 – object identifier value to be used as a part of an ASN.1 external data type;
   1 – object identifier value to be used as a part of an ASN.1 module identifier;
   2 – object identifier value for the identification of a content architecture class;
   3 – object identifier value for the identification of a type of coding;

d) the meaning of the fourth component and that of the fifth component, if any, depends on the value of the third component as follows:

   - if the value of the third component is 0, the fourth component identifies a particular external data type; values of the fourth component are assigned in part 5 of this Standard; in this case, there is no fifth component;
   - if the third component is 1, 2 or 3, the fourth component identifies the part of this Standard in which the value of the fifth component is assigned:

   5 – part 5 of this Standard;
   6 – part 6 of this Standard;
   7 – part 7 of this Standard;
   8 – part 8 of this Standard.
Appendix E

Information on CCITT Recommendation T.411 – Annex E

The text of annex E of CCITT Recommendation T.411 is presented hereafter for information.

Annex E
(to CCITT Recommendation T.411)
(Normative)
Use of MHS to Interchange Documents Conforming
to the T.410 series of Recommendations

E.1 ODA Identification in the P1 Protocol of MHS:
Documents shall be identified by a set of ASN.1 object identifiers as externally-defined encoded-information-types. One member shall always be the ASN.1 object identifier for ODA, the other members shall be one or more ASN.1 object identifiers for the document application profiles to which the message body parts conform.

ODA document
Document Application Profile { 2 8 0 0 }
{ CCITT recommendation TXXX Y }
{ ................................................... }
{ ................................................... }

Note 1 – Documents conforming to ODA shall not be converted
Note 2 – These Document Application Profiles are those defined for CCITT. Other organizations shall use object identifiers as appropriate.

E.2 ODA Identification in the P2 Protocol of MHS
Documents conforming to ODA shall be identified as ODA extended body parts. Each extended body part shall contain parameter information about the applicable document application profile and the document architecture class.

Note – ODA body parts can be mixed with non–ODA body parts in a P2 Body.
The module for specifying the ODA Body Parts is described in the following page:

1) Message Handling Services (MHS) are described in the X.400 series of Recommendations.

Standard ECMA–101 – Open Document Architecture (ODA) and Interchange Format

Part 2 – Document Structures

This second edition of Standard ECMA–101 has been prepared by ECMA/TC29 to align ECMA–101 with the current ISO/CCITT publications.

At present this standard consists of seven parts:
- Part 1, Introduction and General Principles;
- Part 2, Document Structures;
- Part 4, Document Profile;
- Part 5, Open Document Interchange Format (ODIF);
- Part 6, Character Content Architectures;
- Part 7, Raster Graphics Content Architectures;
- Part 8, Geometric Graphics Content Architectures.
At present, there is no part 3.
Further parts may be added to this ECMA Standard.

This part 2 contains six Appendices:
- Appendix A: Notation used for representing Document Structures;
- Appendix B: Examples of Document Structures;
- Appendix C: Examples of Document Architecture Levels;
- Appendix D: Examples of Particular Document Architecture Features;
- Appendix E: The defaulting Mechanism;
- Appendix F: Attribute Summary Tables.
1. INTRODUCTION

1.1 Scope

The purpose of this Standard ECMA-101 is to facilitate the interchange of documents.
In the context of this Standard, documents are considered to be items such as memoranda, letters, invoices, forms and reports, which may include pictures and tabular material. The content elements used within the documents may include graphic characters, geometric graphics elements and raster graphics elements, all potentially within one document.

NOTE 2–1
This Standard is designed to allow for extensions, including typographical features, colour, spreadsheets and additional types of content such as sound.

This Standard applies to the interchange of documents by means of data communications or the exchange of storage media.
It provides for the interchange of documents for either or both of the following purposes:
– to allow presentation as intended by the originator;
– to allow processing, such as editing and reformatting.
The composition of a document in interchange can take several forms:
– formatted form, allowing presentation of the document;
– processable form, allowing processing of the document;
– formatted processable form, allowing both presentation and processing.
This Standard also provides for the interchange of ODA information structures used for the processing of interchanged documents.
Furthermore, this Standard allows for the interchange of documents containing one or more different types of content such as character text, images, graphics and sound.
This part of ECMA-101
– defines a document architecture intended for representation of documents;
– defines a document processing model;
– defines the document structures, the basic constituents of the architecture and a descriptive representation of these in terms of attributes;
– defines an interface which allows the use of different content architectures with the document architecture;
– defines the reference model of the document layout process;
– defines the reference model of the document imaging process;
– defines three document architecture classes;
– defines a notation used for illustrating and describing document structures;
– provides examples of document architecture levels;
– provides examples of document structures;
– provides examples of particular document attributes.

1.2 References

Part 1 – Introduction and general principles;
Part 4 – Document profile
Part 5 – Open document interchange format (ODIF);
Part 6 – Character content architectures;
Part 7 – Raster graphics content architectures;
1.3 Definitions, symbols and abbreviations

1.3.1 Definitions
For the purpose of this part of ECMA-101 the definitions given in part 1 of this Standard apply.

1.3.2 Conventions
The following conventions are used throughout this part of ECMA-101.

1.3.2.1 Subordinate
References to the immediate subordinates of an object always use the form “immediate subordinates” or “immediately subordinate”.
When the term “subordinate” is used without this qualifier it means subordinate to any hierarchical level.

1.3.2.2 Superior
References to the immediate superior of an object always use the form “immediate superior” or “immediately superior”.
The term “nearest superior” is used in conjunction with an object and with a particular qualification to mean the first superior going up the hierarchy which satisfies the qualification, i.e. first checking the immediate superior, then its immediate superior, and then each superior in turn in this hierarchic order. For example, “nearest superior that belongs to the specified object class” means the first superior going up the hierarchy from the object which is of the specified object class.
When the term “superior” is used without either of these qualifiers it means superior to any hierarchical level.

1.3.2.3 Next and Following
When the term “next” or “immediately following” is used in conjunction with an object then it means the object immediately following this object in sequential order (see 3.1.2). Thus, “next layout object” means the immediately following layout object in sequential layout order; “next logical object” means the immediately following logical object in sequential logical order.
When the term “following” is used in conjunction with an object without the qualifier “immediately” then it means an object at any position later in the sequential order than this object.
In some cases the term “next” is used together with a further qualification, for example, “next layout object with the same layout category” means the first of the following layout objects in sequential layout order which has the same layout category as the specified layout object.

1.3.2.4 Preceding
When the term “immediately preceding” is used in conjunction with an object then it means the object immediately preceding this object in sequential order (see 3.1.2). Thus, “immediately preceding layout object” means the immediately preceding layout object in sequential layout order; “immediately preceding logical object” means the immediately preceding logical object in sequential logical order.
When the term “preceding” is used in conjunction with an object without the qualifier “immediately”, then it means an object at any position earlier in sequential order than this object.
In some cases the term “preceding” is used together with a further qualification, for example, “preceding layout object with the same layout category” means the last of the preceding layout objects in sequential layout order which has the same layout category as the specified layout object.
2. ARCHITECTURAL PRINCIPLES

2.1 Architectural concepts

For the purpose of this International Standard, a document is an amount of structured information that can be interchanged as a unit.

This part of this Standard provides the means to represent the structures of documents in two major forms:

- in a formatted form which allows documents to be presented (for example, printed or displayed) as intended by the originator;
- in a processable form which allows further processing of documents by the recipient, such as editing and formatting as intended by the originator.

It also provides the means to represent a document in formatted processable form to satisfy both purposes.

A document contains information that relates to its content and structure.

The content of a document consists of any type of information that is intended for human perception, for example, content elements that can be presented in a two-dimensional form, such as printed on paper or displayed on a screen.

The structural information included in a document is provided in order to:

- delimit portions within a document, such as areas for the imaging of different types of content elements;
- delimit portions of a document that have a logical meaning, such as chapters, paragraphs;
- use different types of coding for the different content types;
- allow processing of the document.

The rules for defining the structure and representation of documents are collectively called the document architecture.

The document architecture comprises a structural model and a descriptive representation. The structural model describes the structural elements of a document and the relationships among these elements. The descriptive representation describes how the elements of a document and the properties of these elements are represented.

The structural model and the descriptive representation present complementary views of a document. Both are necessary in order to distinguish between the structural aspects of a document and the data structures which represent those structural aspects. Also, the descriptive representation shows how additional information not described by the structural model is represented. This information includes styles and the document profile. Styles contain information relating to the layout and presentation of a document (see 2.3.5). The document profile includes information relating to the document as a whole (see 2.3.6).

This part of this Standard does not require all parts of the document architecture to be present in any particular document.

2.2 Structural model of a document

The structural model introduces the structural elements of the document architecture.

2.2.1 Specific structures

The structural model of a document provides for two different but complementary views of the content of a specific document:

- the logical view associates content with structural elements such as chapters, appendices, headings, paragraphs, footnotes and figures;
- the layout view associates content with structural elements relating to presentation media, such as pages and areas within pages.

This is illustrated in figure 2-1.
These structural elements of a specific document are called objects. Each view associates the same document content with a separate structure which consists of a hierarchy of objects. Thus:

- the specific logical structure associates the content of a document with a hierarchy of logical objects and provides for the representation of documents in processable form;
- the specific layout structure associates the content of a document with a hierarchy of layout objects and provides for the representation of documents in formatted form.

The specific structure consists of the specific logical structure and/or the specific layout structure. The structures are independent of the types of content within a document. There are two types of relationships among objects in a structure, namely:

- structural relationships which specify the hierarchical structure of the objects;
- non–hierarchical relationships which specify other relationships, such as cross-references to figures or footnotes.

### 2.2.2 Content of a document

The structural model of a document partitions the content into structural elements called content portions.

The information within each content portion must pertain to a particular type of content and the structure of this information is defined by a content architecture. A content architecture consists of the definition of a set of content elements control functions and attributes, with their coded representation, and of the rules for the application of the attributes and control functions to the content elements.

Selection of content architecture depends on the type or types of content elements to be represented. A single document may contain content portions pertaining to different content architectures. There shall be only one content architecture per content portion.

A content architecture does not identify any logical or layout objects of a document. All structural information and all logical and layout objects are specified by the logical and layout structures of the document architecture.

The document architecture supports the incorporation of the content architectures that are specified in other parts of this Standard. The document architecture has been designed to be separate from the content architectures. This is achieved since the structural model has been designed such that the properties of the structural elements that are used to describe a document are independent of the types of content that may be associated with those structural elements. Both document architecture and one or more content architectures are needed to represent a document.

The interface between the document architecture and the content architecture(s) is defined in 4.

This interface allows the use of any of the content architectures defined in other parts of this Standard with the document architecture.
2.2.3 **Generic structures**

The generic structure of a document provides for the representation of characteristics common to, and relationships between, a number of objects within a document. In the most comprehensive case it provides for the representation of the common characteristics of a group of documents.

2.2.3.1 **Object classes**

In many documents, there may be sets of objects with common characteristics; for example:
- logical objects representing sections, consisting of a sequence of subordinate objects representing paragraphs, with the same characteristics;
- pages with the same headers and footers.

An object class is a structural element of the document that models such a group of common characteristics.

This Standard does not define particular object classes; however it provides the means by which object classes can be defined.

Any content portions associated with an object class are called **generic content portions**.

For convenience of reference, the term *component* is used to refer collectively to an object or an object class.

2.2.3.2 **Document classes**

A document class is used to represent the common characteristics of a group of documents; for example, a set of reports with common paragraphs and common layout. A document class can be used to maintain consistency of an entire document during editing and/or formatting of the document.

The generic logical structure provides for the representation of the common characteristics of logical objects of a document class and the **generic layout structure** provides for the representation of the common characteristics of layout objects of a document class.

The generic logical structure consists of all the logical object classes and associated generic content portions of a document.

The generic layout structure consists of all the layout object classes and associated generic content portions of a document.

The **generic structure** consists of the generic logical structure and/or the generic layout structure.

This Standard does not define particular document classes; however it provides the means by which document classes can be defined.

2.3 **Descriptive representation of a document**

The descriptive representation introduces the descriptive elements of the document architecture. For the purpose of interchange, a document is represented as a collection of *constituents*, each of which is a set of attributes.

Within this Standard each *attribute* is identified by a name and has a value, which either represents a characteristic of a structural element or a relationship with other constituents.

This Standard defines these constituents and attributes.

Those constituents that are counterparts to the structural elements are termed *descriptions*.

2.3.1 **Constituents of a document**

The following *types of constituent* are defined:
- document profile;
- logical object class description;
- layout object class description;
- logical object description;
- layout object description;
- content portion description;
presentation style;
- layout style.

Each constituent is characterised by its attributes; within a constituent all attribute names are unique.

2.3.2 Content portion descriptions

Each content portion within a document is characterised by a set of attributes called a content portion description.

Any content portion description associated with an object class description (see 2.3.4), for example a logo block or a standard paragraph, is called a generic content portion description.

2.3.3 Object descriptions

Each object within a structure is characterised by a set of attributes called an object description. Each attribute has a value and may represent one of the following:

a) a characteristic of the object itself;
b) a structural relationship which specifies a hierarchical relationship between the object and other objects in the same structure;
c) a non–hierarchical relationship between:
   - the object and other objects in the same structure,
   - the object and other objects in different structures included in the same document,
   - the object and object classes included in the same document.

2.3.4 Object class descriptions

Each object class within a document is characterised by a set of attributes called an object class description.

An object class description for a logical object class is called a logical object class description and an object class description for a layout object class is called a layout object class description.

In general, each attribute of an object class description specifies a rule to determine the value of a corresponding attribute of an object description for an object of the object class concerned.

Object class descriptions can be used for the following purposes:

a) to improve transmission efficiency;
b) to maintain the internal consistency of a document when it is modified;
c) to facilitate the creation of objects and documents.

Object class descriptions can be used either individually or collectively.

In either case, the object class descriptions may have generic content portion descriptions associated with them.

In the case of individual use, each object class description is used for transmission efficiency and/or to facilitate creation of objects. Each such object class description consists of a set of attributes representing the common characteristics of objects of the object class.

The set of object class descriptions corresponding to this case of individual use is termed a factor set of object class descriptions.

In the case of collective use, two situations must be considered.

In the first situation, some object class descriptions are related to each other in a particular hierarchical structure. This collection serves to facilitate creation of sets of hierarchically related objects within a specific structure, but does not fully specify all possible specific structures that may be created. Such a collection is called a partial generator set of object class descriptions.

In the second situation, all object classes are related to each other such that they fully control the generation of specific structures. This collection serves to maintain consistency of an entire document during editing or formatting of the document. During creation and modification of the document, each logical object class description specifies characteristics of the objects that may be created and how these objects may build up the possible specific logical structures of the entire document. Similarly, during document layout, each layout object class description influences the creation of the possible specific layout structures.

The set of object class descriptions corresponding to this second situation is termed a complete generator set of object class descriptions.
A generic logical structure or a generic layout structure whose representation includes a partial generator set of object class descriptions is termed a partial generic logical structure or a partial generic layout structure, respectively.

A generic logical structure or a generic layout structure whose representation includes a complete generator set of object class descriptions is termed a complete generic logical structure or a complete generic layout structure, respectively.

2.3.5 Styles

In addition to logical and layout component descriptions, a document may contain a number of layout styles and presentation styles which are distinct from the component descriptions.

A style is a set of attributes which may be referred to from component descriptions. The effect of such a reference is to apply the attributes of the style to the component description which contains the reference.

A layout style is a set of attributes referred to from one or more logical component descriptions which during document layout guides the creation of a specific layout structure. That is, a layout style provides information for the creation of pages and, if required, guides the division of pages into separate areas, for the layout of the document content.

A presentation style is a set of attributes referred to from one or more basic logical and/or layout component descriptions which guides the format and appearance of the content of the document on the presentation medium.

The separation of styles from the component descriptions allows the layout and presentation of a document to be modified without affecting the logical structure.

2.3.6 Document profile

The document profile consists of a set of attributes which specify characteristics of the document as a whole.

For instance, the document profile indicates which of the following are present in the document:

- logical object descriptions;
- layout object descriptions;
- logical object class descriptions;
- layout object class descriptions;
- presentation styles;
- layout styles.

The document profile specifies the document architecture class used in the document. It also specifies the ODA version, document application profile, content architectures, interchange format class and document profile level used in the document.

The document profile may describe the document and its history, including information for filing and retrieval and, for example, describing the fonts used in the document.

For the convenience of the recipient, the document profile may duplicate information usually found in the document content (for example, document name, author, date, etc.). However, the document profile does not include data specific to a particular mode of transmission, such as mail, message or Teletex.

A document profile may be interchanged alone to allow a sender to test the capability of the recipient, or for the recipient to get information about the document without sending the complete document.

A complete specification of the document profile is found in part 4 of this Standard.

2.3.7 Document class descriptions

A document class is specified by a document class description.

A document class description consists of one of the following:

a) a document profile,
   a complete generator set of logical object class descriptions,
   optionally layout styles,
   optionally presentation styles,
   optionally generic content portion descriptions; or
b) a document profile,
a complete generator set of layout object class descriptions,
on Optionally presentation styles,
on optionally generic content portion descriptions; or

c) a document profile,
a complete generator set of logical object class descriptions,
a complete generator set of layout object class descriptions,
on possibly layout styles,
on optionally presentation styles,
on optionally generic content portion descriptions.

A document class description defines how to generate an entire specific logical and/or specific layout structure for any document of the class.

Documents may reference one externally specified document class description (see 2.3.9). In this case, the document profile indicates whether an external-document class description is referenced by the document, and if so, which one.

2.3.8 Generic-documents
A generic-document description consists of one of the following:

a) a document profile,
a complete generator, partial generator or factor set of logical object class descriptions,
on optionally layout styles,
on optionally presentation styles,
on optionally generic content portions; or

b) a document profile,
a complete generator, partial generator or factor set of layout object class descriptions,
on optionally presentation styles,
on optionally generic content portions; or

c) a document profile,
a complete generator, partial generator or factor set of logical object class descriptions,
a complete generator, partial generator or factor set of layout object class descriptions,
on layout styles,
on optionally presentation styles,
on optionally generic content portions.

A generic-document may be interchanged and used to aid in the generation of documents. Resource-documents and external-documents are examples of generic-documents.

2.3.9 External-document class description
An interchanged document that does not contain a generic structure can refer to an external-document. The external-document is identified in the interchanged document profile. The reference is ignored if any generic layout structure or generic logical structure is present in the interchanged document. Styles may be present in both the interchanged document and the external document.

The external-document can provide any or all of:
- constituents representing a complete generic logical structure;
- constituents representing a complete generic layout structure;
and optionally:
- layout styles;
- presentation styles.

An external-document contains a document profile which supplies information for the constituents and styles in the external-document, for example, a fonts list. The information in this document profile cannot be used by the interchanged document except by reference to the constituents and styles in the external-document.

If layout or presentation styles in the interchanged document and the external-document have the same identifier then the style in the interchanged document is used and the style in the external-document is ignored.
2.3.10 Resource-documents

An object class description in a given interchanged document may contain a reference to an object class description external to the document, in a generic-document. The latter generic-document is called the resource-document of the interchanged document.

The object class descriptions contained in the resource-document act as models for object class descriptions in the interchanged document.

The attributes constituting an object class description in the resource-document may supply values for the corresponding attributes of those object class descriptions in the interchanged document that refer to this object class description in the resource-document.

A resource-document may contain generic content portion descriptions to be included by reference into an interchanged document referring to this resource-document.

Thus, the relationship between an object class description in the interchanged document and the corresponding object class description in the resource-document is similar to the relationship between an object description and the corresponding object class description in the interchanged document.

A resource-document is separate from any document or documents referring to it.

2.3.11 Classes of document architecture

A document architecture class is a set of rules for defining the structure and representation of documents in formatted form, processable form, or formatted processable form.

Section 8 defines three document architecture classes that may be used in conjunction with document application profiles, as defined in part 1 of this Standard.

The three classes of document architecture are:

a) Formatted document architecture class which allows for document content to be presented as intended by the originator; for example, printed or displayed. A document of this class includes a document profile and constituents representing a specific layout structure. It may also include constituents representing a generic layout structure and presentation styles.

b) Processable document architecture class which allows for document content to be processed; for example, edited or formatted. A document of this class includes a document profile and constituents representing a specific logical structure. It may also include constituents representing a generic logical structure, a generic layout structure, layout styles and presentation styles.

c) Formatted processable document architecture class which allows for document content to be processed as well as presented as intended by the originator. A document of this class includes a document profile, constituents representing a specific logical structure, a specific layout structure and a generic layout structure. The generic layout structure can be omitted if there is a reference to an external-document containing at least a complete generic layout structure. The document may also include constituents representing a generic logical structure, layout styles and presentation styles.

A generic-document may be assigned to one of the preceding classes, by the following rules:

a) If the generic-document contains logical object class descriptions, and no layout object class descriptions, it is assigned to the processable document architecture class;

b) If the generic-document contains layout object class descriptions, and no logical object class descriptions, it is assigned to the formatted document architecture class;

c) If the generic-document contains both logical and layout object class descriptions, it is assigned to the formatted processable document architecture class.

2.3.12 Sets of constituents

A document is represented by constituents, which are grouped into sets of constituents, and which have inter-relationships, as defined in this Standard.

The possible types of constituent in the descriptive representation of a document are shown in figure 2-2.

Figure 2-2 illustrates that:

a) the document consists of one document profile and optionally a number of constituents that form the document body;
b) the *document body* consists of one of the following sets:
   1) constituents representing the generic structure, and optionally style constituents;
   2) constituents representing the specific structure, and optionally style constituents;
   3) constituents representing the generic structure, the specific structure, and optionally style constituents;
   c) the constituents representing the generic structure consist of constituents representing the generic logical structure and/or constituents representing the generic layout structure;
   d) the style constituents of a document consist of layout styles and/or presentation styles;
   e) the constituents representing the specific structure consist of constituents representing the specific logical structure and/or constituents representing the specific layout structure;
   f) the constituents representing the generic logical structure consist of the logical object class descriptions and any associated generic content portion descriptions;
   g) the constituents representing the generic layout structure consist of the layout object class descriptions and any associated generic content portion descriptions;
Figure 2-2  – Descriptive model of a document
h) the constituents representing the specific logical structure consist of the logical object
descriptions and any associated content portion descriptions;
j) the constituents representing the specific layout structure consist of the layout object
descriptions and any associated content portion descriptions;
k) if both the specific logical structure and specific layout structure are present in a document,
then the content portions associated with these structures are, in general, common to both.

2.4 Document processing model
This clause describes a conceptual model for document processing.
It addresses only those aspects of document processing that are relevant to the document
architecture defined in this Standard. As such, it is not a complete model of document processing
since it does not specify all processing steps from document creation to document imaging.
It describes the principal operations performed on a document as a basis for understanding the
semantics of the attributes defined in 5.
It is not intended to represent an actual implementation, nor to restrict in any way the processing
that may be applied to an interchanged document.
The document processing model (see figure 2-3) is summarized in this section. Three processes are
shown:
   – the editing process;
   – the layout process;
   – the imaging process.
The order of processes in the diagram is not intended to imply that they are performed sequentially
in an actual implementation.
The document processing model provides for manual intervention only for carrying out editing
processes on the specific logical structure and content. Manual intervention can occur, however, at
many stages in the model, but it is neither explicitly allowed nor prohibited by this Standard.
For example, in an actual implementation it may be possible to create and amend the logical and
layout object class descriptions, and layout and presentation styles, but these processes are not
included in this model since this Standard does not place any constraints on such editing.

2.4.1 The editing process
The editing process includes both document creation and document revision as these activities
are indistinguishable from an architectural perspective.
This editing process includes the content editing process and the logical structure editing process.
The content editing process is concerned with the creation of new content or the modification
of previous content. The logical structure editing process is concerned with the creation of a
specific logical structure or the modification of a previous specific logical structure and the
allocation of content to basic logical objects. Modifications to the specific logical structure are
required to conform to the rules specified in the generic logical structure, if present.
Included in the document creation and document revision activities are the creation of the
generic logical structure, the generic layout structure, layout styles and presentation styles.
Styles may be altered to represent changes made during the logical structure editing process. The
generic layout structure may be edited in order to alter the intended layout of the document.

2.4.2 The layout process
The layout process includes the document layout process and the content layout process. These
processes are concerned with the creation of a specific layout structure which can be used by the
imaging process to present the document in human perceptible form on a presentation medium.
The document layout process creates a specific layout structure in accordance with the generic
layout structure and information derived from the specific logical structure, the generic logical
structure and layout styles (if present).
This process also determines the areas that are available within the created layout objects for the
formatting of the document content (as described below) and is responsible for allocating the
content to these available areas.
The content layout process is responsible for formatting (or laying out) the content portions into
the available areas specified by the document layout process. This process makes use of
information contained in the presentation attributes that apply to those content portions.
During the layout process, presentation attributes may be derived from presentation styles referenced by the logical structure, from the generic layout structure, and from presentation styles referenced by the generic logical structure. Derivation of presentation attributes from the logical structures has precedence over derivation from the generic layout structure. Those presentation attributes derived from the logical structures that differ from those derived from the generic layout structure will be specified explicitly in the specific layout structure by the layout process.

The document layout process is described in 6. The content layout process depends on the content architecture pertaining to the content being laid out and is described in those parts of this Standard that are concerned with particular content architectures.

The role of the constituents that represent the generic logical structure is different in the editing process and the layout process. In the editing process, the logical object class descriptions are used to construct the specific logical structure. In the layout process, a logical object class description is used as a source of attributes and content, if any, that is common to the logical objects of the class.
Figure 2-3  – Document processing model
2.4.3 The imaging process

The imaging process consists of taking a specific layout structure and a corresponding generic layout structure (if present), with associated formatted content portions and information contained in presentation styles, and displaying it on a suitable presentation medium.

Some aspects particular to the imaging process are described in section 7. However, the imaging process is a locally defined process. Hence, apart from defining the input information required by this process, which is the specific and generic layout structures, referenced presentation styles and the formatted content portions, this process is not formally defined in this Standard.

During the imaging process, presentation attributes are derived from the layout structures and referenced presentation styles. Any presentation attributes specified by the logical structures and referenced presentation styles are ignored.

The role of the constituents that represent the generic layout structure is different in the document layout process from that in the imaging process. In the document layout process, the layout object class descriptions are used to construct the specific layout structure. In the imaging process, a layout object class description is used as a source of attributes and content, if any, that is common to the layout objects of the class.

Some aspects of imaging depend on the content architecture pertaining to the content to be imaged and are described in those parts of this Standard that are concerned with particular content architectures.

2.5 Roles of the document architecture constituents in document processing

2.5.1 Editing process

This clause describes the role of the various parts of the document architecture when the editing process is applied to documents of processable or formatted processable class.

2.5.1.1 Generic logical structure

The generic logical structure can be used to control the editing process that can be carried out on a document. This is accomplished by providing references from logical object descriptions to logical object class descriptions.

If a complete generator set of logical object class descriptions is present in the document then there is a reference from every logical object description to a logical object class description.

A complete generator set of logical object class descriptions controls the specific logical structure which is produced during the document creation and editing process. This is achieved by ensuring that logical objects are only created, deleted or modified according to corresponding logical object classes in the generic logical structure. In addition, the creation of a new logical object is facilitated because a logical object class description serves as a template for the logical object description.

A partial generator set of logical object class descriptions is similar to a complete generator set, except that it controls only portions of the specific logical structure rather than all of it.

If a factor set of logical object class descriptions is present in the document, then the object classes in that structure can be used to facilitate the creation of objects in the specific logical structure that have common properties. This is achieved by providing references from a logical object description to a logical object class description. This provides a means of reducing the amount of common information in objects of the specific logical structure, this is referred to as "factorization" of information.

A factor set of logical object class descriptions has no control over the structure of the specific logical structure.

2.5.1.2 Specific logical structure

The logical structure editing process involves making changes in the specific logical structure. These changes may be as follows:
- creating or deleting a logical object;
- changing the position of an object in the specific logical structure;
- changing the characteristics of an object by adding, deleting or modifying attributes specified by the object description.
Changing the characteristics of an object can also involve:
- changing the layout styles referenced by the object description;
- changing, adding or deleting a default value for an attribute in a default value list for a logical object description.

2.5.1.3 Content
The content editing process involves making changes to the content. Representing this can involve making changes to the presentation styles applicable to the basic logical object descriptions.
In order to edit the content it must be in processable or formatted processable form. The content is changed by:
  a) adding, modifying or deleting one or more content elements;
  b) adding, modifying or deleting embedded control functions.
Editing of formatted form content is outside the scope of this Standard. However, all three forms of content may be specified by the content portions of the logical structure.
The editing algorithms used to change the content are not described in this model as they are outside the scope of this Standard.

2.5.1.4 Generic layout structure
The generic layout structure, if present in the document, plays no direct role in the editing process.
However, the generic layout structure may be edited in order to alter the intended layout of the document. This process is of local concern only and is outside the scope of this Standard.

2.5.1.5 Specific layout structure
The specific layout structure, if present in the document, plays no direct role in the editing process.
However, the specific layout structure which will be produced by the document layout process may be changed as a consequence of the editing process modifying the specific logical structure or the document content.

2.5.1.6 Layout styles
Layout styles are not used to represent controls on the editing process.
Layout styles may be altered to represent changes made during the logical structure editing process (see 2.5.1.2). This involves the addition, deletion or modification of the layout directive attributes contained in a layout style. This can affect the layout characteristics of all the logical objects whose representation refers to the style and can affect the relationships that the objects have with other objects in the document. The result of changing the layout styles is that it may cause changes in the specific layout structure produced by the document layout process.

2.5.1.7 Presentation styles
Presentation styles are not used to represent controls on the editing process.
Presentation styles may be altered to represent changes made during the content editing process. This involves the addition, deletion and modification of attributes contained in the presentation styles. This can affect the layout and imaging of the content associated with all the basic logical objects whose representation refers to the presentation styles that are changed. For some presentation attributes, the same effects may be produced by editing the control functions that are embedded in the content but such editing will only alter the layout and imaging of the content in which the edited control functions are embedded.

2.5.2 Layout process
This clause describes the role of the various parts of the document architecture when the layout process is applied to documents of processable or formatted processable class. A model of this process is described in section 6 of this part of this Standard.
2.5.2.1 **Generic logical structure**
During the layout process, the generic logical structure may provide layout styles, presentation styles and generic content portions which may affect the creation of the specific layout structure.
Also, object classes may be referenced by the attribute “logical source” that is contained within layout object class descriptions. This results in the creation of additional layout objects that have no correspondence with any objects in the specific logical structure.

2.5.2.2 **Specific logical structure**
During the layout process, the sequential logical order of the objects in the specific logical structure determines the sequence in which the content of the document is considered by the layout process.
In addition, the logical objects can provide layout directives which direct the document layout process and presentation attributes which direct the content layout process. These layout directives and presentation attributes are specified by referencing a layout style or a presentation style, respectively.

2.5.2.3 **Layout styles**
During the layout process, layout styles provide layout directives which direct the document layout process.

2.5.2.4 **Presentation styles**
During the layout process, presentation styles provide presentation attributes which direct the content layout process.

2.5.2.5 **Content**
During the layout process, the content is allocated to basic layout objects. The division of the content into content portions may be modified so that it is consistent with both specific structures. In addition, the content layout process may insert control functions into the content to facilitate the imaging process.

2.5.2.6 **Generic layout structure**
During the layout process, a complete generator set of layout object class descriptions must be available to determine a specific layout structure for the document.
The construction expressions specified by the layout object class descriptions determine all permissible specific layout structures which may be created by the layout process. Which of these permissible structures is used is determined from the specific logical structure, the generic logical structure, the content, and the layout and presentation styles.

2.5.2.7 **Specific layout structure**
The specific layout structure results from applying the document and content layout processes to the specific logical structure, the content, the generic logical structure, the generic layout structure, layout styles and presentation styles.

2.5.2.8 **Generic content**
Generic content portions associated with logical object classes may be in formatted, processable or formatted processable form. Whenever such a logical object class specifying a generic content portion is referred to from a basic logical object in a specific logical structure, the generic content is laid out in accordance with the document and content layout processes and a new basic layout object is created and added together with the created content portion to the specific layout structure.
Generic content portions associated with layout object classes may be in formatted or formatted processable form. The layout of such content portions during the layout process does not cause additional content portions to be added to the specific layout structure. However, the content portions are indirectly associated with the specific layout structure by reference to the appropriate layout object class description.
2.5.3 Imaging process
This clause describes the role of the various parts of the document architecture when the imaging process is applied to documents of formatted or formatted processable class.

2.5.3.1 Content
In the imaging process, the content, together with the specific layout structure, is used to produce an image of the document perceptible to a human.
After layout, the content may be either in formatted form or in formatted processable form. Both forms of content are suitable for imaging.

2.5.3.2 Generic layout structure
During the imaging process, the generic layout structure may provide, for the layout objects in the specific layout structure, any combination of the following:
- a) attributes that direct the imaging of the content;
- b) generic content portions.

2.5.3.3 Specific layout structure
In the imaging process, the specific layout structure, together with the content, is used to produce a human-perceptible image of the document.
The sequential order of the objects in the specific layout structure determines the precedence for imaging the content of the document by the imaging process. It is also possible to change the precedence of the layout objects by specifying an imaging order which is different from the sequential layout order.

2.5.3.4 Layout styles
In the imaging process, layout styles play no role.

2.5.3.5 Presentation styles
In the imaging process, the presentation attributes of the presentation styles referenced by the layout structures may affect the image generation of the content.

3. DOCUMENT STRUCTURES

3.1 Specific structures

3.1.1 General principles
The specific layout and specific logical structures of a document are hierarchical structures of objects.
The object at the highest level in the hierarchy of the specific layout structure is called the document layout root and the object at the highest level in the hierarchy of the specific logical structure is called the document logical root.

A composite object is an object that has one or more subordinate objects. The structural relationships of a composite object identify its immediate subordinates.
The minimum number of hierarchical levels below the highest level in either structure is one. Thus, the document root object is always a composite object. The actual number of levels is variable and depends upon a given document.

In general, at any level in a specific structure, the subordinates of any composite object can consist of any number and combination of basic objects and composite objects.

Basic objects are objects that have no subordinate objects.
Basic objects are also distinguished from composite objects since basic objects are the only objects with which the content of a document is directly associated (see 3.1.3). Every basic object has content, either in the form of one or more specific content portions, in the form of an expression for generating content or derived from an object class to which the basic object belongs.

Each object in a structure is of a certain object type. The object types that can occur within a specific logical structure or a specific layout structure are defined in clauses 3.2 and 3.3, respectively. The object type determines which attributes are applicable to an object description.
The particular attributes and attribute values comprising the object description characterise the object, that is, the attributes specify the characteristics of the object itself and specify the relationships that it has with other components in the document.

Each object in a structure is uniquely identified within that structure. The structural relationships between a composite object and its immediate subordinates are defined in the composite object description.

3.1.2 Sequential order

In the case that more than one immediate subordinate is identified by a composite object then the composite object description specifies an ordering of these immediately subordinate objects. This subordinate ordering is used to define a unique sequential ordering of all the objects in a structure.

This sequential order is such that each object in the structure is succeeded by all of its immediate subordinates, before any other objects with the same immediate superior. Each of the immediate subordinates is followed by all of its immediate subordinates, before proceeding to the next immediate subordinate in sequence. The immediate subordinates occur in the subordinate ordering defined within the object description.

The sequential order of the specific logical structure is called the sequential logical order; the sequential order of the specific layout structure is called the sequential layout order.

The sequential logical order defines the order that the logical objects are intended to be processed by the layout process (see 6).

The sequential layout order defines the order of precedence for imaging unless this is overridden by the specification of an imaging order in the object description (see clause 7.1).

An example of the sequential order of a structure is shown in figure 2–4, where the numbers indicate the sequential order.

![Diagram showing sequential order](image)

Note: arrows define sequential order

Figure 2–4 – Example of sequential order
3.1.3 Content portions

The content of a document is divided into content portions to allow the document architecture to address each content portion as a unit. The amount of content to be placed into a content portion may vary from no content elements to the entire document content. The maximum number of consecutive content elements that have the same properties and characteristics will typically be placed together in one content portion. For example, a content portion may represent a heading, paragraph, picture or perhaps just that amount of content that needs to have particular constraints regarding its imaging or processing.

Each content portion is structured according to a single content architecture. When a document contains only a single specific structure, either a specific layout structure or a specific logical structure, each content portion in the specific structure is associated with a single basic object. Each basic object may have more than one associated content portion, provided that all of these content portions pertain to the same content architecture. In the case that more than one content portion is associated with a basic object then the object description specifies the ordering among these content portions.

3.2 Specific logical structures

The specific logical structure provides a means of modelling the structure of a document in terms of logical objects which have meanings that are significant to the application or user.

For example, the specific logical structure can be used to model a document in terms of chapters, sections, paragraphs and footnotes. This Standard does not standardise such particular kinds of logical objects. However, it does provide the means by which any such construction can be defined in terms of logical objects to be interpreted as chapters, sections, paragraphs or footnotes etc.

The significance of this form of definition is that instead of standardising a few particular kinds of logical objects it allows any number of differing kinds of logical objects to be constructed, so as to meet a wide variety of needs.

Logical objects provide the means to specify the specific logical structure of a document that is relevant to a particular application of this Standard. For example, the specific logical structure may be required in the processing of a document, such as editing and laying out the document.

Section 5 defines the attributes that are used to describe the characteristics of logical objects, including the use of presentation styles and layout styles.

The objects that can occur within a specific logical structure of a document are of the following object types:

- document logical root;
- composite logical object;
- basic logical object.

The allowable hierarchical relationships between logical objects are shown in figure 2-5.

NOTE 2-2

The notation used in this figure is that defined in Appendix A.
3.2.1 Document logical root
The document logical root is the highest level object in the hierarchy of the specific logical structure. It is a composite object whose immediate subordinates consist of any number and combination of basic logical objects and composite logical objects.

3.2.2 Composite logical objects
A composite logical object is a composite object that is immediately subordinate either to the document logical root or to a composite logical object of a hierarchically higher level. Its immediate subordinates consist of any number and combination of composite logical objects and basic logical objects. Thus, the number of hierarchical levels between any given basic logical object and the document logical root is variable.

The use of composite objects is optional. Content portions cannot be directly associated with composite logical objects.
The hierarchical relationships between a composite logical object and its subordinates can express a logical relationship between that composite logical object and its subordinates that has a significance relevant to a particular application of this Standard. For example, these relationships may be used to specify which sections, paragraphs and diagrams relate to a certain chapter in a document.

3.2.3 Basic logical objects

A basic logical object is a basic object that is immediately subordinate either to the document logical root or to a composite logical object.

A basic logical object is a container for portions of the document content. Zero, one or more content portions are directly associated with a basic logical object. In the case that zero content portions are directly associated, the content is either specified in the form of an expression for generating content or is derived from a basic object class description.

3.3 Specific layout structure

The specific layout structure provides a means of modelling the structure of a document in terms of layout objects which have meanings that are significant for the layout process and the imaging process.

Section 5 defines the attributes that are used to describe the characteristics of layout objects, including the use of presentation styles.

3.3.1 Objects of the layout structure

The objects that can occur within the specific layout structure of a document are of the following object types:

- document layout root;
- page set;
- composite or basic page;
- frame;
- block.

The allowable hierarchical relationships between layout objects are shown in figure 2-6.

NOTE 2-3

The notation used in this figure is that defined in Appendix A.

3.3.1.1 Document layout root

The document layout root is the highest level object in the hierarchy of the specific layout structure. It is a composite object whose immediate subordinates consist of any number and combination of page sets and pages.

3.3.1.2 Page set

A page set can be used to identify a number of page sets or pages (or a combination of both) as a group, for example, the pages which contain a particular section of a document.

A page set is a composite object that is immediately subordinate to either the document layout root or to a page set of a hierarchically higher level. Its immediate subordinates consist of any number and combination of page sets and pages. Thus the number of hierarchical levels between any given page and the document layout root is variable.

3.3.1.3 Page

A page is a rectangular area used as the reference area for positioning and imaging the content of the document. Its size may be smaller than, equal to or greater than the size of the presentation medium.

A page is immediately subordinate either to the document layout root or to a page set.

A page can be a basic object or a composite object.

The pages within a layout structure can either be basic or composite pages, but not a combination of these.
If a page is a basic object, then zero, one or more content portions are directly associated with the page. In the case that zero content portions are directly associated, the content is derived from a basic object class description.

If a page is a composite object, then its immediate subordinates consist of either any number of frames or any number of blocks.

3.3.1.4 Frame

A frame is a rectangular area that is contained entirely within the area of the object to which it is immediately subordinate. It is positioned so that its sides are parallel to the sides of the enclosing page. Frames are used to define areas for laying out the content associated with composite pages.

A frame is a composite object that is immediately subordinate to a composite page or to an enclosing frame. The immediate subordinates of a frame consist of either any number of frames or any number of blocks. A lowest level frame on any branch of the layout structure is a frame which does not have any subordinate frames. Only lowest level frames can contain blocks. The number of hierarchical levels between any given block and the enclosing page is variable.

3.3.1.5 Block

A block is a rectangular area that is contained entirely within the area of the object to which it is immediately subordinate. It is positioned such that its sides are parallel to the sides of the enclosing page. A block is an area for the positioning and imaging of portions of the document content.
Figure 2-6  – Permissible specific layout structures
A block is a basic object that is immediately subordinate to a page or a frame. Zero, one or more content portions are directly associated with a block. In the case that zero content portions are directly associated, the content is derived from a basic object class description.

3.3.2 Positioning layout objects
This clause defines the rules for positioning and dimensioning frames and blocks within pages. These layout objects are used to layout and image the content of documents.

3.3.2.1 Page co-ordinate system
The positions of all layout objects subordinate to pages are specified directly or indirectly, by means of an orthogonal page co-ordinate system. The origin of the page co-ordinate system is the top left corner of the page. The horizontal axis coincides with the top edge and the vertical axis coincides with the left edge of the page. The horizontal and vertical axes determine the horizontal direction and vertical direction, respectively, of the subordinate layout objects, as shown in figure 2-7. This figure also defines names for corners of a layout object: top left corner, top right corner, bottom left corner and bottom right corner. Horizontal positions are measured positively from the vertical axis to the right and vertical positions are measured positively from the horizontal axis downward.

The origin of the page co-ordinate system is the reference point used for positioning.

![Diagram of page co-ordinate system]

Figure 2-7 – The horizontal and vertical directions of layout objects
3.3.2.2 Positioning of frames
The reference point for positioning a frame is the top left corner of that frame. Frames are positioned relative to the reference point of the object to which they are immediately subordinate. Thus, frames that are immediately subordinate to a page are positioned relative to the origin of the page co-ordinate system. Frames which are immediately subordinate to another frame are positioned relative to the reference point of that frame.

3.3.2.3 Positioning of blocks
The reference point for positioning a block is the top left corner of that block. Blocks are positioned relative to the reference point of the layout object to which they are immediately subordinate.

Thus, blocks that are immediately subordinate to a page are positioned relative to the origin of the page co-ordinate system. Blocks that are immediately subordinate to a frame are positioned relative to the reference point of that frame.

3.3.3 Naming of edges of frames and blocks
In the following definition the layout path (see 5.4.2.2, 6.5 and 6.6) referred to is that specified for a frame, or in the case of a block for its immediately superior frame.

For a frame or block, the leading and trailing edges are defined as the two opposite edges of the same frame or block that are orthogonal to the direction of layout path, such that the direction from the trailing edge to the leading edge is in the same direction as the layout path.

The left-hand and right-hand edges of a frame or block are defined as the two opposite edges of the same frame or block that are parallel to the direction of layout path, such that the direction from the right-hand edge to the left-hand edge is at an angle of 90° anti-clockwise relative to the direction of the layout path.

The names of the edges of frames and blocks are illustrated in figure 2–8.

3.3.4 Measurement

3.3.4.1 Basic measurement unit
For the purpose of conveying the originator’s intentions, all dimensions and positions are expressed in basic measurement units (BMU). The value of the basic measurement unit is equal to 1/1200 of 25.4 mm. A locally defined scaling factor may be used to map the document to a particular imaging device.

3.3.4.2 Scaled measurement units
All attributes and numeric control function parameters that specify absolute or relative positions and dimensions are expressed as integral multiples of a scaled measurement unit (SMU) that is equal to m/n basic measurement units. The unit scaling factor is specified in the form of two integers m and n by the document profile attribute “unit scaling” (see part 4 of this Standard). When the attribute “unit scaling” is not specified, the scaled measurement unit used in the positioning and dimensioning attributes is equal to the basic measurement unit.
Figure 2-8  – Naming of the edges of blocks and of their immediately superior frames
3.3.5 Borders of frames and blocks
Borders can be specified to be around the edges of blocks or within the edges of frames. A border consists of the border freespace and the border line (see figures 2–9 and 2–10). The border line is described by specifying its width and line type. Line type can take the values solid, dashed, dot, dash-dot, dash-dot-dot or invisible. The border freespace is described by specifying its width. The border may be specified for a particular set of edges of the frame or block, or for all edges. The characteristics of the border for each of the edges may have a separate specification.

3.3.5.1 Borders of blocks
A border around a block is illustrated by figure 2–9. In the case of a block, the border freespace provides a region which surrounds the block between the block boundary and the border line. The border surrounds the block and does not intrude on the block. The border is contained entirely within the area of the object to which the block is immediately subordinate. This means that the document layout process must take the border into account in determination of the available area.

3.3.5.2 Borders of frames
A border within a frame is illustrated by figure 2–10. In the case of a frame, the border freespace provides a region which is within the frame between the frame boundary and the border line. The border reduces the available area within the frame for layout purposes. This means that the document layout process must take the border into account in determination of the available area.
Figure 2-9  – Border around a block

Figure 2-10  – Border within a frame
3.4 Documents containing both specific structures

When a document contains both a specific layout structure and a specific logical structure, each content portion in the specific structure is in general associated with both of the structures. However, some of these content portions can be associated with the specific layout structure only. These are the content portions that:

- represent formatted content corresponding to generic content portions associated with a basic logical object class of the generic logical structure or resource-document;
- are created as a result of the attribute "content generator";
- are created as a result of the attribute "logical source" of a layout object class description.

The allocation of content portions to basic objects in the specific layout structure may not correspond to the allocation of content portions to basic objects in the specific logical structure. For example, a basic logical object representing a paragraph would need to contain at least two content portions in the case where the paragraph was split across a page boundary. This is shown in figure 2–11 if the middle basic logical object represents the split paragraph and the composite layout objects represent the two separate pages.

This is in contrast to the situation when a document contains only one specific structure, in which case there is no need for dividing the content associated with a basic component into more than one content portion.

Figure 2–11 also illustrates the correspondence between logical and layout objects in the case that there is both a specific logical structure and a specific layout structure.

The presentation attributes for a content portion are specified by the layout structure and referenced presentation styles, any specified by presentation styles referenced by the logical structure are ignored.

In the imaging process, the logical structure and referenced styles are ignored.
Figure 2–11  – Example of relationship between logical and layout objects and associated content portions
3.5 Generic structures

3.5.1 General principles

The generic structure of a document describes characteristics common to a number of objects within a document. In the most comprehensive case it describes the common characteristics of a document class.

The generic structure can be used to:
- improve transmission efficiency by factorisation;
- maintain the internal consistency of a document by providing the recipient with the structural information necessary to edit and/or lay out the document as intended by the originator;
- facilitate the creation of objects and documents by the recipient as prepared by the originator.

The generic structure consists of a generic logical structure and/or a generic layout structure. Within the set of constituents representing the generic structure each object class description consists of attributes which parallel the attributes of object descriptions. These attributes can be used to determine the value(s) for the attributes of the corresponding object descriptions. The object class descriptions may also contain references to layout and presentation styles. If an attribute value is specified explicitly in an object description then this overrides any value that may be derived from the corresponding attribute of an object class description.

Each object class in a generic structure specifies the object type of all the objects that are derived from the object class. There may be many object classes of the same object type. The object types that can occur are specified in 3.5.6 and 3.5.7.

Each object class in a generic structure is uniquely identified within that structure. Object classes for basic objects may specify content, either in the form of generic content portions or by specifying an expression to generate content.

3.5.2 Generator and factor sets of object class descriptions

A complete generator set of logical object class descriptions can be used to control the editing process. In a document with such a complete generator set every logical object description references a logical object class description.

In addition, the generation of immediate subordinates is completely derived from the referenced logical object class descriptions.

A partial generator set of logical object class descriptions can be used to guide the generation of sub–hierarchies of the specific logical structure during the editing process. In a partial generator set, some composite logical object class descriptions may constrain the possible subordinates for objects of the class, while others do not.

A factor set of logical object class descriptions can be used to guide the creation of logical objects during the editing process. In a factor set, the composite logical object class descriptions do not constrain the possible subordinates for objects of the class. Such a factor set need not include an object class description corresponding to the document logical root.

A complete generator set of layout object class descriptions can be used to control the layout process. In a document with such a complete generator set every reference from the layout directive attributes, either by layout reference or layout category, is satisfied in the layout object class descriptions.

If the constituents representing the specific layout structure are present together with such a complete generator set then every composite layout object description references a layout object class description; and the generation of immediate subordinates is completely derived from the referenced layout object class descriptions. A block may or may not reference a layout object class description.

A partial generator set of layout object class descriptions can be used to guide the generation of sub–hierarchies of the specific layout structure. In a partial generator set, some composite layout object class descriptions may constrain the possible subordinates for objects of the class, while others do not.
A factor set of layout object class descriptions can be used to guide the creation of layout objects. In a factor set, the composite layout object class descriptions do not constrain the possible subordinates for objects of the class. Such a factor set need not include an object class description corresponding to the document layout root.

In any of the preceding cases, object class descriptions achieve factorisation by holding information that is common to a number of object descriptions. Such factorisation of attribute values, by avoiding replication, can result in improved transmission efficiency and can also facilitate the creation of objects by the recipient. Such factorisation applies to content when an object class description either specifies generic content portion description(s) or specifies an expression to generate content.

3.5.3 Complete generator sets of object class descriptions

A complete generator set of layout object class descriptions form the nodes of a single directed graph.

A complete generator set of logical object class descriptions form the nodes of a set of directed graphs. This set consists of a primary graph and, optionally, one or more secondary graphs each corresponding to the logical object class descriptions referenced by the attribute "logical source" (see 5.4.2.3).

Each directed arc of each graph connects the node from which it starts with each of the nodes which represent a possible class of immediately subordinate objects that can be generated. For any node, each possible class of immediately subordinate objects is represented by a directed arc starting from the node and ending on a node representing the class of the immediately subordinate objects.

The rules describing the possible hierarchical relationships between a composite object and its immediate subordinates, which correspond to these arcs, are defined in the object class description of the composite object.

Each graph is connected such that there is a single root node which is such that:

- it is possible to reach every other node on a path through the graph following the directed arcs;
- there is no path through the graph following the directed arcs from which it is possible to reach this single root node.

The single root node of the graph represents the object class description of object type document layout root in the set of constituents representing the generic layout structure.

The single root node of the primary graph represents the object class description of object type document logical root in the set of constituents representing the generic logical structure.

The single root node of each secondary graph represents an object class description which is identified by the attribute "logical source" of one or more layout object class descriptions.

Some paths may pass through a particular node a multiple number of times. Some of the directed arcs may start and end on the same node.

The non-terminal nodes, that is the nodes from which some directed arc starts, which in all cases include the document root itself, represent object classes for composite objects.

In the case of the terminal nodes, that is the nodes from which no directed arc starts, the situation depends on which generic structure is represented by the complete generator set of object class descriptions.

If the generic logical structure is represented, then the terminal nodes represent the object classes for basic logical objects.

If the generic layout structure is represented, then the terminal nodes represent object classes for basic pages, for blocks or for frames which will always be the lowest level frame in the particular branch of the hierarchy (see 3.5.7).

Generic content portions are only referenced from object classes for basic objects and each generic content portion must be referenced by just one object class.

3.5.4 Generation of structures

A complete generator set of object class descriptions and associated generic content portions representing a generic structure is used to maintain the internal consistency of a document. This is achieved by defining which specific structures are possible in a given document class and which object classes are possible in parts of a document (see 5.3.2.1). When creating, editing or laying
out a document, a generic structure can be used to control the generation and modification of the specific structure and thereby preserve the intentions of the originator, in this case the creator of the document class description.

Generation and modification of the specific structure is controlled by ensuring that the attributes of each object class description are used to specify default values for attributes in the corresponding object descriptions.

Recursion is permitted in the generic logical structure and in the generic layout structure, thus objects of the same object class may be hierarchically related.

This Standard does not define any particular generic structures or object classes. However, it allows the definition of a potentially infinite variety of document classes.

3.5.5 Content in generic structures
An object class description for a basic object can specify content in one of three ways:
- by specification of one or more generic content portions;
- by specification of a content generator;
- by referencing an object class in a resource-document which has content specified.

A content generator allows the content information to be specified by an expression which is evaluated during the layout process. Together with specification of a content generator a content portion description may also be present, in order to allow for specification of attributes of the content portion.

When an object class description specifies content, content portion descriptions can be derived for the specific structure.

A basic object class description with a generic content portion description may be referred to by more than one basic object description of the same specific structure and of the same object class, which permits content sharing.

3.5.6 Generic logical structure
The object classes that can occur within the generic logical structure of a document are for objects of the following object types:
- document logical root;
- composite logical object;
- basic logical object.

The possible hierarchical relationships between logical object classes are as follows:
- the object class for the document logical root can specify that there shall be any number and combination of immediately subordinate composite logical objects and basic logical objects;
- an object class for a composite logical object can specify that there shall be any number and combination of immediately subordinate composite logical objects and basic logical objects;
- an object class for a basic logical object can optionally have content specified; if content is specified then it may be in the form of one or more generic content portions, a reference to an object class in a resource-document which has content specified, or a content generator.

Object classes of these object types serve as templates for the corresponding objects in the specific logical structure.

3.5.7 Generic layout structure
The object classes that can occur within the generic layout structure of a document are for objects of the following object types:
- document layout root;
- page set;
- composite or basic page;
- frame;
- block.

The possible hierarchical relationships between layout object classes are as follows:
- the object class for the document layout root can specify that there shall be any number and combination of immediately subordinate pages or page sets;
an object class for a page set can specify that there shall be any number and combination
of immediately subordinate pages or page sets;
an object class for a composite page can specify that there shall be either any number of
immediately subordinate frames or any number of immediately subordinate blocks;
an object class for a frame can specify that there shall be either any number of immediately
subordinate frames or any number of immediately subordinate blocks;
an object class for a basic page or a block always has content specified; this may be by
specifying one or more generic content portions, by specifying a content generator, or by
referencing an object class in a resource document which has content specified.
Object classes of these object types serve as templates for the corresponding objects in the
specific layout structure. Basic objects created by the layout process, for the content associated
with the logical structures, do not reference layout object classes.

3.5.8 Resource-document
A logical object class description may contain a reference to a logical object class description in
the resource-document (see 2.3.10). A layout object class description may contain a reference
to a layout object class description in the resource-document. In both cases, a subset or all of
the attributes may be present in the object class description of the interchanged document only
implicitly, by reference to the object class description of the resource-document. This may
include the attribute "content portions", in which case content portions may be present in the
interchanged document only implicitly, by reference to the content portion descriptions of the
resource-document.
The association between the interchanged document and the resource-document is achieved
through the use of resource names. The resource-document includes, within the document
profile, a table which maps resource names onto the object class identifiers of that
resource-document. An object class description within the interchanged document may then
refer to an object class description within the resource-document by using one of these resource
names.
Attributes in the resource-document that are used by reference as attributes of object class
descriptions in the interchanged document shall not make use of object class identifiers.

4. INTERFACE BETWEEN THE DOCUMENT ARCHITECTURE AND CONTENT
ARCHITECTURES

4.1 General concept
A document is defined by means:
- of the document architecture: a finite set of constituents together with their characteristics and
  rules that establish their relationships;
- of content architectures: a finite set of content elements, (for example, graphic characters,
pdfs), together with their characteristics and rules that establish their relationships.
Content elements and control functions make up content portions governed by a content
architecture. Every content portion is associated with a basic component governed by the document
architecture.
One content element is thus specified within the document through a specific content architecture
together with the document architecture.
The terms basic values and non-basic values are used in this section:
- basic values of attributes, control function parameters and other capabilities are those that are
  unconditionally allowed in document interchange in the context of a particular document
  application profile;
- non-basic values of attributes, control function parameters and other capabilities are only
  allowed in document interchange in the context of a particular document application profile, if
  their use is declared in the document profile.
The document architecture and any content architectures are connected through an interface, as
shown in figure 2-12.
The interface is specified by describing which attributes defined in a content architecture have
influence on constituents of the document architecture (document profile, basic component
descriptions, content portions).
4.2 Specification of a content architecture

The specification of a content architecture consists of three categories of information:

- structure information that identifies the class of content architecture, its internal structure rules and the positioning and imaging rules;
- content information that determines what information comprises the content portion. It includes a set of content element repertoires along with a default repertoire and the set of control functions available in the content architecture;
- information that specifies the basic values, default values and non-basic values of presentation attributes, coding attributes and control function parameters.

This information is required in order to link the document architecture to content architecture(s), through the interface information.

![Diagram of Document Architecture and Content Architecture Interface]

Figure 2-12 – Document architecture – content architecture interface
4.3 Interface information

A content architecture has the following three interfaces to the document architecture:

- the document profile, which includes attributes that identify the content architecture class(es) used within the document and attributes that specify the use of any non-basic content architecture features;
- an object description or an object class description for a basic object, which include attributes that identify the content architecture class and presentation attributes;
- a content portion description, which includes attributes that identify the type of coding and coding attributes.

The definition of each content architecture specifies the information associated with these attributes as described in the following sub-clauses.

4.3.1 Interface between a content architecture and the document profile

The definition of a content architecture shall include the following information:

- the value(s) of the attribute used to identify the content architecture class in the document profile;
- the format of the attribute used to specify non-basic values of presentation attributes in the document profile;
- the format of the attribute used to specify default values of presentation attributes in the document profile;
- the format of the attribute used to specify non-basic values of coding attributes in the document profile;
- the format of the attribute used to specify default values of coding attributes in the document profile.

The distinction between basic and non-basic values of presentation attributes and coding attributes is not specified as a part of the definition of a content architecture. This distinction is made in the definition of a document application profile in accordance with part 1 of this Standard.

4.3.2 Interface between a content architecture and a basic component description

A definition of a content architecture shall include the following information:

- the value(s) of the attribute used to identify the content architecture class in a basic component description;
- the formats, permissible values and recommended default values of the presentation attributes;
- the presentation attributes for which a document application profile may define non-standard default values;
- possible interactions between presentation attributes and document architecture attributes.

4.3.3 Interface between a content architecture and a content portion

The definition of a content architecture shall include the following information:

- the value(s) of the attribute used to identify the type of coding in a content portion;
- the formats, permissible values and recommended default values of the coding attributes;
- the coding attributes for which a document application profile may define non-standard default values;
- possible interactions between control functions and presentation attributes.

5. ATTRIBUTE DEFINITIONS

5.1 General principles of attributes

Characteristics of structural elements of a document and relationships between structural elements are represented by constituents which are sets of attributes. Each attribute is identified by a name and has a value that describes the characteristic or relationship. Attributes are also used to identify constituents.
This section contains definitions of all attributes defined in the document architecture. The attribute definitions specify the range of values that each attribute can assume.

5.1.1 **Attribute categorisation**

Attributes are categorised according to the constituent to which they apply, as follows:
- document profile attributes;
- component description attributes;
- layout style attributes;
- presentation style attributes;
- content portion description attributes.

The constituents termed descriptions are those which are counterparts of the structural elements (objects, object classes and content portions).

Document profile attributes are defined in part 4 of this Standard. The general principles of other attribute categories are described in this clause and the attributes are defined in clauses 5.3 – 5.9.

**NOTE 2–4**
The tables in appendix F summarise all attributes defined in this section, in accordance with their categorisation.

5.1.1.1 **Attributes of components**

Attributes of component descriptions are further categorised as follows:
- shared attributes, these can be included in both logical and layout component descriptions (see 5.3);
- layout attributes, these can be included in layout component descriptions only (see 5.4);
- logical attributes, these can be included in logical component descriptions only (see 5.5);

Some attributes of components can be included in composite component descriptions only, some in basic component descriptions only and some only in component descriptions of a particular object type.

In addition, some attributes may be included in object class descriptions only, some in object descriptions only and some in both object class descriptions and in object descriptions.

All attributes, except the presentation attributes (see 5.1.1.4), are independent of the content architecture pertaining to any component descriptions.

5.1.2 **Layout style attributes**

A layout style consists of:
- a layout style identifier;
- a user–visible name;
- user–readable comments; and,
- a set of layout directive attributes.

Layout styles are referred to from logical component descriptions. Such a reference is made using the attribute “layout style” with a value equal to the value of the layout style identifier. The layout style identifier uniquely identifies the layout style within the document.

Layout styles are defined in 5.6.

A layout style may be referenced by more than one logical component description. The effect of a reference to a layout style is to apply its layout directives to that logical component description which contains the reference. Precedence rules are specified in 5.1.2.4 and 5.7.12.

The layout directives are a set of attributes which specify information for the document layout process (see 6). The layout directives guide the document layout process in generating the specific layout structure.

Layout directive attributes are defined in 5.7.

Thus, layout styles affect the layout of objects, not their content and are independent of particular content architectures. Presentation styles affect the layout and imaging of the content associated with basic objects and hence are content architecture specific. Therefore, there is no conflict between the two.
5.1.1.3 **Presentation style attributes**

A presentation style consists of:
- a presentation style identifier;
- a user visible name;
- user-readable comments;
- transparency;
- colour;
- border; and,
- sets of presentation attributes.

A presentation style may be referred to from a basic logical or basic layout component description. Such a reference is made using the attribute "presentation style" with a value equal to the value of the presentation style identifier. The presentation style identifier uniquely identifies the presentation style within the document.

A presentation style may be referenced by more than one component description.

Presentation styles are defined in clause 5.8.

The effect of a reference to a presentation style is to apply its presentation attributes, transparency, colour and border to the basic component which contains the reference. In addition, presentation attributes can be specified for basic layout components. Precedence rules are specified in 5.1.2.4.

Each set of presentation attributes corresponds to a particular content architecture class. Presentation styles affect the layout and imaging of the content associated with basic objects and hence are content architecture specific. Layout styles affect the layout of objects, not their content. Therefore, there is no conflict between the two.

5.1.1.4 **Presentation attributes**

Presentation attributes, which can be applied to basic components only, are used to specify the properties of the content portion(s) associated with that component. The presentation attributes specify information for the content layout process and content imaging process.

The presentation attributes specify the initial conditions concerned with the presentation of the content portion(s). The presentation attributes are specified either in a presentation style or, for layout components, in a basic layout component description.

The set of presentation attributes that is applicable depends upon the particular content architecture class specified for the basic component. The content architecture class attributes specify the content architecture class of the associated content portion(s), and therefore which set of presentation attributes are applicable to the content (see 5.3.4).

The presentation attributes are defined in those parts of this Standard that are concerned with individual content architectures.

5.1.1.5 **Content portion description attributes**

A content portion description consists of:
- content identifier—logical;
- content identifier—layout;
- type of coding;
- alternative representation;
- coding attributes; and,
- content information.

These attributes uniquely identify the content portion description, specify the type of coding used to code the content information and specify an alternative representation that may be imaged in lieu of content information when a recipient is not capable of decoding and/or imaging the content portion.

Content portion identifiers and alternative representation are fully specified in 5.9. Other attributes of content portions depend on the content architecture and details are specified in those parts of this Standard that deal with individual content architectures.

Content portion descriptions are defined in 5.8.
5.1.2 Attribute values

5.1.2.1 General principles

Each constituent consists of a set of attributes, the attributes in the set are said to be specified for the particular constituent.

In the case of object descriptions, the complete set of attributes describing the characteristics of the object need not be specified for the constituent, such attributes can also be derived from attributes specified for other constituents, by using defaulting rules specified in 5.1.2.4. In such cases, the attributes which are specified for the constituent, together with those derived for the constituent, are said to form the set of attributes which apply to the constituent (or that are applied to, or are applicable to, the constituent).

Attributes may be structured into parameters and sub-parameters, each attribute definition includes a specification of any such structuring.

The definition of an attribute also indicates whether the value(s) of that attribute may consist of one or more elements of data or expression(s).

Attribute values in the document profile, presentation styles and content portion descriptions can only consist of data elements of defined types; attribute values in component descriptions and layout styles may consist of either data elements or expressions.

If the value of an attribute consists of one or more data elements, then each element will be of a certain type and will be taken from a predefined set of values.

Such a value may consist of:

a) A sequence of numeric values;
b) A string of characters from a defined character set;
c) An element from a set of data elements defined for that attribute;
d) A reference to another constituent that exists within the document;
e) A reference to a value of an attribute of a constituent that exists in the document.

An example of an attribute value of type e) is the sub-parameter “fill order” of the attribute “position” (see 5.4.1.1) which can have a value equal to a member of the set {‘normal order’, ‘reverse order’}. An example of an attribute value of type d) is the attribute “presentation style”. An example of an attribute value of type e) is the parameter “binding name” of the attribute “bindings”.

Alternatively, if the value of an attribute consists of an expression, then the expression will need to be evaluated in order for the value to be interpreted. This value may depend upon the values of attributes in other constituents (see 5.1.3).

5.1.2.2 Attribute classification

Attributes can be classified as mandatory, defaultable or non–mandatory.

The classifiers are m, d, nm, as follows:

- m – Mandatory attribute: The attribute must be specified for the constituent.
- d – Defaultable attribute: The attribute need not be specified for the constituent; the value can be derived using the defaulting mechanism specified in 5.1.2.4.
- nm – Non–mandatory attribute: The attribute need not be specified for the constituent. If the attribute is not specified for a constituent, the attribute does not apply to that constituent.

Attributes of object descriptions, content portion descriptions and styles when applied to object descriptions, can be classified as either mandatory, defaultable or non–mandatory; attributes of all other constituents can only be classified as mandatory or non–mandatory.

In the case of defaultable attributes, the attribute definition also specifies the standard default value (see 5.1.2.4, 5.1.2.5).

A document application profile may specify non–standard default values for attributes (see part 4 of this Standard) If this is the case they are declared in the document profile by means of the document profile attribute “document application profile defaults”.

5.1.2.3 Default value lists

Certain attributes that are classified as defaultable may be specified in a default value list. Default value lists can be specified for composite component descriptions.
The purpose of a default value list is to allow the values of some attributes, which describe characteristics of objects in the specific layout and specific logical structures, to be specified in constituents that correspond to objects at higher levels of the hierarchical structure. The use of a default value list forms part of the defaulting mechanism defined in 5.1.2.4.

A composite component description can specify one or more default value lists. If more than one list is specified, each list applies to a different subordinate object type. Each default value list applies to all subordinate objects of the relevant object type.

For example, a default value list specified for a page can apply to subordinate frames or to subordinate blocks within the page.

5.1.2.4 Determining values for defaultable attributes of objects
The values of defaultable attributes of objects can be derived from:
1) within the object description;
2) within the object class description;
3) within a style;
4) within a default value list at higher levels of the hierarchical structure;
5) within an object class description in a referenced resource–document;
6) within a list of default values in the document profile, representing default values specified by a document application profile;
7) within this Standard.

In case 4) the attributes are interpreted as default values for the lower levels. They can be overridden by attributes of object descriptions, styles or object class descriptions specified at the lower levels.

For example, it is possible to specify:
- at document layout root level, the default page size;
- at page level, the default line spacing for blocks containing character content.

The default values for attributes applicable to logical object descriptions are determined in the sets of constituents representing the specific and generic logical structures and referenced presentation and layout styles.

The default values for attributes applicable to layout object descriptions are determined in the sets of constituents representing the specific and generic layout structures and referenced presentation styles.

To determine the value of an attribute of an object that is classified as defaultable, the value is determined by the first of the following rules which is applicable.

When an attribute is structured into two or more parameters then it can be specified that the defaulting rules are to apply to each parameter independently. When this is possible it is explicitly specified in the attribute definition, in the part of the definition which specifies the default values.

a) If an attribute value is specified for the object description concerned, then that value is used.
b) If the object description concerned refers to a style, and that style contains a value for the attribute, then that value is used.
c) If the object description concerned refers to an object class description, and that object class description contains a value for the corresponding attribute, then the value of the attribute is derived from that corresponding attribute.
d) If the object description concerned refers to an object class description, which contains a reference to a style which in turn contains a value for the attribute, then that value is used.
e) If the object description concerned refers to an object class description which refers to an object class description in the resource–document, and the object class description in the resource–document contains a value for the corresponding attribute, then the value of the attribute is derived from that corresponding attribute.
f) If the object description concerned refers to an object class description which refers to an object class description in the resource–document which contains a reference to a style which in turn contains a value for the attribute, then that value is used.
g) If a default value list specified at a higher level of the hierarchical structure is applicable to the object (that is, it is specified for this object type), and that default value list contains a value for the attribute, then the value of the attribute is derived from the value specified in that default value list.

If more than one such default value list specifies a value for the same attribute, then the value derived from the lowest hierarchical level in the structure is used.

At each level, if a default value list exists for both an object description and an object class description, then only default values which are not specified in the default value list of the object description are taken from the default value list of the object class description.

At each level, if the default value list exists for an object class description in the resource-document that is referred to by an object class description that is referred to by an object description, then only default values which are not specified in the object description or in the object class description in the interchanged document are taken from the object class description in the resource-document.

At each level the default value list may specify an attribute value directly, or indirectly via a style. In the case that an attribute value is specified in both ways in a single default value list, the value specified explicitly in the default value list is used.

h) If no value is determined by the preceding steps a) – g), and a default value is defined for this attribute by the document profile attribute “document application profile defaults” (see part 4 of this Standard) then that value is used.

j) If no value is determined by the preceding steps a) – h), then the default value defined in this Standard is used.

5.1.2.5 Determining values of attributes of content portions

The content associated to a basic object in a specific structure is determined by the first of the following to specify either any content portions or a content generator:
- the basic object description;
- an object class description referenced from the basic object description;
- an object class description in the resource-document referenced from an object class description referenced from the basic object description.

To determine the value of an attribute of a content portion that is classified as defaultable, the value is determined by the first of the following rules which is applicable.

a) If an attribute value is specified for the content portion description concerned, then that value is used;

b) If no value is determined by step a), and a default value is defined for this attribute by the document profile attribute “document application profile defaults” (see part 4 of this Standard) then that value is used;

c) If no value is determined by the preceding steps a), b), then the default value defined in this Standard is used.

5.1.3 Expressions

The value of some attributes can be specified by an expression. These attributes are:
- "generator for subordinates";
- "content generator";
- "bindings", for the parameter "binding value";
- "same layout object", for the first parameter;
- "synchronisation".

The expression permitted in the attribute “generator for subordinates” is defined in 5.3.2.1. The other possible expressions are defined in this sub-clause.

There are three types of expressions:

a) string expressions (see 5.1.3.1);

b) numeric expressions (see 5.1.3.2);

c) object identifier expressions (see 5.1.3.3).

A string expression or a numeric expression may refer to a binding value (see 5.1.3.4).
5.1.3.1 String expressions
A string expression within an attribute value specification consists of either an atomic string expression or a sequence of two or more atomic string expressions.

An atomic string expression is one of the following:
  a) a string literal;
  b) a reference to a binding value (see 5.1.3.4);
  c) a string function application (see below).

A string literal is an arbitrary octet string.

NOTE 2–5
This octet string may be interpreted in various ways, depending on the application. For example, as a character string of a particular character repertoire, as a facsimile image or as a geometric picture.

A string function application is an application of one of the functions:
  - MAKE-STRING : this function produces a character string consisting of the decimal numeral representing the numeric value of the parameter, which may be any integer (negative, zero or positive integers are permitted);
  - UPPER-ALPHA : this function produces a character string consisting of one of the upper case letters A to Z, corresponding to the numeric value (1 to 26) of the parameter;
  - LOWER-ALPHA : this function produces a character string consisting of one of the lower case letters a to z, corresponding to the numeric value (1 to 26) of the parameter;
  - UPPER-ROMAN : this function produces a character string consisting of the Roman numeral representing the numeric value of the parameter, which may be any positive integer, using the upper case letters: C,D,I,L,M,V and X;
  - LOWER-ROMAN : this function produces a character string consisting of the Roman numeral representing the numeric value of the parameter, which may be any positive integer, using the lower case letters: c,d,i,l,m,v and x.

Each of these functions has a parameter consisting of a numeric expression (see 5.1.3.2).
A string function application produces an empty string when the value of the parameter is out of range.

When two or more atomic string expressions occur in sequence each expression is evaluated independently and their results are concatenated.

5.1.3.2 Numeric expressions
A numeric expression within an attribute value specification consists of one of the following:
  a) a numeric literal;
  b) a reference to a binding value (see 5.1.3.4);
  c) a numeric function application (see below).

A numeric literal is any integer (i.e. negative, zero or positive integers are permitted).

A numeric function application is an application of one of the functions:
  - INCREMENT – this function has one parameter, consisting of a numeric expression. The result of the function is a numeric value which is one greater than the value of the parameter;
  - DECREMENT – this function has one parameter, consisting of a numeric expression. The result of the function is a numeric value which is one less than the value of the parameter;
  - ORDINAL – this function has one parameter, consisting of a reference to an object, represented by either an object identifier or an object identifier expression. The result of the function is equal to the sequence number of the specified object, within the set of objects that are immediately subordinate to the immediate superior of the specified object and belong to the same object class as the specified object. Within the set of objects that satisfy this criterion, the objects are ordered according to the sequential order and are numbered using the positive integers 1, 2, 3 etc.

The numeric value range for numeric expressions is the set of all integers (i.e. negative, zero and positive integers are permitted).
5.1.3.3 Object identifier expressions

Some attributes that apply to object descriptions have values that contain references to other object descriptions.

In an object class description or a layout style, the value of such an attribute can be represented by an object identifier expression. This is an expression that, when it is evaluated in the proper context, produces the value of an object identifier.

An object identifier expression consists of a reference to an object selection function and the specification of one or two parameters as required by the object selection function concerned.

Object selection functions are:

- CURRENT-OBJECT: a function without a parameter, which produces the identifier of the object description to which the attribute applies whose value is represented by the object identifier expression.
- CURRENT-INSTANCE: a function with two parameters, which produces the identifier of that instance of an object of the object class or object type specified by the first parameter that is current relative to the position in the specific structure of the object specified by the second parameter. (This function is explained further in 5.1.3.5).
- SUPERIOR-OBJECT: a function with a parameter, which produces the identifier of the object description that is immediately superior to the object description identified by the parameter. The parameter consists of an object identifier expression.
- PRECEDING-OBJECT: a function with a parameter, which produces the identifier of the object description that immediately precedes the object description specified by the parameter in the sequential order, (see 3.1.2). The parameter consists of an object identifier expression.

Any object selection function will produce a null object identifier when an attempt is made to reference a non-existent object. (For example, the object superior to the document layout root or the document logical root.)

5.1.3.4 References to binding values

Within string and numeric expressions it is possible to refer to the value of a binding within the attribute “bindings” of either the object description to which the attribute having the expression applies or any other specified object description. Such a reference is represented by the combination of a reference to an object description and a binding name (see 5.3.5.3). The reference to the object description is represented by an expression which when evaluated produces an object identifier.

Such an expression is called a binding reference expression. Its format is the same as that of an object identifier expression, defined in 5.1.3.3, but its semantics are as described below.

A binding reference expression consists of either an object identifier or one of the following four functions which, in this context, are called binding selection functions:

- CURRENT-OBJECT;
- CURRENT-INSTANCE;
- SUPERIOR;
- PRECEDING.

The parameters of binding selection functions as defined in 5.1.3.3, in particular object identifier expressions used as parameters have the semantics described there and are not in turn interpreted as binding selection function applications.

The semantics of the binding selection functions CURRENT-OBJECT and CURRENT-INSTANCE are identical to those of the corresponding object selection functions defined in 5.1.3.3 and 5.1.3.5.

The semantics of the binding selection functions SUPERIOR and PRECEDING are similar to those of the object selection functions SUPERIOR-OBJECT and PRECEDING-OBJECT defined in 5.1.3.3.
The differences are that, if the result of the function is the identifier of an object description that does not have an attribute "bindings" including a binding with the specified binding name, then the invocation of the function is repeated, using the identifier of the failing object description as the function parameter, until an object description is found that has an attribute "bindings" including a binding with the specified binding name.

In the case that the binding selection function is SUPERIOR, the invocation of the function is repeated on increasingly superior object descriptions, starting from the object description immediately superior to the object description specified by the parameter, until either a binding of the specified binding name is located or the document logical root or document layout root is reached.

In the case that the binding selection function is PRECEDING, the invocation of the function is repeated through the object descriptions in the reverse of the sequential order of the objects in the structure, starting from the object description immediately preceding the object description specified by the parameter, until either a binding of the specified binding name is located or the document logical root or document layout root is reached.

If the specified object identifier or the result of the binding reference expression does not pertain to an object that has a binding with the specified binding name, then the result of the reference to the binding value is either an empty string, the integer zero, or a null object identifier, depending on whether a string, a numeric value or an object identifier expression is expected in the context concerned.

The value of the binding which is referenced can contain an expression, which may itself refer to further expressions.

5.1.3.5 Current instance function

The CURRENT-INSTANCE function can be used in object identifier expressions (see 5.1.3.3) and in binding reference expressions (see 5.1.3.4). It has two parameters. The first parameter is either an object class identifier or an object type.

The second parameter consists of a reference to a logical object or layout object and is represented by either an object identifier or an object identifier expression.

The result of the function is the object identifier of that instance of the object class or object type specified by the first parameter, that is current relative to the position in the document corresponding to the logical or layout object specified by the second parameter.

To determine the result of the function, four cases are distinguished:

a) the first parameter specifies a logical object class or logical object type, and the second parameter refers to an object that is part of the specific logical structure (that is, excluding any logical objects generated as a result of the attribute "logical source");

b) the first parameter specifies a layout object class or layout object type, and the second parameter specifies a logical object that either has or has not been generated as a result of the attribute "logical source";

c) the first parameter specifies a logical object class or logical object type, and the second parameter specifies a temporary logical object that has been generated as a result of the attribute "logical source";

d) the first parameter specifies a logical object class or logical object type, and the second parameter refers to a layout object that is of a class that is referenced by at least one basic layout object without generic content.

In case a), the logical object specified by the second parameter is called the "reference logical object" and:

- if the reference logical object belongs to the object class or object type specified by the first parameter, then the result of the function is the identifier of that logical object;
- otherwise, the result of the function is the identifier of the nearest superior of the reference logical object that belongs to the object class or object type specified by the first parameter.

In case b), the "reference layout object" is defined as the first basic layout object in which any content is laid out of the logical object specified by the second parameter and:

- if the reference layout object belongs to the object class or object type specified by the first parameter, then the result of the function is the identifier of that layout object;
otherwise, the result of the function is the identifier of the nearest superior of the
reference layout object that belongs to the object class or object type specified by the
first parameter.

In case c), the "reference layout object" is defined as the first basic layout object in which
any content is laid out of the logical object specified by the second parameter and:
- the "reference logical object" is defined as the first basic object of the specific logical
structure (that is, excluding any temporary logical objects generated as a result of the
attribute "logical source") of which any content is laid out in a layout object that follows
the reference layout object in the sequential order;
- if the reference logical object belongs to the object class or object type specified by the
first parameter, then the result of the function is the identifier of that logical object;
- otherwise, the result of the function is the identifier of the nearest superior of the
reference logical object that belongs to the object class or object type specified by the
first parameter.

In case d), the "reference logical object" is defined as the first logical object of which any
content is laid out in the layout object referenced by the second parameter and:
- if the reference logical object belongs to the object class or object type specified by the
first parameter, then the result of the function is the identifier of that logical object;
- otherwise, the result of the function is the identifier of the nearest superior of the
reference logical object that belongs to the object class or object type specified by the
first parameter.

Any current instance function will produce a null identifier when an attempt is made to
reference a non-existent object. (For example, in case a) if neither the reference logical
object nor any of its superiors are of the object class or object type specified by the first
parameter.)

5.2 Attribute specification format

The attribute definitions in this section are structured as follows:

Constituents:
States the types of constituents for which the attribute can be specified. For layout directives, also
states the types of logical components to which the attribute can be applied.

Classification:
States whether the attribute is classified as mandatory, non-mandatory or defaultable, and for
which types of constituent.

Structure:
States the structuring of the attribute into parameters and sub-parameters, if any. This entry is
omitted if not applicable.

Permissible values:
States the permissible values of the attribute. If the attribute is structured into parameters and
sub-parameters the permissible values are specified for these.

Representation:
States the representation of the values in the interchange format. Only stated in certain cases, in
general this information is defined in part 5 of this Standard.

Default values:
States the default values of the attribute (see 5.1.2.4 j)). If the attribute is structured into
parameters and sub-parameters the default values are specified for these. This entry is omitted if
not applicable.

Definition:
Textual description of the semantics of the attribute.

Exceptions:
States any exceptional cases that do not follow the general rules specified for the attribute
definition. The rationale for these exceptional cases is issues such as particular optimisations
available with restricted usage of the attribute and backwards compatibility with previous standards.
5.3 Shared Attributes

The attributes defined in this clause can be specified for more than one type of constituent. Attributes that may be specified only for logical components, or only for layout components, or only for one type of constituent, are described in subsequent clauses.

5.3.1 Identification attributes

These attributes are used to uniquely identify the component to which they apply.

5.3.1.1 Object type

Constituents:
Component descriptions.

Classification:
Mandatory for all object class descriptions;
Defaultable for an object description which refers to an object class description, otherwise mandatory.

Permissible values:
A set of data elements defined for the attribute.
In the case of a layout component description: ‘document layout root’; ‘page set’; ‘composite or basic page’; ‘frame’; ‘block’.
In the case of a logical component description: ‘document logical root’; ‘composite logical object’; ‘basic logical object’.

Default value:
Never applies, since value is always determined by one of the steps a) or c) in 5.1.2.4.

Definition:
This attribute specifies the object type. The object type determines the attributes that may be specified for the object description or object class description.
In the case of a layout object description, the attribute specifies whether the object is of object type:
- document layout root;
- page set;
- composite or basic page;
- frame;
- block.
A page is a composite page if it has any subordinates (see 5.3.3.2). It is a basic page if it has no subordinates.
In the case of a logical object description, the attribute specifies whether the object is of object type:
- document logical root;
- composite logical object;
- basic logical object.
In the case of an object class description, the attribute specifies the object type of the objects in the object class.

5.3.1.2 Object identifier

Constituents:
Object descriptions.

Classification:
Mandatory, unless the exceptional case described below applies, in which case the attribute is non–mandatory.

Permissible values:
A sequence of non-negative integers. The values assigned to the first integer are:
- 1 if the constituent is a layout object description;
- 3 if the constituent is a logical object description.
Representation:
A character string consisting of decimal numerals and space characters. The decimal numerals are in one to one correspondence with the integers constituting the identifier: a space character is used as a separator between successive numerals.

Definition:
This attribute identifies an object description uniquely within the context of the document. An object identifier consists of a sequence of integers. Each integer in this sequence corresponds to a hierarchical level of the specific layout structure or specific logical structure and identifies one particular object description representing an object at that level.
The integers in this sequence start with the integer corresponding to the object description of the document layout root or document logical root. This is followed by each of the integers corresponding to the object descriptions on the path through the hierarchical structure from the document layout root or document logical root to the object description.
The first integer in the sequence indicates whether the identifier pertains to a layout object description or a logical object description.
An object identifier consisting of just a single integer identifies the object description of the document layout root or document logical root.
The actual value of each subsequent integer is not significant; however the sequence of integers allocated to each object description shall be chosen so that each object description can be uniquely distinguished from all other object descriptions in the document.

Exceptions:
This attribute is non–mandatory in certain documents. These documents are those which have all of the following characteristics:

- The interchange format class used for document interchange is class B (see part 5 of this Standard), consequently the only specific structure present is the specific layout structure.
- The only object types present in the document are document layout root, pages and blocks.
- There is no use of object identifiers in attributes.

In documents adhering to these rules any two consecutive objects of the same object type in the data stream have the same immediate superior. Thus, under these conditions the semantics of the attribute “object identifier” can be transmitted to the recipient implicitly and the attribute need not be explicitly specified.

NOTE 2–6
This exceptional case is provided for compatibility with CCITT Recommendations.

5.3.1.3 Object class identifier

Constituents:
Object class descriptions.

Classification:
Mandatory.

Permissible values:
A sequence of non–negative integers. The values assigned to the first integer are:

- 0 if the constituent is a layout object class description;
- 2 if the constituent is a logical object class description.

Representation:
A character string consisting of decimal numerals and space characters. The decimal numerals are in one to one correspondence with the integers constituting the identifier: a space character is used as a separator between successive numerals.

Definition:
This attribute identifies an object class description uniquely within the context of the document.
An object class identifier consists of a sequence of integers. The first integer in this sequence indicates whether the identifier pertains to a layout object class description or a logical object class description.
An object class identifier consisting of just this first integer identifies an object class description for the document layout root or document logical root. The allocation of the other integers is not constrained, other than that the identifier of each object class must be unique.

5.3.2 Construction attributes

These attributes specify rules for controlling the generation of object descriptions from object class descriptions and for controlling the generation of content.

5.3.2.1 Generator for subordinates

Constituents:
Composite object class descriptions.

Classification:
Non–mandatory.

In the case of a complete generator set of logical object class descriptions, this attribute is mandatory for composite logical object class descriptions. In the case of a complete generator set of layout object class descriptions, this attribute is mandatory for all composite layout object class descriptions except those for lowest level frames, for which it is non–mandatory.

In the case of a factor set of object class descriptions, this attribute shall not be specified.

Permissible values:
A construction expression (see definition below):

Definition:
This attribute specifies which objects, and which combinations of objects, may be immediately subordinate to an object of the class. In addition, this attribute specifies an ordering among these immediately subordinate objects.

The value of this attribute is an expression which can be evaluated in a number of ways to yield a set of possible values. Each value is a sequence of object class identifiers representing a sequence of object classes.

If the attribute is present in a composite object class description within a complete generator set of object class descriptions, then its set of possible values specify a constraint for all objects of the class, restricting the permissible immediately subordinate objects.

If the attribute is present in a composite object class description within a partial generator set of object class descriptions, then it does not constrain the immediately subordinate objects for objects of the class. However, it can be used as a guide for creating or editing the specific structure.

If the attribute is specified, then the constraint, in the case of a complete generator set of object class descriptions, or the guide, in the case of a partial generator set of object class descriptions, is as follows.

Each member of a set of object descriptions which has a common immediate superior has a value for the attribute “object class”. If a sequence is formed consisting of the values of the attribute “object class” for all object descriptions in the set, in the order specified among those object descriptions by the attribute “subordinates” of their common immediate superior, then this sequence must be one of the values that can be generated by the attribute “generator for subordinates” of their common immediate superior.

If the attribute is absent in a composite object class description, then no constraints are specified for the set of immediately subordinate objects of objects of the class.

The value of this attribute consists of a construction expression. A construction expression specifies the identifiers of object class descriptions that can be used to generate immediately subordinate object descriptions of the object description being generated.

A construction expression is either a construction term (see below) or a construction type. A construction type is one of the following:
- a sequence construction, which consists of one or more construction terms, which are to be evaluated in the order specified;
- an aggregate construction, which consists of one or more construction terms, which are to be evaluated in an arbitrary order;
- a choice construction, which consists of one or more construction terms, one of which is to be evaluated.

A construction term is one of the following:
- a required construction factor;
- an optional construction factor;
- a repetitive construction factor;
- an optional repetitive construction factor.

Each construction factor is either an object class identifier or a construction type. In the former case, the value of the construction factor is the object class identifier. In the latter case, the value of the construction factor is derived by evaluation of the construction type. Evaluation of the construction type may produce either an empty sequence or a sequence of one or more object class identifiers.

A required construction factor is to be evaluated once when the containing construction term is evaluated.

An optional construction factor may be evaluated once or may not be evaluated, when the containing construction term is evaluated.

A repetitive construction factor is to be evaluated one or more times in succession when the containing construction term is evaluated.

An optional repetitive construction factor may be evaluated one or more times in succession, or may not be evaluated, when the containing construction term is evaluated.

5.3.2.2 Content generator

Constituents:
Basic object class descriptions, basic logical object descriptions.

Classification:
Non-mandatory.

Permissible values:
A string expression.

Definition:
The value of this attribute is a string expression, which, when evaluated, produces the content associated with the object. String expressions are defined in 5.1.3.1.

When a content generator is specified for a logical object class, it is interpreted as providing the default value for this attribute of the logical object descriptions for objects of that object class.

For any component description, this attribute is ignored if there is more than one content portion or if the single one specifies the attribute "content information".

The attribute "content generator" is evaluated during the layout process and specifies a value for the attribute "content information", the content portion description, if any, is used to specify other content portion attributes.

When a content generator is evaluated, the resulting content is laid out and presented in accordance with the layout directives and presentation attributes applicable.

The content architecture class of the basic component together with the attributes of the content portion, if any, determine how to interpret the string expression. The string expression may represent character content, raster graphics content or geometric graphics content, with type of coding, coding attributes and alternative representation as defined. Any character string literals in a content generator shall pertain to the character set and control functions specified for the particular content architecture class.

5.3.3 Relationship attributes

These attributes specify the relationships between objects, between objects and object classes, between objects and content portions and between objects and presentation styles.

5.3.3.1 Object class

Constituents:
Object descriptions.
Classification:
Non-mandatory.
In the case of a complete generator set of logical object class descriptions this attribute is mandatory for logical object descriptions. In the case of a complete generator set of layout object class descriptions this attribute is mandatory for composite layout object descriptions.
Permissible values:
The identifier of an object class.
Definition:
This attribute is used to establish a relationship between an object description and its object class description.
The value of this attribute is the identifier of the corresponding object class description (see 5.3.1.3).

5.3.3.2 Subordinates
Constituents:
Composite object descriptions.
Classification:
Mandatory, unless the exceptional case described below applies, in which case the attribute is non-mandatory.
Permissible values:
A sequence of one or more non-negative integers.
Definition:
This attribute identifies the set of objects immediately subordinate to the object for which this attribute is specified.
The value of this attribute is a sequence of one or more integers. Each integer corresponds to an immediately subordinate object description and consists of the last integer in the identifier of that subordinate object description (see 5.3.1.2). The sequence contains integers corresponding to each immediately subordinate object description and the same integer may not occur more than once in the sequence.
The order of appearance of the integers in the sequence (not the order of their numeric values) defines the sequential order among the immediately subordinate objects.
In logical object descriptions, the sequential order is interpreted as determining the sequential layout order in which the objects are handled by the layout process. For layout object descriptions, the sequential order is interpreted as determining the imaging order, which is the order in which the immediately subordinate layout objects are overlaid during the imaging process (see 7.1, 7.2), unless overridden by the attribute “imaging order” (see 5.4.3.1).
Exceptions:
This attribute is non-mandatory in certain documents. These documents are those which have all of the following characteristics:
- The interchange format class used for document interchange is class B (see part 5 of this Standard), consequently the only specific structure present is the specific layout structure.
- The only object types present in the document are document layout root, pages and blocks.
- There is no use of object identifiers in attributes.
In documents adhering to these rules any two consecutive objects of the same type in the data stream have the same immediate superior. Thus, under these conditions the semantics of the attribute “subordinates” can be transmitted to the recipient implicitly and the attribute need not be explicitly specified.
The sequential order is defined by the order of appearance in the interchange format, as defined in part 5 of this Standard.
NOTE 2-7
This exceptional case is provided for compatibility with CCITT Recommendations.
5.3.3.3 Content portions

Constituents:
Basic component descriptions.

Classification:
Non–mandatory.

Permissible values:
A sequence of one or more non–negative integers.

Definition:
This attribute specifies which content portions are associated with a component. If more than one content portion is associated with a component then this attribute specifies an ordering among these content portions.

The value of this attribute is a sequence of one or more integers. Each integer corresponds to a content portion of the component concerned and consists of the last integer in the identifier of the content portion description (see 5.9.1). The sequence contains integers corresponding to each content portion of the component concerned and the same integer may not occur more than once in the sequence.

The order of appearance of the integers in the sequence (not the order of their numeric values) defines the sequential order among the content portions.

The sequential order is interpreted as determining the order in which the content portions are handled by the layout and imaging processes.

The attribute must be specified for a basic object description unless at least one of the following applies:

a) the basic object description refers to an object class description which specifies content by one of the following means:
   – by having associated generic content portion descriptions;
   – by specifying a content generator;
   – by referencing an object class description in a resource–document which has associated generic content portion descriptions;

b) the basic object description specifies a content generator, this is only possible in the case of basic logical objects.

Exceptions:
In certain documents this attribute need not be specified for a basic component description even when content portions are associated with the component. These documents are those which have all of the following characteristics:

– The interchange format class used for document interchange is class B (see part 5 of this Standard), consequently the only specific structure present is the specific layout structure.

– The only object types present in the document are document layout root, pages and blocks.

– There is no use of the content portion identifier attributes.

In documents adhering to these rules any two consecutive content portions in the data stream are associated with the same basic object. Thus, under these conditions the semantics of the attribute “content portions” can be transmitted to the recipient implicitly and the attribute need not be explicitly specified.

The sequential order is defined by the order of appearance in the interchange format, as defined in part 5 of this Standard.

*NOTE 2–8
This exceptional case is provided for compatibility with CCITT Recommendations.*

5.3.3.4 Resource

Constituents:
Object class descriptions.

Classification:
Non–mandatory.
Permissible values:
A string of characters from the minimum subrepertoire of ISO 6937–2.

Definition:
This attribute is used to establish a relationship between an object class description in the interchanged document and an object class description in the resource–document (see 2.3.10 and 3.5.9).
The value of this attribute represents the name of an object class description in the resource–document.
The mapping between these names and the object class identifiers within the resource–document is specified by the attribute “resources” in the document profile of the resource–document.

5.3.3.5 Presentation style
Constituents:
Basic component descriptions.
Classification:
Non–mandatory.
Permissible values:
Either a presentation style identifier or ‘null’.
Definition:
This attribute is used to establish a relationship between a basic component description and a presentation style.
If this attribute has the value ‘null’ then no presentation style is referenced from this basic component description.

5.3.4 Content architecture class attributes

5.3.4.1 Content architecture class
Constituents:
Basic component descriptions.
Classification:
Non–mandatory for object class descriptions;
Defaultable for object descriptions.
Permissible values:
An identification of a content architecture class.
Representation:
An ASN.1 object identifier.
Default value:
‘formatted character content architecture’, as defined in part 6 of this Standard.
Definition:
This attribute specifies the content architecture class of the content associated with the basic component.
This attribute identifies the sets of presentation attributes, control functions and coding attributes which are applicable to the content.

5.3.4.2 Content type
Constituents:
Basic layout component descriptions.
Classification:
Non–mandatory for object class descriptions;
Defaultable for object descriptions.
Permissible values:
‘formatted raster graphics content architecture’, as defined in part 7 of this Standard.
Default value:
‘formatted raster graphics content architecture’.

Exceptions:
This attribute provides an alternative to the attribute “content architecture class” as a means to specify the content architecture class of the content associated with the basic component. The attribute follows the same rules for combination with other attributes as are specified in this Standard for “content architecture class”.

This attribute is ignored when a value is specified for the attribute “content architecture class” or, in the case of an object description, when a value of “content architecture class” applies that is derived from any of the steps a) to f) of 5.1.2.4.

NOTE 2-9
This attribute is provided for compatibility with CCITT Recommendations.

5.3.5 Miscellaneous attributes

5.3.5.1 User-readable comments

Constituents:
Component descriptions and styles.

Classification:
Non–mandatory for object class descriptions;
Non–mandatory for styles;
Defaultable for object descriptions.

Permissible values:
A string of characters from a defined character set. The character set is that specified in the document profile attribute “comments character sets”. The default character set is the minimum subrepertoire of ISO 6937–2. In addition to the graphic character set, the control functions carriage return and line feed may be included in the character string. Code extension control functions for the designation and invocation of graphic character sets may also be included.

Default value:
‘empty string’.

Definition:
This attribute consists of a sequence of characters that is to be interpreted as comments relevant to the constituent and to any associated content portions. This character sequence is not part of the document content.

This sequence of characters is intended for use in presentation to humans. The attribute has no significance for the reference models of the layout or imaging processes defined in this part of this Standard, nor for any content layout or imaging processes, defined in other parts of this Standard.

5.3.5.2 Application comments

Constituents:
Component descriptions.

Classification:
Non–mandatory for object class descriptions;
Defaultable for object descriptions.

Permissible values:
An octet string.

Default value:
‘empty string’

Definition:
This attribute shall be used for application dependent comments.
The attribute has no significance for the reference models of the layout or imaging processes defined in this part of this Standard, nor for any content layout or imaging processes, defined in other parts of this Standard.
This character sequence is not part of the document content. It shall be possible to process the document ignoring the value of this attribute.

5.3.5.3 User-visible name

Constituents:
Component descriptions and styles.

Classification:
Non-mandatory for object class descriptions;
Non-mandatory for styles;
Defaultable for object descriptions.

Permissible values:
A string of characters from a defined character set. The character set is that specified in the document profile attribute "comments character sets". The default character set is the minimum subrepertoire of ISO 6937-2. In addition to the graphic character set, the control functions carriage return and line feed may be included in the character string. Code extension control functions for the designation and invocation of graphic character sets may also be included.

Default value:
'empty string'.

Definition:
This attribute consists of a sequence of characters that can be used to identify the constituent within the document structure. This character sequence is not part of the document content.

This sequence of characters is intended for use in presentation to humans. The attribute is intended to assist in the editing of documents, for example to enable a user to directly access an object by name. The attribute has no significance for the reference models of the layout or imaging processes defined in this part of this Standard, nor for any content layout or imaging processes, defined in other parts of this Standard.

This attribute is not intended to be used as an alternative to the identification attributes "object identifier", "object class identifier", "layout style identifier" or "presentation style identifier".

For example, in the case of a logical object class description the value of this attribute may be a name which serves to indicate semantics of the object class to a human, such as "chapter", "section", "paragraph" or "footnote". However, such values are not defined by this Standard.

5.3.5.4 Bindings

Constituents:
Component descriptions.

Classification:
Non-mandatory for object class descriptions;
Defaultable for object descriptions.

Structure:
A set of pairs of parameters, each pair consisting of:
- a "binding name", with a value unique within the set;
- a "binding value".

Permissible values:
For the parameter "binding name", a string of characters from the minimum subrepertoire of ISO 6937-2.

For the parameter "binding value":
- in the case of object class descriptions or logical object descriptions, an expression, which may be a string expression, a numeric expression, or an object identifier expression, as defined in 5.1.3;
- in the case of layout object descriptions, a string literal, a numeric literal, or an object identifier.
Default values:
Each named binding is independently defaultable. For each possible binding name, the
default is that no binding is specified.

Definition:
This attribute specifies a means for determining attribute values. The names specified by the
parameter "binding name" are assigned by the application.
The use of this attribute is restricted to ultimately relate to the value of an attribute.
In this Standard this attribute shall only be used in the evaluation of the content specified by
the attribute "content generator".

5.3.5.5 Default value lists
Constituents:
Composite component descriptions.
Classification:
Non–mandatory.
Structure:
A set of one or more lists of attributes, such that each list applies to a different subordinate
object type.
Within such a set of lists, there should be only one list that pertains to a particular object
type.
Permissible values:
One or more default value lists.

Definition:
This attribute specifies default attribute values for subordinate object descriptions.
Table 2–1 lists the attributes that may be included in a list for each object type.
In the case of a page, if the list applies to a composite page, the attribute "content
architecture class", "content type", "presentation style" and presentation attributes are not
applicable.
When a list applies to a basic object description, then that list may contain one or more
presentation styles or sets of presentation attributes, each corresponding to a different
content architecture class.

5.4 Layout attributes
The attributes defined in this clause are applicable to layout components only.

5.4.1 Property attributes
These attributes specify the characteristics that are applicable to layout components.

5.4.1.1 Position
Constituents:
Frame and block component descriptions.
Classification:
Non-mandatory for object class descriptions;
Defaultable for object descriptions.
Structure:
Either, the parameter "fixed position", which has two sub-parameters: "horizontal position", "vertical position" or, the parameter "variable position", which has four sub-parameters: "offset", "separation", "alignment" and "fill order".
The sub-parameter "offset" is structured into four sub-sub-parameters, "leading offset", "trailing offset", "left-hand offset", "right-hand offset".
The sub-parameter "separation" is structured into three sub-sub-parameters, "leading edge", "trailing edge", "centre separation".

Permissible values:
For the parameter "fixed position":
- "horizontal position": a non-negative integer;
- "vertical position": a non-negative integer.
For the parameter "variable position":
- For the sub-parameter "offset", zero or more of "leading offset", "trailing offset", "left-hand offset", "right-hand offset" can be specified in any instance of this sub-parameter. For each the permissible value is a non-negative integer.
- For the sub-parameter "separation", zero or more of "leading edge", "trailing edge", "centre separation" can be specified in any instance of this sub-parameter. For each the permissible value is a non-negative integer.
- For the sub-parameter "alignment", the permissible values are 'right-hand aligned', 'centred', 'left-hand aligned'.
- For the sub-parameter "fill order", the permissible values are 'normal order', 'reverse order'.

Default values:
If a parameter is specified without including a value for one or more of its sub-parameters or sub-sub-parameters then the following defaults are defined for the unspecified sub-parameters or sub-sub-parameters:
For the parameter "fixed position":
- "horizontal position": 0
- "vertical position": 0
For the parameter "variable position":
- for the sub-parameter "offset":
  - "leading offset": 0
  - "trailing offset": 0
  - "left-hand offset": 0
  - "right-hand offset": 0
- for the sub-parameter "separation":
  - "leading edge": 0
  - "trailing edge": 0
  - "centre separation": 0
for the sub-parameter “alignment”, the default value is ‘right-hand aligned’
for the sub-parameter “fill order”, the default value is ‘normal order’.

**Definition:**

This attribute specifies the position of the object relative to the object at the next higher level in the hierarchical structure (i.e. either the immediately superior page or frame).

Two cases are to be considered, that of fixed position and that of variable position.

In the case of fixed position, the sub–parameters “horizontal position” and “vertical position” correspond to the horizontal and the vertical distances from the reference point of the immediately superior layout object to the reference point of the layout object to which this attribute applies. The position specified must be within the immediately superior layout object. If the immediately superior layout object has a border then the position is further constrained not to fall within the border.

The sub–parameter “horizontal position” specifies the horizontal distance, the sub–parameter “vertical position” specifies the vertical distance. Each of these sub–parameters consists of a non–negative integer, representing the distance concerned as a multiple of scaled measurement units.

The case of variable position may only be specified for frame class descriptions referred to in construction expressions only from other frame class descriptions. Consequently, block component descriptions, frame descriptions and frame class descriptions referred to in construction expressions specified for page class descriptions may only specify fixed position.

In the case of variable position one or more of the sub–parameters “offset”, “separation” “alignment” and “fill order” are specified, as follows:

a) **offset**

This sub–parameter constrains the area within the immediately superior layout object in which the frame can be placed.

The sub–parameter specifies minimum amounts of offset between the boundary of the frame and the boundary of the immediately superior layout object.

The sub–parameter is structured into four sub–sub–parameters, “leading offset”, “trailing offset”, “left–hand offset”, “right–hand offset”. These specify the minimum distance between the corresponding edge of the frame and the leading, trailing, left–hand and right–hand edge of the immediately superior layout object, respectively. (The names of the edges are as defined in 3.3.3.)

For each edge, the sub–sub–parameter specifies the amount of offset for that edge in scaled measurement units.

If the parameter “variable position” does not specify a value for this sub–parameter, or for any of its sub–sub–parameters, then the default value(s) are assumed.

b) **separation**

This sub–parameter specifies minimum amounts of separation between this frame and the nearest adjacent frame immediately subordinate to the same immediate superior layout object. The sub–parameter is structured into three sub–sub–parameters, “leading edge”, “trailing edge”, “centre separation”.

The sub–sub–parameter “leading edge” specifies the minimum separation from the leading edge of the frame and the trailing edge of the next frame laid out in the same fill order.

The sub–sub–parameter “trailing edge” specifies the minimum separation from the trailing edge of the frame and the leading edge of the immediately preceding frame laid out in the same fill order.

Thus, a constraint on the separation of two adjacent frames which both have the same fill order is that the separation must be equal to, or greater than, the greater of the value of “leading edge” for the first of the frames in the direction of layout path and the value of “trailing edge” for the second of the frames.

The sub–sub–parameter “centre separation” specifies the minimum separation between two frames that are laid out with different values for the sub–parameter “fill order”.

Thus, a constraint on the separation of two adjacent frames which have different fill orders is that the separation must be equal to, or greater than, the greater of the values of “centre separation” specified for the two frames.
For each edge, the sub-sub-parameter specifies the amount of separation for that edge in scaled measurement units.
(The names of the edges are as defined in 3.3.3.)
If the parameter "variable position" does not specify a value for this sub-parameter, or for any of its sub-sub-parameters, then the default value(s) are assumed.

c) alignment
This sub-parameter specifies the alignment of the frame within the area available for positioning the frame inside the immediately superior layout object. The alignment is in the direction orthogonal to that specified by the attribute "layout path" of the immediately superior layout object.
This sub-parameter takes one of three values, 'right-hand aligned', 'centred', 'left-hand aligned'.
Subject to satisfying constraints on placement specified by the sub-parameter "offset" and the attribute "border" of the immediately superior layout object, the values of alignment are defined as follows:

1) if the value is 'right-hand aligned' then this frame is to be positioned as close as possible to the right-hand edge of the immediately superior layout object;
2) if the value is 'centred' then this frame is to be centred, in the direction orthogonal to the layout path of the immediately superior layout object, within the area of the immediately superior layout object which is available for positioning the frame;
3) if the value is 'left-hand aligned' then this frame is to be positioned as close as possible to the left-hand edge of the immediately superior layout object.
(The names of the edges are as defined in 3.3.3.)
It is possible to independently align each of a set of sibling frames within their common immediately superior layout object.
If the parameter "variable position" does not specify a value for this sub-parameter then the default value is assumed.

d) fill order
The parameter "fill order" specifies how a frame is to be positioned in its immediately superior layout object relative to the direction of layout path of that object.
The parameter "fill order" takes one of two values, 'normal order' and 'reverse order', defined as follows:

1) If the value is 'normal order' then this frame is grouped together with any sibling frames specifying this value, these frames are positioned after each other in the direction of the layout path of their common immediately superior layout object. The frames in the group are positioned in their sequential layout order, starting at the distance specified by the trailing offset of the first of these frames from the trailing edge of the immediately superior layout object.
2) If the value is 'reverse order' then this frame is grouped together with any sibling frames specifying this value, these frames are positioned after each other in the direction of the layout path of their common immediately superior layout object. The frames in the group are positioned in their sequential layout order, starting at the distance specified by the leading offset of the last of these frames from the leading edge of the immediately superior layout object.
The sub-parameter is applied subject to constraints specified by the parameters "offset" and "separation".
(For the definition of leading and trailing edges see 3.3.3.)
If the parameter "variable position" does not specify a value for this sub-parameter then the default value is assumed.
This attribute is subject to the precedence rule that satisfying constraints on the positioning of other sibling frames which contain any content laid out earlier in sequential logical order than any in this frame, has precedence over satisfying constraints on the positioning of this frame.
5.4.1.2 Dimensions

Constituents:
Page, frame or block component descriptions.

Classification:
Non-mandatory for object class descriptions;
Defaultable for object descriptions.

Structure:
One of two cases applies:
Case 1: The attribute consists of two parameters: "horizontal dimension", "vertical dimension".
The parameter "vertical dimension" includes one of the sub-parameters: "fixed dimension" or "variable page height".
The parameter "horizontal dimension" is represented by a sub-parameter "fixed dimension".
Case 2: The attribute consists of two parameters: "horizontal dimension", "vertical dimension".

Each parameter includes one of the four sub-parameters: "fixed dimension", "Rule A", "Rule B" and "maximum size".
The sub-parameters "Rule A" and "Rule B" include two optional sub-sub-parameters "minimum dimension", "maximum dimension".

Permissible values:
Case 1:
- "horizontal dimension":
- "fixed dimension": positive integer;
- "vertical dimension": one of two sub-parameters:
- "fixed dimension": positive integer;
- "variable page height": any integer (see exception case);
Case 2:
- "horizontal dimension": one of four sub-parameters:
- "vertical dimension": one of four sub-parameters:
- "fixed dimension": positive integer;
- "Rule A": 'applies', with two optional sub-sub-parameters:
- "minimum dimension": positive integer,
- "maximum dimension": positive integer;
- "Rule B": 'applies', with two optional sub-sub-parameters:
- "minimum dimension": positive integer,
- "maximum dimension": positive integer;
- "maximum size": 'applies'.

Default values:
Each of the parameters is independently defaultable.
For a frame or block: "horizontal dimension", "vertical dimension" both with the sub-parameter "fixed dimension", with a value that is the maximum size that can be achieved for the position within the area of the immediately superior object.
For a page: "horizontal dimension", "vertical dimension" both with the sub-parameter "fixed dimension", with a value that is the assured reproduction area for ISO A4 (see 7.3)

Definition:
In either case, this attribute consists of an ordered pair of parameters, corresponding to the dimensions in the horizontal and vertical directions of the component in scaled measurement units. The first parameter of the pair specifies the dimension in the horizontal direction, the second parameter specifies the dimension in the vertical direction.
Case 1:
The parameter “horizontal dimension” is represented by a sub-parameter “fixed dimension”, the parameter “vertical dimension” is either represented by a sub-parameter “fixed dimension” or “variable page height”, defined as follows:
- “fixed dimension”: specifies the dimension concerned in scaled measurement units;
- “variable page height”: specifies that the vertical dimension is undetermined.

Case 2:
Each parameter includes one of the four sub-parameters, “fixed dimension”, “Rule A”, “Rule B” and “maximum size”, defined as follows:

a) “fixed dimension”: specifies the dimension concerned in scaled measurement units.

b) “Rule A”: specifies that the dimension concerned is to be the minimum size necessary for the frame to contain that immediately subordinate frame or block which has the associated content that is earliest in sequential logical order. The dimension acts as a constraint on the dimensions in the same direction of all other immediately subordinate frames or blocks.

c) “Rule B”: specifies that the dimension concerned is to be the minimum size necessary for the frame to contain all the immediately subordinate frames or blocks.

d) “maximum size”: specifies that the dimension concerned is to take its default value.

By the use of the sub-parameters in a), b) and c), each dimension of a frame can have either a fixed size or a variable size.

Rule A and Rule B may only be specified for frame class descriptions referred to in construction expressions only from other frame class descriptions. Consequently, block and page component descriptions, frame descriptions and frame class descriptions referred to in construction expressions specified by page class descriptions may not specify these rules. Further, Rule A may only be specified for the dimension in same direction as the layout path of the immediately superior frame.

In the case of “Rule A” or “Rule B”, two further sub-sub-parameters can optionally be specified.
- “minimum dimension”;
- “maximum dimension”.

These sub-sub-parameters specify a constraint on the dimensions determined by the rule. If the value determined by the rule would otherwise be smaller than the value of “minimum dimension” then the value will be that specified by “minimum dimension”. If the value determined by the rule would otherwise be larger than the value of “maximum dimension” then the value will be that specified by “maximum dimension”.

The minimum and maximum dimensions are specified in scaled measurement units.

In all cases the dimensions for frame and block components are constrained to be no greater than the maximum size which can be contained within the immediately superior frame or page (given the position of the frame or block and the direction of the layout path). If the immediately superior layout object is a frame which has a border then the dimensions are further constrained such that no part of the frame or block falls within the border. Note that this maximum size is the default value for the attribute.

Exceptions:
The sub-parameter “variable page height” may only be specified for basic page components, and for the vertical dimension only.

NOTE 2–10
The sub-parameter “variable page height” is provided for compatibility with existing CCITT Recommendations.

5.4.1.3 Border

Constituents:
Frame and block component descriptions, presentation styles

Classification:
Non-mandatory for object class descriptions;
Non-mandatory for presentation styles;
Defaultable for object descriptions.
Structure:
Zero or more of the parameters “left-hand-edge”, “right-hand-edge”, “trailing-edge” and “leading-edge”.
Each parameter either has the value ‘null’ or consists of zero or more of the sub-parameters “border line width”, “border line type”, “border freespace width”.
Permissible values:
For each of the four parameters:
- ‘null’;
or, a combination of:
- "border line width": any non-negative integer
- "border freespace width": any non-negative integer
Default values:
For each of the four parameters:
- "border line width": 20
- "border line type": ‘solid’
- "border freespace width": 0
Definition:
This attribute specifies a border, consisting of a border line and border freespace, for the edges of a frame or block component (see 3.3.5). Each of the four parameters determines that the corresponding block or frame edge is to be highlighted by the presence of a border.
The border line is described by specifying its width in scaled measurement units and its line type. The border freespace is described by specifying its width in scaled measurement units.
In the case of a block, the border is outside the edges of the block and the border freespace provides a region which surrounds the block between the block boundary and the border line.
In the case of a frame, the border is inside the edges of the frame and the border freespace provides a region which is within the frame between the frame boundary and the border line.
If the parameter for a particular edge has the value ‘null’ then no border should be drawn for the edge.

5.4.2 Formatting attributes
These attributes specify the information applicable to the formatting of the document.

5.4.2.1 Balance
Constituents:
Composite layout component descriptions without immediately subordinate blocks.
Classification:
Non–mandatory for layout object class descriptions;
Defaultable for layout object descriptions.
Permissible values:
In the case of a layout object description, either ‘null’ or a sequence of two or more layout object identifiers.
In the case of an layout object class description, either ‘null’ or a sequence of two or more layout object class identifiers.
Default value:
‘null’.
Definition:
This attribute specifies that the leading edges of a set of immediately subordinate layout objects shall, as far as possible, be aligned along a line orthogonal to the direction of the layout path.
In the case of a layout object description, the value of this attribute is either ‘null’ or a sequence of two or more identifiers of immediately subordinate object descriptions.

In the case of a layout object class description, the value of this attribute is either ‘null’ or a sequence of two or more identifiers of layout object class descriptions for composite layout objects. The layout object class description is also required to specify the attribute “generator for subordinates” which shall be able to generate a sequence of object class identifiers which correspond one–for–one and in sequence to the sequence of object class identifiers specified by this attribute. If these requirements are not satisfied then the attribute balance should be ignored.

All object descriptions and object class descriptions identified by this attribute must have the same value for layout path and the same set of “permitted categories”. If the same value for layout path or the same set of permitted categories are not specified then the attribute balance should be ignored.

The value ‘null’ indicates that no constraints on the sizes of the subordinate layout objects are specified by this instance of this attribute.

5.4.2.2 Layout path

Constituents:
Frame component descriptions.

Classification:
Non–mandatory for object class descriptions;
Defaulterable for object descriptions.

Permissible values:
A set of data elements defined for the attribute, ‘0°’, ‘90°’, ‘180°’, ‘270°’.

Default value:
’270°’.

Definition:
In the case of lowest–level frames this attribute specifies the direction of progression of the allocation of any immediately subordinate blocks during the layout process, relative to the horizontal direction.

In the case of higher–level frames this attribute specifies the direction of progression of the allocation of any immediately subordinate frames with variable positions during the layout process, relative to the horizontal direction.

This attribute has no meaning in the case of immediately subordinate frames or blocks with fixed positions.

For a frame for which the object class defines variable dimensions, the layout path influences the determination of these dimensions, as described for the attribute “dimensions”.

5.4.2.3 Logical source

Constituents:
Frame object class descriptions.

Classification:
Non–mandatory.

Permissible values:
An object class identifier for a logical object class description.

Definition:
This attribute is specified for a layout object class if the content associated with each of the layout objects of that class is to be supplied by a logical object class, for example, the content associated with a header or footer frame on a page.

The attribute identifies the logical object class description concerned.

The effect of the attribute is that an instance of an object of the specified logical object class, and all its subordinates, if any, is created automatically whenever an instance of an object of the layout object class is generated during the layout process.
If the logical object class description specifies the attribute "generator for subordinates", the construction expression it contains is evaluated, causing the creation of one or more subordinate logical objects. This step is then repeated for the logical object class descriptions corresponding to these subordinate objects. If any of the logical object class descriptions specifies the attribute "content generator" then the expression in this attribute is evaluated. The attribute "generator for subordinates" specified by the logical object class description, if any, shall only contain construction terms which consist of required construction factors, or sequence constructions which use only required construction factors. The same rule applies to logical object class descriptions for all subordinate objects.

The content associated with the created logical object(s) is then laid out entirely within the layout object, as if the logical object class identified had specified the attribute "layout object class" referring to the layout object class concerned.

The logical object that is automatically created and its subordinates, if any, are not added to the specific logical structure and are not interchanged as a part of the document. However, the layout object and its subordinates and content are added to the specific layout structure. The content portion descriptions added to the specific layout structure shall contain the attribute "content identifier - layout" and shall not contain the attribute "content identifier - logical".

5.4.2.4 Permitted categories

Constituents:
Lowest level frame component descriptions.

Classification:
Non-mandatory for object class descriptions;
Defaultable for object descriptions.

Permissible values:
Either 'null' or one or more strings of characters from the minimum subrepertoire of ISO 6937-2, each being the name of a layout category

Default value:
'null'.

Definition:
This attribute specifies the layout categories permitted for logical objects the content of which is to be laid out within the frame.

A layout category has a name which may be associated with lowest level frame component descriptions and with basic logical component descriptions in order to specify and restrict the layout objects into which the content associated with basic logical objects may be placed.

A frame can specify any number of layout categories. The content associated with a basic logical object is constrained to be placed within frame(s) that specify the same layout category as that specified by the logical object. This provides for the layout process to consist of a number of separate layout streams (see section 6).

The value of this attribute is the set of names of the layout categories permitted.

This attribute is only significant for lowest level frames. If the attribute is specified for a frame which has frame(s) as subordinates then the attribute is ignored, i.e. permitted layout categories are not cumulative.

If the attribute value is 'null', the content associated with logical objects of any layout category is permitted to be placed in the frame, including content associated with logical objects which do not specify a layout category.

5.4.3 Imaging attributes

These attributes specify the information applicable to imaging the document.

5.4.3.1 Imaging order

Constituents:
Composite page or frame object descriptions.

Classification:
Non-mandatory.
Permissible values:
A sequence of one or more non-negative integers.

Definition:
This attribute specifies the precedence for imaging of the immediately subordinate layout objects.
The value of this attribute is a sequence of one or more integers. Each integer corresponds to an immediately subordinate object description and consists of the last integer in the identifier of that subordinate object description (see 5.3.1.2). The sequence contains integers corresponding to each immediately subordinate object description and the same integer may not occur more than once in the sequence.
The order of appearance of the integers in the sequence (not the order of their numeric values) defines the imaging order among the immediately subordinate objects.
The imaging order determines how the image of the document is resolved for displaying on a presentation surface. In the definition of the reference imaging process it determines the order in which the immediately subordinate layout objects are overlaid during the imaging process. The use in combination of the attributes “imaging order”, “transparency” and “colour” is described in 7.2.
If a value is not specified for this attribute, the imaging order is the same as the sequential layout order, as specified by the attribute “subordinates” (see 5.3.3.2).

5.4.3.2 Transparency
Constituents:
Page, frame or block component descriptions, presentation styles.
Classification:
Non-mandatory for object class descriptions;
Non-mandatory for presentation styles;
Defaultable for object descriptions.
Permissible values:
A set of data elements defined for the attribute, ‘transparent’, ‘opaque’.
Default value:
‘transparent’.
Definition:
This attribute defines the transparency of a page, frame or block.
When two or more frames and/or blocks intersect, the effect of combination is determined from the imaging order, as described in 7.1.
Transparency is in effect only when blocks and/or frames actually intersect. The use in combination of the attributes “imaging order”, “transparency” and “colour” is described in 7.2.

5.4.3.3 Colour
Constituents:
Page, frame or block component descriptions, presentation styles.
Classification:
Non-mandatory for object class descriptions;
Non-mandatory for presentation styles;
Defaultable for object descriptions.
Permissible values:
A set of data elements defined for the attribute, ‘colourless’, ‘white’.
Default value:
‘colourless’.
Definition:
This attribute defines the colour of a page, frame or block.
The value 'white' shall only be specified if the attribute "transparency" has the value 'opaque'.

When two or more frames and/or blocks intersect, the effect of combination is determined from the imaging order, as described in 7.1. The use in combination of the attributes "imaging order", "transparency" and "colour" is described in 7.2.

5.4.3.4 Page position
Constituents:
Page component descriptions.
Classification:
Non–mandatory for object class descriptions;
Defaultable for object descriptions.
Permissible values:
A pair of non–negative integers.
Default value:
Such that edge losses are minimised.
Definition:
This attribute specifies the position of the layout object page within a nominal page (see 7.3). The value of this attribute is an ordered pair of integers that specify the horizontal and vertical distances from the top left corner of the nominal page to the reference point of the layout object page, in scaled measurement units.
The first integer of the pair specifies the horizontal distance, the second specifies the vertical distance.
The use of this attribute is further described in 7.3.

5.4.3.5 Medium type
Constituents:
Page component descriptions.
Classification:
Non–mandatory for object class descriptions;
Defaultable for object descriptions.
Structure:
Two parameters, "nominal page size" and "side of sheet".
Permissible values:
For the parameter "nominal page size": a pair of positive integers.
For the parameter "side of sheet", a set of data elements defined for the parameter, 'recto', 'verso', 'unspecified'.
Default values:
The two parameters are independantly defaultable.
The default values are:
- "nominal page size" : dimensions for ISO A4 (see section 7);
- "side of sheet" : 'unspecified'.
Definition:
This attribute defines the type of presentation media that is to be used for imaging the page. The parameter "nominal page size" identifies the particular nominal page size that is to be used. This parameter specifies the horizontal and vertical dimensions of the nominal page, in scaled measurement units. The first integer of the pair specifies the horizontal dimension, the second specifies the vertical dimension.
The parameter "side of sheet" indicates the side of a sheet on which the page is to be imaged or indicates that this is unspecified.
The use of this attribute is described further in section 7.
5.4.4 Presentation attributes

Constituents:
Basic page or block component descriptions, presentation styles.

Classification:
Non–mandatory for object class descriptions;
Non–mandatory for presentation styles;
Defaultable for object descriptions.

Permissible values:
Any set of presentation attributes applicable to a particular content architecture class, as defined in those parts of this Standard which specify the individual content architectures.

Default values:
The individual presentation attributes are independantly defaultable.

Definition:
A number of sets of presentation attributes may be specified. Which set applies to a given basic component depends on the content architecture class of the content associated with the component.

5.5 Logical attributes

The attributes defined in this clause are applicable to logical components only.

5.5.1 Protection

Constituents:
Logical component descriptions

Classification:
Non–mandatory for object class descriptions;
Defaultable for object descriptions.

Permissible values:
A set of data elements defined for the attribute, 'protected', 'unprotected'.

Default value:
'unprotected'.

Definition:
This attribute specifies whether or not the logical object, and any associated content portions, are intended to be protected from having any attributes modified by the recipient.

Default value:
'unprotected'.

Definition:
This attribute specifies whether or not the logical object, and any associated content portions, are intended to be protected from having any attributes modified by the recipient.
If the attribute is specified for a composite logical component description, then it is applicable only to that description. If the attribute is specified for a basic component description, then it is applicable to that description and all content portions referred to from that description.

5.5.2 Layout style

Constituents:
Logical component descriptions.

Classification:
Non–mandatory.

Permissible values:
A layout style identifier or 'null'.

Definition:
This attribute is used to establish a relationship between a logical component and a layout style.
If this attribute has the value ‘null’ then no layout style is referenced from this logical component description.

5.6 Layout style attributes

5.6.1 Layout style identifier

Constituents:
Layout styles.
Classification:
Mandatory.
Permissible values:
A sequence of two non-negative integers, the first of which is always ‘4’.
Representation:
A character string consisting of two decimal-coded numerals with a space character as a separator between the numerals.
Definition:
This attribute identifies a layout style uniquely within the context of the document.

5.6.2 Attributes which can be specified for layout styles

The following attributes can be specified for layout styles:
- layout style identifier (see 5.6.1);
- user-readable comments (see 5.3.5.1);
- user-visible name (see 5.3.5.3);
- layout directive attributes (see 5.7);

Apart from the attribute “layout style identifier”, which is mandatory for layout styles, the attributes are non-mandatory for layout styles.

The attributes “user-readable comments” and “user-visible name” are used to describe the style itself and are not referenced by the defaulting mechanism for the purpose of determining values for attributes of the same name for object descriptions.

5.7 Layout directives

A layout directive is an attribute of a layout style which guides the generation of a layout structure from a logical structure.

Layout directives are characterised as follows:
- they apply to a logical component as a whole and cannot be changed within the content;
- they are content architecture independent;
- during the layout process, they affect the creation and position of layout objects (see section 6 for a specification of the reference document layout process).

Some of the attributes may be applied only to basic logical component descriptions, some only to composite logical component descriptions and some in both cases. The applicability to logical object types and the default value for each attribute is specified in the individual attribute definitions under “constituents”.

Layout directives are applied subject to their conforming to the layout object class descriptions.

5.7.1 Block Alignment

Constituents:
May be specified for layout styles;
applicable only to basic logical component descriptions.
Classification:
Non-mandatory when specified for layout styles;
Non-mandatory when applied to logical object class descriptions;
Defaultable when applied to logical object descriptions.
Permissible values:

Default value:
‘right-hand aligned’.

Definition:
This attribute specifies the alignment of the block(s) used to present the content associated with this logical object within the available area(s) (see 2.4.2), subject to satisfying constraints on placement specified by the attribute “offset” (see 5.7.8). The alignment specified by this attribute is in the direction perpendicular to that specified by the attribute “layout path” of the lowest level frame(s) containing the block(s).

The value of this attribute specifies the alignment relative to the direction of layout path.

When the attribute “layout path” specifies 270°, ‘right-hand aligned’ means that the block(s) will appear left aligned on the presentation medium within the available area(s). ‘left-hand aligned’ means that the block(s) will appear right aligned on the presentation medium within the available area(s), and ‘centred’ means that the block(s) will appear centred on the presentation medium, within the available area(s).

A ‘null’ value indicates that no constraints on the layout of the logical object are specified by this instance of the attribute.

5.7.2 Concatenation

Constituents:
May be specified for layout styles;
applicable only to basic logical component descriptions.

Classification:
Non–mandatory when specified for layout styles;
Non–mandatory when applied to logical object class descriptions;
Defaultable when applied to logical object descriptions.

Permissible values:
A set of data elements defined for the attribute, ‘concatenated’, ‘non–concatenated’.

Default value:
‘non–concatenated’.

Definition:
This attribute specifies whether or not the content associated with a basic logical object to which it applies and the content associated with an earlier basic logical object in the logical sequential order which has the same content architecture class, layout category and fill order, are to be concatenated. That is, the attribute indicates whether the content associated with the object and the earlier object are to be treated as an unbroken stream. There may be other logical objects between the two in sequential logical order, but these must not specify the same content architecture class, layout category and fill order.

The value ‘concatenated’ specifies that the layout of the content associated with the component must if possible be continued in the same basic layout object as used with the content associated with the earlier basic logical component in sequential logical order that has the same value of the attributes “content architecture class”, “layout category” and “fill order”.

The value ‘non–concatenated’ specifies that the content associated with the logical component should be laid out starting in a new basic layout object.

Each content architecture specifies in the relevant part of this Standard whether or not the function of concatenation can be applied to content of that content architecture.

In the case of any content architecture for which concatenation can be applied, the rules for concatenation as they affect presentation attributes are included in the definition of that content architecture.
5.7.3 Fill order
Constituents:
May be specified for layout styles;
applicable only to basic logical component descriptions.
Classification:
Non–mandatory when specified for layout styles;
Non–mandatory when applied to logical object class descriptions;
Defaultable when applied to logical object descriptions.
Permissible values:
A set of data elements defined for the attribute,
‘normal order’, ‘reverse order’.
Default value:
‘normal order’.
Definition:
This attribute specifies how the block(s) containing content associated with this logical object are
to be laid out within their immediately superior layout object, relative to the direction of layout
path of that superior object.
The value ‘normal order’ specifies that the blocks are to be positioned after each other in the
direction of layout path, in the sequential logical order of the logical objects whose content they contain.
These blocks are positioned starting from the trailing edge of the immediately superior layout
object, subject to constraints specified by other layout directive attributes.
The value ‘reverse order’ specifies that the blocks are to be positioned after each other in the
direction of layout path, in the sequential logical order of the logical objects whose content they contain.
These blocks are positioned ending at the leading edge of the immediately superior layout
object, subject to constraints specified by other layout directive attributes.
(For the definition of leading and trailing edges see 3.3.3.)

5.7.4 Indivisibility
Constituents:
May be specified for layout styles;
applicable to all logical component descriptions except the document logical root.
Classification:
Non–mandatory when specified for layout styles;
Non–mandatory when applied to logical object class descriptions;
Defaultable when applied to logical object descriptions.
Permissible values:
One of the following:
a) the identifier of a layout object class description;
b) the identifier of a layout category;
c) ‘object type page’;
d) ‘null’.
Default value:
‘null’.
Definition:
This attribute specifies that the content associated with the logical object shall if possible be laid
out within a single layout object which is of a specified object class or layout category or object
type.
This attribute does not restrict the layout of other logical objects within the same layout object.
If the value is as in a) above, the layout object must be of the specified layout object class, this
must be of object type page set, page or frame.
If the value is as in b) above, the layout object must be of the specified layout category.
If the value is as in c) above, the layout object must be of object type page.
A ‘null’ value indicates that no constraints on the layout of the logical object are specified by this instance of this attribute.

5.7.5 Layout category

Constituents:
May be specified for layout styles;
applicable only to basic logical component descriptions.

Classification:
Non–mandatory when specified for layout styles;
Non–mandatory when applied to logical object class descriptions;
Defaultable when applied to logical object descriptions.

Permissible values:
Either ‘null’ or a string of characters from the minimum subrepertoire of ISO 6937–2, this being a layout category identifier.

Default value:
‘null’.

Definition:
This attribute specifies the name of the layout category of the logical object.
A layout category is a name which may be associated with basic logical component descriptions and with frame component descriptions in order to specify and restrict the layout objects into which the content associated with basic logical objects may be placed.
A logical component can specify only a single layout category. The content associated with a logical object is constrained to be placed within frame(s) that include the name of this layout category in the list of such names specified by the attribute “permitted categories”.
The content associated with logical objects to which the same layout category applies is laid out such that the sequential layout ordering of the content is the same as its sequential logical ordering.
The content associated with logical objects to which different layout categories apply may be laid out such that the sequential layout ordering of the content is different from its sequential logical ordering.
Thus, the effect of using more than one layout category within a specific logical structure is to divide the content into different layout streams (see 6.3.1), each layout stream pertaining to a particular layout category.
The content associated with more than one basic logical object may be laid out in the same frame, whether their layout categories are the same or different, provided that the frame specifies matching layout categories for each of the logical objects.
Also, the content associated with basic logical objects which have the same layout category may be laid out in frames generated from different layout object classes, providing that each frame specifies a matching layout category.
If the attribute value is ‘null’, then the logical object does not specify any layout category and the associated content is only permitted to be laid out into frames for which no permitted categories have been specified, i.e. for which the attribute “permitted categories” has the value ‘null’.

5.7.6 Layout object class

Constituents:
May be specified for layout styles;
applicable to all logical component descriptions.

Classification:
Non–mandatory when specified for layout styles;
Non–mandatory when applied to logical object class descriptions;
Defaultable when applied to logical object descriptions.

Permissible values:
An identifier of a layout object class description, or ‘null’.
Default value:

'null'.

Definition:

This attribute specifies the class of a layout object into which the content associated with this logical object and all its subordinates is to be laid out. The content must be laid out within a single instance of a layout object derived from the referenced layout object class, and no other part of the content of the document may be laid out within the same layout object.

This attribute may only be used to specify layout object classes of object type document layout root, page set, page or frame.

This attribute can be applied to logical objects at any hierarchical level within the logical structure. It is valid for this attribute to apply to a logical object when the attribute also applies to one or more superior logical objects. The constraints specified by the attributes in such cases are cumulative.

In every such case, the layout object into which the content associated with a subordinate logical object is placed must be a subordinate of the layout object into which a superior logical object is placed. Consequently, the generic structure is required to be such that objects of the layout object class specified by the subordinate can be generated within objects of the layout object class specified by the superior. If this attribute is not present on any superior logical object, then there is no restriction on the layout object class specified by this attribute.

The attribute "layout object class" takes precedence over "layout category". Thus, when a composite logical object has the attribute "layout object class", the layout categories applicable to subordinate basic logical objects are only valid within the layout sub-structure subordinate to the layout object corresponding to the specified "layout object class". However, the semantics of the attribute "layout category" are not overridden, it is required that the layout categories of basic logical objects match those of the frames into which they are placed.

A 'null' value indicates that no constraints on the layout of the logical object are specified by this instance of this attribute.

5.7.7 New layout object

Constituents:

May be specified for layout styles;
applicable to all logical component descriptions except the document logical root

Classification:

Non-mandatory when specified for layout styles;
Non-mandatory when applied to logical object class descriptions;
Defaultable when applied to logical object descriptions.

Permissible values:

One of the following:

a) the identifier of a layout object class description;

b) the identifier of a layout category;

c) 'object type page';

d) 'null'.

Default value:

'null'.

Definition:

This attribute specifies that the content associated with the logical object shall be laid out starting within the next layout object (from a current layout position, see below) which does not contain any content associated with preceding logical objects, and which is of a specified layout object class or layout category or object type.

The current layout position in the specific layout structure is that of the basic layout object in which was laid out the end of the content associated with the preceding logical object with the same layout category as:

- for a basic logical object, the object for which the attribute is specified;
- for a composite logical object, the first basic logical object in sequential logical order subordinate to the logical object for which this attribute is specified.
In the case that no preceding logical object had the same layout category, the current layout position is the document layout root.

If the value is as in a) above, the next layout object must be of the specified layout object class, this must be of object type page set, page or frame.

If the value is as in b) above, the next layout object must be of the specified layout category.

If the value is as in c) above, the next layout object must be of object type page.

A 'null' value indicates that no constraints on the layout of the logical object are specified by this instance of this attribute. That is, the content associated with the logical object is to be laid out starting at the current layout position, if possible.

5.7.8 Offset

Constituents:
May be specified for layout styles;
applicable only to basic logical component descriptions.

Classification:
Non–mandatory when specified for layout styles;
Non–mandatory when applied to logical object class descriptions;
Defaultable when applied to logical object descriptions.

Structure:
Four parameters, “leading offset”, “trailing offset”, “left–hand offset”, “right–hand offset”.

Permissible values:
For each parameter, a non–negative integer.

Default value:
Each of the four parameters is independently defaultable.
The default for each parameter is: 0.

Definition:
This attribute constrains the available area (see 2.4.2) within the immediately superior frame or page in which the content associated with the basic logical object can be placed.

This attribute specifies minimum amounts of offset between the boundary of a block used to present the content associated with this logical object and the boundary of the immediately superior layout object.

The parameters “leading offset”, “trailing offset”, “left–hand offset”, “right–hand offset” specify the minimum distance between the corresponding edge of the block containing the content associated with this logical object and the leading, trailing, left–hand and right–hand edge of the immediately superior layout object, respectively.

(The names of the edges are as defined in 3.3.3.)

For each edge, the corresponding parameter specifies the amount of offset for that edge in scaled measurement units.

5.7.9 Same layout object

Constituents:
May be specified for layout styles;
applicable to all logical component descriptions except the document logical root.

Classification:
Non–mandatory when specified for layout styles;
Non–mandatory when applied to logical object class descriptions;
Defaultable when applied to logical object descriptions.

Structure:
The value of this attribute consists of two parameters.

Permissible values:
With regard to the first parameter:
– when this attribute is applied to a logical object description, the value is the identifier of another logical object description, or ‘null’;
when this attribute is applied to a logical object class description, the value is an object identifier expression, or 'null'.

If the first parameter has the value 'null' then the second parameter is ignored, otherwise the value of the second parameter shall be one of:
   a) the identifier of a layout object class description;
   b) the identifier of a layout category;
   c) 'object type page';

**Default value:**
First parameter: ‘null’; second parameter: ignored.

**Definition:**
This attribute specifies that the start of the content associated with the logical object and the end of the content associated with another logical object, specified by the first parameter, shall be laid out, if possible, within a single layout object which is of a specified layout object class or layout category or object type, as specified by the second parameter.

If this cannot be fulfilled, then the start of the content associated with the logical object shall be laid out in the earliest layout object in sequential layout order which:
  - follows the layout object in which the end of the content associated with the specified logical object is laid out;
  - is of the specified layout object class, layout category or object type;
  - permits the layout of the start of the content associated with the logical object.

The current layout position of all layout streams pertaining to the layout categories that apply to the logical object, and its subordinates, if any, for which the attribute applies are moved forward to the beginning of the layout object identified by the second parameter. Any layout stream with current layout position within or after the layout object identified by the second parameter is not affected.

If the value is as in a) above, the layout object must be of the specified layout object class, this must be of object type page set, page or frame.

If the value is as in b) above, the layout object must be of the specified layout category.

If the value is as in c) above, the layout object must be of object type page.

A 'null' value of the first parameter indicates that no constraints on the layout of the content associated with the logical object are specified by this instance of this attribute.

### 5.7.10 Separation

**Constituents:**
May be specified for layout styles;
applicable only to basic logical component descriptions.

**Classification:**
Non–mandatory when specified for layout styles;
Non–mandatory when applied to logical object class descriptions;
Defeatable when applied to logical object descriptions.

**Structure:**
Three parameters, “leading edge”, “trailing edge”, “centre separation”.

**Permissible values:**
For each parameter, a non–negative integer. One or more of the parameters can be specified in any instance of this attribute.

**Default values:**
Each of the three parameters are independently defeatable. The default value for each parameter is: 0.

**Definition:**
This attribute specifies minimum amounts of separation between the block(s) used to lay out the content associated with the basic logical object and the nearest adjacent block(s) immediately subordinate to the same immediate superior layout object.
The parameter “leading edge” specifies the minimum separation from the leading edge of the last block containing content associated with this logical object and the trailing edge of the next block laid out in the same fill order.

The parameter “trailing edge” specifies the minimum separation from the trailing edge of the first block containing content associated with this logical object and the leading edge of the closest preceding block laid out in the same fill order.

Thus, a constraint on the separation of two adjacent blocks which both have the same fill order is that the separation must be equal to, or greater than, the greater of the value of the parameter “leading edge” for the logical object with content laid out in the first of the blocks in the direction of layout path and the value of the parameter “trailing edge” for the logical object with content laid out in the second of the blocks.

The parameter “centre separation” specifies the minimum distance between two objects within a frame that are laid out with opposite fill order – ‘normal order’ and ‘reverse order’.

Thus, a constraint on the separation of two adjacent blocks which have different fill orders is that the separation must be equal to, or greater than, the maximum of the value of the parameter “centre separation” specified for the logical objects with content laid out in the two blocks.

For each edge, the parameter specifies the amount of separation for that edge in scaled measurement units.

(The names of the edges are as defined in 3.3.3.)

5.7.11 Synchronization

Constituents:
May be specified for layout styles;
applicable to all logical component descriptions except the document logical root.

Classification:
Non–mandatory when specified for layout styles;
Non–mandatory when applied to logical object class descriptions;
Defaultable when applied to logical object descriptions.

Permissible values:
When this attribute is specified for a logical object description, the value is either the identifier of another logical object description, or ‘null’.
When this attribute is specified for a logical object class description or in a layout style, the value is either an object identifier expression, or ‘null’.

Default value:
‘null’.

Definition:
This attribute specifies that the content associated with the component and with another specified component are to be laid out aligned along a line orthogonal to the direction of the layout path.

When the attribute specifies a reference to another logical object, the trailing edge of the first block containing content associated with that other logical object and the trailing edge of the first block containing content associated with the logical object to which the attribute applies should be synchronized, i.e. the lines along the trailing edges coincide.

The two blocks containing the beginning of the content associated with the two logical objects involved must be placed into distinct lowest level frames. The direction of fill order for these blocks must be the same, and the direction of layout path must be the same in these frames for this attribute to be in effect. If not, this attribute will be ignored. The frames may have the same or different layout categories and may be on the same or different pages.

The value ‘null’ indicates that no constraints on the layout of the content associated with the logical object are specified by this instance of this attribute.

5.7.12 Interactions and precedences among the layout directives

This sub–clause describes the order in which the different layout directives are to be taken into account in the layout process.
The interactions and precedences described here provide a general implementation guideline, but are not intended to be taken as a complete formal specification of the interaction resolution mechanism. They are not intended to represent an actual implementation, nor to restrict in any way the processing that may be applied to an interchanged document.

It is assumed that a document which is defined in accordance with this Standard can be laid out in accordance with the rules described below. That is, it is assumed that each attribute pertaining to the layout process can be interpreted in accordance with the definition of that attribute. It is outside the scope of this Standard to indicate how a document containing conflicting or inconsistent information is to be laid out.

For composite logical objects the following layout directive attributes are applicable, listed in the order of decreasing precedence:
- layout object class;
- new layout object;
- same layout object;
- synchronization;
- indivisibility.

This set of layout directives should not only be taken into account at a particular level but also at hierarchically related levels. This means that each layout directive applicable to a lower level logical object description should result in a valid layout as defined by the layout directives applicable to logical object descriptions higher in the hierarchy. That is, a layout directive applicable to logical object descriptions higher in the hierarchy has precedence over any layout directives applicable to logical object descriptions at lower levels.

For basic logical objects the following layout directive attributes are applicable, listed in the order of decreasing precedence:
- layout object class;
- layout category;
- new layout object;
- same layout object;
- fill order;
- concatenation;
- offset;
- separation;
- synchronization;
- indivisibility;
- block alignment.

The layout directives applicable to basic logical object descriptions should also be valid within the set of layout directives applicable to superior logical object descriptions.

There follows a description of the individual layout directives in order of decreasing precedence:

a) layout object class

The specification made by this attribute should be given highest precedence.

When this attribute specifies a lowest level frame, then the following attributes are ignored:
- new layout object;
- same layout object;
- indivisibility.

b) layout category

The specification made by this attribute should be fulfilled.

c) new layout object.

The specification made by this attribute should be fulfilled if the attribute "layout object class" does not apply to this logical object.

When the attribute "layout object class" is applied to this logical object and the layout object of that class is of the kind specified by the attribute "new layout object", then the specification made by this attribute is automatically fulfilled. Otherwise a subordinate of the object of that class should fulfill the specification.
If the attribute “layout object class” has specified a lowest level frame for this or a superior logical object, then this attribute should be ignored.

d) same layout object
   The specification made by this attribute should be ignored when:
   - the end of the content associated with the referenced logical object is laid out in a layout object not belonging to the class or category specified;
   - the attribute “layout object class” has specified a lowest level frame for this or a superior logical object:
   - the attribute “new layout object” has specified an object class, object type or layout category which can not be a subordinate to the layout object specified by this attribute.
   - it would require content to be laid out outside a layout object specified by the attribute “layout object class” applicable to this object or one of its superiors;
   - it would require content to be laid out within a layout object which is specified by the attribute “layout object class” applicable to an object which is neither a superior nor a subordinate of the object for which the attribute is specified.

e) fill order
   The specification made by this attribute should be fulfilled.

f) concatenation
   When this attribute specifies the value ‘non–concatenated’, the specification made by this attribute should be fulfilled.

   When this attribute specifies the value ‘concatenated’, the specification made by this attribute should be ignored and the content associated with the logical component should not be concatenated if either of the following conditions apply:
   - the closest preceding basic logical object in logical sequential order which has the same layout category and fill order does not have the same content architecture class as this logical object;
   - the attribute “layout object class” or the attribute “new layout object” also applies to the component.

   In addition, the content need not be concatenated if this is necessary in order to satisfy the attribute “balance”.

   If none of the preceding conditions apply then the content associated with the logical object should be concatenated if there is adequate available area.

   The attributes “separation”, “offset”, “border”, “colour”, “transparency”, and “block alignment”, are ignored when the content associated with the logical object is concatenated.

   The attribute “indivisibility” and the attribute “same layout object” may be used in conjunction with the attribute “concatenation”.

  g) offset
   The specification made by this attribute should be fulfilled except when the attribute is applied to basic logical objects that are concatenated to preceding logical objects.

  h) separation
   The specification made by this attribute should be fulfilled except when the attribute is applied to basic logical objects that are concatenated to preceding logical objects.

  i) synchronization
   When this attribute specifies a value other than ‘null’, the specification should be fulfilled provided that all conditions for synchronization are possible without violating any layout directives of higher precedence.

  k) indivisibility
   When this attribute specifies a value other than ‘null’, the specification should be fulfilled provided that all conditions for indivisibility are possible without violating any layout directives of higher precedence.

  l) block alignment
   The specification made by this attribute should be fulfilled except for the part of the content associated with the logical object which is concatenated with the content associated with another logical object.
The attribute is applied subject to satisfying constraints on placement specified by the attribute "offset".

5.7.13 Interactions among attributes affecting the layout process

All layout directives affect the document layout process. This is also true for some of the attributes of the generic layout structure.

Similarly to the layout directive attribute "layout category" the specifications made by the attribute "permitted categories" should be fulfilled.

When the layout process requires the creation of a new composite layout object, its creation is controlled by the attribute "generator for subordinates".

The specification made by the attribute "balance" should be fulfilled without violating any of the layout directives.

The specification made by the attribute "layout path" is used for determining the sides specified in the attributes "fill order", "offset", "separation" and "block alignment". It is also used by the layout directive attribute "synchronization" as well as the layout attributes "position", "dimensions" and "balance".

The attribute "border" can also constrain the position and dimensions of layout objects. The attributes "transparency" and "imaging order" have no effect on the creation of layout objects, nor do they effect their position and dimensions.

5.8 Presentation style attributes

5.8.1 Presentation style identifier

Constituents:
Presentation styles.

Classification:
Mandatory.

Permissible values:
A sequence of two non-negative integers, the first of which is always '5'.

Representation:
A character string consisting of two decimal-coded numerals with a space character as a separator between the numerals.

Definition:
This attribute identifies a presentation style uniquely within the context of the document.

5.8.2 Attributes which can be specified for presentation styles

The following attributes can be specified for presentation styles:
- presentation style identifier (see 5.8.1);
- user-readable comments (see 5.3.5.1);
- user-visible name (see 5.3.5.3);
- presentation attributes (see 5.4.4);
- border (see 5.4.1.3);
- transparency (see 5.4.3.2);
- colour (see 5.4.3.3).

Apart from the attribute "presentation style identifier", which is mandatory for presentation styles, the attributes are non-mandatory for presentation styles.

The attributes "user-readable comments" and "user-visible name" are used to describe the style itself and are not referenced by the defaulting mechanism for the purpose of determining values for attributes of the same name for object descriptions.

All attributes in presentation styles apply only to basic component descriptions. The attributes "border", "transparency" and "colour" can only apply to blocks when specified in a presentation style. (Such a reference can be either direct, if the presentation style is referred to by a layout component, or indirect, if the presentation style is referred to by a logical component.)
5.9 Content portion attributes

The attributes defined in this clause are applicable to content portions only.

5.9.1 Identification attributes:
Content identifier – logical;
Content identifier – layout

Constituents:
Content portion descriptions.

Classification:
Each of the attributes individually is non-mandatory. At least one of the attributes shall be specified for every content portion description, unless the exceptional case described below applies.

Structure:
A pair of attributes.

Permissible values:
For each attribute, a sequence of non-negative integers.

Representation:
For each attribute, a character string consisting of decimal numerals and space characters. The decimal numerals are in one to one correspondence with the integers constituting the identifier: a space character is used as a separator between successive numerals.

Definition:
These attributes identify a content portion description uniquely within the context of the document and are used to refer to that content portion description.

These attributes are used in the context of relationships to content portions (see 5.3.3.3).
The value of each attribute consists of a sequence of integers, as defined in 5.3.1.2 and 5.3.1.3 for an identifier of a basic component, with an additional integer to identify the content portion uniquely among the set of content portions that are associated with the relevant basic component.

A content portion description in the specific structure can specify one or both attributes.
The attribute “content identifier – layout” is specified when the content portion is associated with a basic layout object. The attribute “content identifier – logical” is specified when the content portion is associated with a basic logical object.

A generic content portion description can have only one identifier attribute, according to whether the content portion is associated with a layout object class or a logical object class.

When a document is reformatted any content portion descriptions that are associated with the specific layout structure only are deleted. The content portions which are deleted are any that specify the attribute “content identifier – layout” and do not specify the attribute “content identifier – logical”.

Exceptions:
This attribute is non-mandatory in certain documents. These documents are those which have all of the following characteristics:

- The interchange format class used for document interchange is class B (see part 5 of this Standard), consequently the only specific structure present is the specific layout structure.
- The only object types present in the document are document layout root, pages and blocks.
- There is no use of identifiers of content portions in attributes.

In documents adhering to these rules any two consecutive content portions in the data stream are associated with the same basic object. Thus, under these conditions the semantics of the content identifier attributes can be transmitted to the recipient implicitly and the attribute need not be explicitly specified.

NOTE 2–11
This exceptional case is provided for compatibility with CCITT Recommendations.
5.9.2 Common coding attributes:
Type of coding
Constituents:
Content portion descriptions.
Classification:
Defaultable.
Permissible values:
ASN.1 object identifier.
Representation, Default values:
The definition of particular values is specified in those parts of this Standard that deal with individual content architectures.
Definition:
This attribute specifies the coding used to represent the content, and designates any set of additional coding attributes applicable to the content portion concerned (see 5.9.4).
Exception case:
The value is also permitted to be an integer in the case of formatted raster graphics content architecture.

 NOTE 2-12
This exceptional case is provided for compatibility with CCITT Recommendations.

5.9.3 Content information attributes

5.9.3.1 Content information
Constituents:
Content portion descriptions
Classification:
Non–mandatory.
Permissible values:
An octet string.
Representation:
Defined in those parts of this Standard that deal with individual content architectures.
Definition:
This attribute specifies that part of the content portion description which is composed of content elements (for example, graphic characters, pixels) governed by a content architecture.

5.9.3.2 Alternative representation
Constituents:
Content portion descriptions
Classification:
Non–mandatory.
Permissible values:
A string of characters from a defined character set.
Definition:
This attribute specifies a sequence of characters that may be imaged in lieu of the attribute “content information” when a receiver of the document is not capable of decoding and/or imaging the content portion.
The character set to be used in this attribute is that specified in the document profile attribute “alternative representation character sets”.
The default character set is the minimum subrepertoire of ISO 6937–2.
In addition to the graphic character set, the control functions carriage return and line feed may be included in the character string.
5.9.4 Coding attributes

Constituents:
Content portion descriptions

Classification, Structure, Permissible values, Representation, Default values:
Defined in those parts of this Standard that deal with individual content architectures.

Definition:
These attributes are related to the type of coding of the content portion and provide additional parametric information used in encoding/decoding the content portion.

6. REFERENCE MODEL OF THE DOCUMENT LAYOUT PROCESS

This section provides a description of the document layout process as applicable to documents which contain a specific logical structure, a complete generic layout structure and optionally layout styles, presentation styles, and/or a generic logical structure.

The content layout process, which controls the layout of content portions within basic layout objects is not described here but in those parts of this Standard relating to particular content architectures.

6.1 Overview

The document layout process consists of the automatic generation of a specific layout structure for a document and the layout of the content of basic logical objects into blocks within lowest level frames in this specific layout structure. During this process the basic logical objects are considered in accordance with their sequential order in the specific logical structure.

The reference model of the document layout process only handles layout into frames, it does not handle the case of documents containing basic pages.

The document layout process is carried out in accordance with the values of the layout directive attributes applicable to the logical object descriptions representing the specific logical structure.

In effect, layout directives express relationships between objects in the specific logical structure and object classes in a generic layout structure.

The specific layout structure which is generated is consistent with the generic layout structure and is in accordance with the layout directive attributes applicable to the logical object descriptions and the logical object class descriptions.

In all cases when attributes of logical component descriptions or layout component descriptions have values which are specified by expressions these values are evaluated by the layout process.

Each time a logical object is considered for layout, any applicable attributes which are specified by expressions are evaluated. Each time a layout object is created, any applicable attributes which are specified by expressions are evaluated.

The document layout process involves the creation of a sequence of page sets, pages and frames into which the content of the sequence of basic logical objects is to be laid out. The document layout process controls the allocation of the areas within a frame or sequence of frames into which the content of each basic logical object is to be placed and defines constraints on the area(s) into which the content may be laid out. The document layout process determines when the layout objects which have been created are closed from further use for layout.

The content layout process is responsible for formatting the content into the allocated area taking into account the constraints imposed by the document layout process. The content and document layout processes are together responsible for the creation of basic layout objects.

The content layout process determines the dimensions of the basic layout objects. The document layout process is responsible for determining the position of these basic layout objects within their immediately superior layout objects. The document layout process is also responsible for determining the dimensions and positions of frames.

This can be performed by two different mechanisms. When frames have fixed dimensions and positions, a top down approach is made resulting in areas available for positioning blocks. When values for dimensions and positions of frames are specified by rules or expressions, i.e. non-fixed values, a bottom up approach is taken in defining the dimensions and positions based on the dimensions of basic layout objects. This latter approach is constrained from a top down specification of permissible ranges.

All frames and blocks immediately subordinate to a page are specified with fixed positions and dimensions.
All frames with the same immediate superior frame are either specified with fixed positions or specified with non-fixed positions.

All blocks with the same immediate superior frame are either specified with fixed positions and dimensions, i.e. from the generic layout structure, or with non-fixed positions and dimensions, i.e. content dependent.

It is assumed that a document which is defined in accordance with this Standard can be laid out in accordance with the rules described below. That is, it is assumed that each attribute pertaining to the layout process can be interpreted in accordance with the definition of that attribute. It is outside the scope of this Standard to indicate how a document containing conflicting or inconsistent information is to be laid out.

6.2 Content and layout structure generation

The generation of the specific layout structure is controlled by the complete generic layout structure. The construction rules for creation of page sets, pages and frames that are required for the layout of a particular specific logical structure are specified in the generic layout structure. The only basic layout objects for an automatic layout process are blocks. These are created in one of two ways:

- Firstly, blocks may be created as a result of a layout process laying out the content associated with basic logical components without the use of a layout object class description of object type block.
- Secondly, blocks may be created from a layout object class description of object type block; such a block class description must specify content, either in the form of generic content portion(s) or by use of the attribute “content generator”.

The layout process creates a specific layout structure, which conforms to the complete generic layout structure and which accommodates all the content of the document.

6.2.1 Laying out content of a document

For the layout process, content of a document can be either related to the specific logical structure or to the generic layout structure.

In the generic structures, the content associated with an object class description may be specified by the attribute “content portions” and contained in one or more generic content portions identified by that attribute. Alternatively, the content may be specified by the attribute “content generator”, in which case the content is derived from the string expression that is the value of that attribute.

The value of a content generator is determined during the layout process. The evaluation of the expression which specifies the value of the attribute occurs when the content portion is laid out. If the expression refers to other expressions, then these are also evaluated at this point.

6.2.1.1 Content related to the specific logical structures

The content related to the specific logical structure can occur in the following forms:

a) content in a content portion that is directly referenced by a basic logical object;

b) content in a generic content portion that is associated with a basic logical object class in a generic logical structure or resource–document;

c) content specified by the attribute “content generator” that is specified for the basic logical object;

d) content specified by the attribute “content generator” that is specified for a basic logical object class in a generic logical structure or resource–document.

In all cases, the content may be either in processable, formatted or formatted processable form.

If case a) applies, the document layout process causes the creation of a basic layout object that references the same content portion referenced by the basic logical object. This is achieved by adding the attribute “content identifier – layout” to the content portion description. As a result, the content portion will be common to both the specific logical and specific layout structures.
In some cases, the content portion associated with the single basic logical object will cause the generation of two or more basic layout objects. For example, a part of the content may be laid out at the end of one frame and the remainder of the content in the next frame. In this case, the content portion will be divided into two or more content portions such that the basic logical object now references a sequence of two or more content portions, each of which is referenced by only one of the basic layout objects which have been created.

On the other hand, in some cases no new layout object needs to be created because the attribute “concatenation” has been specified for the specific logical object. In this case, the corresponding basic layout object references a sequence of two or more content portions. If the basic logical object derives its content information from content information in a generic object class, as in case b), then the document layout process causes the generation of a new content portion that is only associated with the specific layout structure. That is, this new content portion is only referenced by the basic layout object produced during the document layout process.

In cases c) and d), the attribute “content generator” has to be evaluated before being laid out by the document layout process. As in case b), the document layout process results in the creation of a new content portion that is only associated with the specific layout structure. If in these cases the basic logical object directly references a content portion (containing no content information) then no change is made to that content portion.

6.2.1.2 Content related to the generic layout structure

The content related to the generic layout structure can occur in the following forms:

a) content in a generic content portion that is associated with a basic layout object class description in the generic layout structure or resource–document;

b) content specified by the attribute “content generator” to be applied to a basic object class description in the generic layout structure or resource–document;

c) content specified in the generic logical structure that is referred to from the generic layout structure (application of “logical source”);

In case a), the content portion is already formatted and the position and dimensions of the block containing it are specified in the layout object class of object type block. The document layout process will use these. The specific layout objects containing this content, which can be many, will only have a reference to the generic layout object class description with the generic content portion and no additional content portions will be generated.

In case b), the attribute has to be evaluated by the layout process before being laid out by the layout process. The evaluated content may be in processable, formatted or formatted processable form. The evaluation will result in a content portion that is only associated with the specific layout structure.

In case c), on the creation of a layout object of a class that has the attribute “logical source” (see 5.4.2.3), an instance of the logical object and its content, if any, of the class specified by that attribute, and its subordinates if it is a composite object, is generated.

In order for the layout process to be deterministic the attribute “generator for subordinates” for this logical object class and also for all of its subordinates is only allowed to specify a construction expression composed from construction terms consisting only of required construction factors and/or sequence constructions, which use only required construction factors.

The created logical object, or hierarchy of logical objects, is not added to the specific logical structure.

The resulting logical objects and associated content portions are then laid out in accordance with the document layout process. In order to lay out this content one or more layout objects and their associated content portions are added to the specific layout structure being generated by the document layout process.

This is done in a way that the created logical objects are entirely laid out within the layout object that caused their creation (as if the attribute “layout object class” had been specified for the root of the created tree of logical objects).

The created content portions are only associated to the specific layout structure.
6.2.1.3  **Reformatting of content of a formatted processable form document**

If a document is reformatted then all components in the specific layout structure are first deleted, together with all its content portions that are not common to both the specific logical and specific layout structures. All occurrences of the attribute “content identifier – layout” are also removed from the content portions associated with the specific logical structure. In addition, any content portions that were divided as a result of the document layout process are recombined into a single content portion.

The reformattting is then performed as described for initial formatting in 6.2.1.1 and 6.2.1.2.

6.2.2  **Specific layout structure generation**

The process of creating the specific layout structure is governed by the attribute “generator for subordinates” (see 5.3.2.1) which is applicable to layout object class descriptions and which guides and restricts the layout sub–structures, if any, that may be generated immediately subordinate to layout objects of that class.

This attribute contains a construction expression which specifies the immediately subordinate objects that may be generated when that layout object class is used and in what order these subordinate objects may be generated. The immediate subordinates of a composite layout object are created in the sequential layout order specified by the construction expression. The construction expression indicates whether or not each subordinate object is required, is optional, has a choice, and if it can be repeated more than once.

Construction expressions are evaluated as described in 5.3.2.1.

The result will be a hierarchic specific layout structure with a well defined sequential layout order that can serve as input to an imaging process.

6.3  **Layout references and categories**

There are two principal methods of controlling the generation of a specific layout structure from the logical structure, and the allocation of the content of basic logical objects to layout objects within that layout structure; one is provided by layout categories, the other by layout references.

6.3.1  **Layout categories**

A layout category can be specified by the attribute “layout category” (see 5.7.5), which applies to basic logical object descriptions, and by the attribute “permitted categories” (see 5.4.2.4), which applies to frames at the lowest level in any branch of the layout structure. The layout process ensures that the content of basic logical objects of any layout category is only placed into frames which specify a matching layout category.

The effect of specifying different layout category identifiers for different basic logical objects is to partition those objects into different layout streams, each of which corresponds to a particular layout category. These different layout streams are laid out into sequences of frames having appropriate layout category identifiers. The content of logical objects of the same layout stream is laid out such that the order of the content within the specific layout structure is the same as its order within the specific logical structure.

However, the order in which the basic logical objects are laid out by the layout process is still in accordance with their sequential logical order, irrespective of the layout category that applies.

As the layout is created by sequentially processing the logical objects the layout process maintains a current layout position, which identifies an object of the specific layout structure, for each layout stream which occurs.

When the layout process commences, the current layout position of all layout streams is at the root of the specific layout structure.

When laying out the first content of a particular layout stream, and whenever a new frame is needed for the content of a particular layout stream, then the layout process searches the layout structure for the earliest lowest level frame in sequential layout order which already exists, or can be created, and includes the layout category of the layout stream in its permitted categories and satisfies other constraints that may be present due to attributes of the logical and layout structures. The search for such a frame starts from the layout object identified by the current layout positions. When a suitable lowest–level frame has been identified, the current layout position of the layout stream is moved forward to this frame.
The layout process processes the basic logical objects of the document in the order in which they occur in the sequential logical order by placing the content of each such object into a block within the lowest level frame at the current layout position of the layout stream identified by the layout category of that logical object.

When the content of a logical object is split by the layout process into several layout objects, this above layout of content is repeated, as in the preceding description, for each part of the content, possibly with intervening searches for a new current layout position.

The current layout position of one or more layout streams may also be moved forward in the sequential layout order in order to satisfy a layout directive such as “new layout object.”

The current layout position of a layout stream is never moved backwards in the sequential layout order. In cases in which the content of a basic logical object is concatenated to that of another basic logical object which is not its immediate predecessor within the layout stream (for example, where an intermediate object specifies different fill order or content architecture attributes), then some of this content may be laid out within existing layout objects from which the current layout position has previously been moved forward.

However, backtracking to satisfy layout directives such as “balance”, “synchronization”, “indivisibility” and “same layout object” may cause the layout for the part of the layout structure that is in the scope of the directive and of interacting directives to be reconsidered, moving all the current layout positions that were in this part back to its beginning. Each of the cases in which this may occur is explicitly mentioned in the description of the layout process for the layout directive that may cause this backtracking.

Content that is not derived from the specific logical structure (i.e. content specified by the attribute logical source or by a content rule of the layout structure) does not form part of the layout streams of the specific logical structure. This content is laid out when the current layout position of any layout stream passes the layout object in sequential layout order to which the content rule or the logical source attribute, respectively, applies. If necessary this content is laid out when the end of the layout process is reached.

The layout process places no constraints on the layout object class descriptions which specify the permitted category, thus the content of basic logical objects may be laid out in frames generated by different layout object class descriptions, provided that each frame specifies the appropriate layout category identifier.

In the case that frames specify multiple permitted categories then the current layout position of more than one layout stream can identify the same lowest level frame, thus in such cases basic logical objects with different layout category identifiers may be laid out in the same frame.

If a lowest level frame specifies no permitted categories ('null' value), then the layout process treats it as if it had specified all layout categories, in the sense that such a frame will satisfy the search for a new current layout position for any layout stream. Thus basic logical objects of any layout category may be laid out in such a frame.

If a basic logical object has no specified layout category, then it is allocated to a separate layout stream maintained for this purpose, the layout process will lay it out only in lowest level frames which specify no permitted categories.

The use of different layout streams is illustrated in Figure 2-13.

In this example, each page contains frames of permitted category 'a' and 'b'. If the next basic logical object has category 'a' then its content will be laid out in the left hand frame of page 3. The content associated with the next basic logical object of category 'b' will be laid out in the right hand frame of page 1.
Figure 2–13 – Illustration of layout streams
From this example, it can be seen that the document layout process does not close portions of the specific layout structure for further layout when creating a new layout object. That is, the creation of pages 2, 3 etc., and the frames within those pages does not prevent frame ‘b’ in page 1 from being used for the layout of subsequent basic logical objects of category ‘b’.

Thus frame ‘b’ in page 1 is the current layout position for laying out the content of the next basic logical object of category ‘b’; and frame ‘a’ in page 3 is the current layout position for basic logical objects of category ‘a’.

In subsequent clauses it is shown how some additional attributes impose additional constraints concerning the frame in which a basic logical object is laid out.

If a layout object class has been specified for a basic logical object or any of its superiors, then the constraint specified by the layout object class should be satisfied when laying out a basic logical object into a frame.

When a composite logical object specifies a layout object class, then a layout object, of the object class identified by the attribute “layout object class”, should be created by the layout process to contain the all the content associated with all the subordinates of the composite logical object. Layout categories applicable to subordinate basic logical objects are only valid within the layout sub-structure subordinate to this layout object.

Both a layout object class and a layout category may be specified for a basic logical object and in this case both attributes must be satisfied when carrying out the layout process.

6.3.2 Layout object class

The layout reference is specified by the layout directive attribute “layout object class” (see 5.7.6) which identifies a layout object class description. When processing a logical object description specifying this attribute the layout process creates a layout object of the specified layout object class.

The content of the logical object, or if it is a composite object the content of all of its subordinate basic objects, is entirely laid out within this single layout object. No other part of the document is laid out within this layout object.

Thus, the layout process closes this layout object and all of its subordinates from use for further layout as soon as the logical object that specified the attribute, and all of its subordinates, have been laid out.

This attribute could be used, for example, to indicate that each chapter in a document must be laid out in an instance of a particular page set.

6.4 The effect of some attributes on the document layout process

In addition to the constraints imposed by the attributes “layout object class” and “layout category” on the document layout process, a number of other attributes impose additional constraints on this process. This clause describes the effect of some of these, namely:

- new layout object;
- same layout object;
- indivisibility;
- synchronization;
- balance;

6.4.1 New layout object

The attribute “new layout object” (see 5.7.7) is used to control the layout process such that the content associated with the logical object with which the attribute is associated, should be laid out at the beginning of a particular instance of a layout object. It specifies that the content of the first affected layout stream should be laid out in a layout object, which does not contain any preceding content. In addition it also synchronizes a set of layout streams.

Examples of use are that a section should start on a new page; a figure at the beginning of a frame, or a particular paragraph at the top of a column.

The layout process determines the current layout position of the first affected layout stream. This stream is the first encountered layout stream in the sequential logical order in the logical object for which the attribute “new layout object” applies.
Starting from this current layout position, the layout process determines or creates the next layout object in the sequential layout order of the specified object class, layout category or object type, which does not contain any content associated with any logical objects preceding, in the sequential logical order, the logical object with the content to be laid out.

If the current position is found to be in a layout object fulfilling these criteria, no new layout object of specified layout object class, layout category or object type need be created. Otherwise the layout process has to create such an object according to the rules of the generic layout structure.

If a layout object is found or created fulfilling the criteria of the attribute “new layout object”, the current layout position for all layout streams specified by the logical object or its subordinates are moved forward in the sequential layout order to this layout object. These current layout positions are moved before any content of these layout streams belonging to the logical object or its subordinates are laid out.

In acting on an instance of this attribute, the layout process only finds or creates one layout object of the specified layout object class, layout category or object type and this only for the first affected layout stream.

As an illustration, consider in figure 2–13 the case in which the first affected layout stream is of layout category ‘b’ and the attribute “new layout object” specifies a layout object of layout category ‘b’ or a layout object of object type ‘page’, the content of the layout stream ‘b’ will be laid out in the right hand frame of page 2 or page 4, respectively.

If the attribute has specified an object of the object class corresponding to the right hand frame or to the page, the content of the layout stream ‘b’ will also be laid out in the right hand frame of page 2 or page 4, respectively.

6.4.2 Same layout object

The attribute “same layout object” is used to control the layout process such that the content associated with the logical object with which the attribute is associated and the content associated with another specified logical object, is laid out within a particular layout object. It specifies that the beginning of the content of the logical object for which the attribute applies should be laid out in the same layout object of a specified object class, layout category or object type as the end of the content of a referenced logical object. In addition it also synchronizes a set of layout streams.

A typical use of this attribute is to control the layout process such that a footnote should start on the same page as its reference.

The layout process requires that the logical object referred to shall precede, in the sequential logical order, the logical object for which the attribute applies.

The synchronization aspect of this attribute moves the current layout positions of all layout streams of the logical object for which the attribute applies, forward in the sequential layout order to the layout object specified by the attribute. These current layout positions are moved before any content of these layout streams belonging to the logical object or its subordinates are laid out. Any layout stream with current layout position within or after the specified layout object is not affected.

The layout process determines the layout position of the end of the content of the referenced logical object and the current layout position of the content to be laid out. If these two layout positions are both within the same layout object of specified object class, layout category or object type, the effect of this attribute is fulfilled.

If this should not be the case, the layout of the content of several logical objects may be modified so as to satisfy this attribute. The reference layout process does not identify any particular algorithms by which the layout may be modified so as to satisfy the constraint specified by this attribute. However, for each layout stream (layout category), the sequential layout order must not be changed, i.e. it must correspond to the sequential logical order.

6.4.3 Indivisibility

The attribute “indivisibility” is used to control the layout process such that the content associated with the logical object with which the attribute is associated, is laid out within a particular layout object. It specifies that all content associated with the logical object for which the attribute applies should be laid out in the same layout object of a specified object class, layout category or object type.
Typical uses of this attribute are to control the layout process such that a figure and the whole figure caption should be laid out on the same page; that a certain paragraph must not be split by a column break or page break; or that two paragraphs should be laid out completely on the same page.

The layout process determines if the current layout positions of all affected layout streams are within the same layout object of specified object class, layout category or object type, and that all content of the affected layout streams that belongs to the logical object (if basic) or to the subordinates of the logical object (if composite), for which the attribute applies can be laid out completely within that layout object. If this is the case, then this attribute is fulfilled.

If this should not be the case, the layout of the content of several logical objects may be modified so as to satisfy this attribute. The reference layout process does not identify any particular algorithms by which the layout may be modified. However, for each layout stream (layout category), the sequential layout order must not be changed, i.e. it must correspond to the sequential logical order.

If the current layout positions of all affected layout streams are not within a layout object for which the attribute can be fulfilled, this attribute moves the current layout positions of all affected layout streams of the logical object for which the attribute applies, forward in the sequential layout order to the layout object specified by the attribute. These current layout positions are moved before any content of these layout streams belonging to the logical object or its subordinates are laid out.

### 6.4.4 Synchronization

The attribute "synchronization" is used to control the layout process such that the logical object with which the attribute is associated, and another specified logical object have their content laid out in different blocks with trailing edges aligned along a line. It specifies that the block containing the beginning of the content of the logical object or, if composite, its subordinates for which the attribute applies should be laid out with its trailing edge along the line of the trailing edge of the block containing the beginning of the content of the logical object or, if composite, its subordinates of the logical object referred to in the attribute.

A typical use of this attribute is for synchronization of multi-lingual multi-column text, where the start of each paragraph or sub-section is horizontally aligned. Another use is for synchronization of pictures (eg mirror pictures) on different pages or columns.

Two conditions are necessary for this attribute to be in effect, namely:

- The referenced logical object must precede in the sequential logical order the logical object for which the attribute applies.

- The two different lowest level frames to which the two blocks involved are subordinate, must have the same layout path, i.e. they must have the same value of the attribute “layout path”.

The layout process determines if these conditions are fulfilled. If this is not the case, the attribute will be ignored. If this is the case, however, the reference layout process does not identify any particular algorithms by which the layout may be modified. However, for each layout stream/layout category the sequential layout order must not be changed, i.e. corresponds to the sequential logical order. If the content of each of the logical objects to be synchronized is not concatenated to content of previous logical objects, the layout process would normally:

- either move the block containing the beginning of the content of the logical object, if basic, or of its first subordinate, if composite, for which the attribute applies such that its trailing edge is aligned with the trailing edge of the block containing the beginning of the content of the logical object, if basic, or of its first subordinates, if composite, referred to;

- or, alternatively it will move the block or blocks containing the content of the referred logical object or its subordinates forward in the direction of layout path such that the attribute can be fulfilled.

If the content of either or both of the logical objects is concatenated with content of a previous logical object then the reference layout model does not specify an exact algorithm for the point at which synchronization occurs.

In the case that both the attribute “synchronization” and the attribute “fill order” with value ‘reverse order’ have been applied to a logical object, the reference layout process outlined does not specify an exact algorithm.
6.4.5 Balance
The attribute “balance” is used to control the layout process such that the content in a specified set of layout objects contains appropriate amount of content such that the leading edge of each layout object specified should be approximately along a single line.
A typical use of this attribute is for balancing multi-column text at the end of a section.
The attribute only applies to those object or object class descriptions in which it is specified if these correspond to objects which only have composite layout objects as its immediate subordinates. Thus the attribute does not apply when specified in a component description of a lowest level frame.
The layout process determines if all conditions for this attribute are fulfilled (see 5.4.2.1). If this is not the case, the attribute will be ignored.
In the case that the conditions are fulfilled, the layout process does not identify any particular algorithms by which the layout may be modified. However, for each layout stream (layout category), the sequential layout order must not be changed, i.e. corresponds to the sequential logical order. Normally, the layout process will move content from the layout objects earlier in the sequential layout order to those later in the specified set in order to “balance” the content so that their leading edges will be approximately aligned.

6.5 Layout process for frames
In the layout process, the placement of frames within superior layout objects is controlled by means of the layout attributes “position” and “dimensions”.
The positioning of frames within their immediately superior layout object is determined in one of two ways, corresponding to the two methods of specifying the attribute positions.
a) a constant position;
b) a position derived from evaluation of a rule.
Frames immediately subordinate to a page are specified at constant positions.
The immediate subordinates of any frame are either all positioned at constant positions or all positioned using values derived from evaluation of a rule. The layout of blocks within a frame is described in clause 6.6. The two cases for layout of frames within a superior frame are described in this clause.
If a frame specifies the attribute “border” then the position and dimensions of immediately subordinate frames are constrained to be such that no part of any of these frames falls within the border region of their immediate superior.
In the case that the attribute “border” is specified, then for each edge the border allowance is the sum of the “border line width” and “border freespace width” for the frame. If a border is not specified for one or more of the edges, then for these edges the border allowance is 0 SMUs. The border allowances for the four edges form the border allowance of the frame, which constrains the area available to the layout process for placement of immediately subordinate frames.

6.5.1 Placement of frames with fixed position
In the case of frames placed at a fixed position, the value of the attribute “position” in the frame class description is a constant value for both of the sub-parameters “horizontal position”, “vertical position”. If either of the sub-parameters “horizontal position”, “vertical position” is not specified then it assumes the default value.
In the case in which such a frame has variable dimensions, the area available to the layout process for the placement of immediately subordinate frames may be further constrained by the specified fixed position.
The dimensions of a fixed position frame are not constrained by other frames subordinate to the same immediately superior layout object.

6.5.2 Placement of frames with variable position
In the case of placement of frames at a position determined by a rule, the value of the attribute “position” in the frame class description specifies the four sub-parameters “alignment”, “fill order”, “offset” and “separation”. These sub-parameters specify constraints on the placement of the frame which are used to uniquely determine the position of the frame.
In this case the layout of frames is also controlled by means of the layout attribute “layout path” (see 5.4.2.2) of the immediately superior frame, which specifies a reference direction for the positioning of immediately subordinate frames.

The reference model for the layout process for variably positioned frames assumes that placement of the variably positioned immediate subordinates of a frame occurs in their sequential layout order.

6.5.2.1 Determination of the area for placement of frames

The area within a frame for the placement of immediately subordinate frames is determined by the border allowance of the frame and the sub-parameters “fill order”, “offset” and “separation” of the immediately subordinate frames.

In all cases the area for placement of a frame is constrained to be both within the border allowance and also within the region defined to satisfy the sub-parameter “offset” of the frame to be placed. For each edge, the greater of the border allowance and the offset for the edge, specified by the relevant one of the sub-sub-parameters “trailing offset”, “leading offset”, “left offset” and “right offset” determines the constraint on the area for placement within the immediately superior frame.

Two cases must be taken into account, as described in 6.5.2.1.1 and 6.5.2.1.2.

6.5.2.1.1 Placement of frames in normal order

If there is no other frame currently within the immediately superior frame, then no additional constraints to those already described (i.e. border and offset) are specified.

If there already exist one or more frames laid out in normal order in the immediately superior frame, then the sub-parameter “separation” is used to additionally constrain the distance between the leading edge of the last laid out frame and area available for placement. That distance is constrained to be no less than the maximum of:

- the value of the sub-sub-parameter “leading edge” for the last laid out frame;
- the value of the sub-sub-parameter “trailing edge” for the frame to be laid out.

If there already exist one or more frames laid out in ‘reverse order’ in the immediately superior frame then the sub-sub-parameter “centre separation” of the sub-parameter “separation” is used to additionally constrain the distance between the area available for placement and the trailing edge of the first of the frames placed in reverse order. The distance is constrained to be no less than the maximum of:

- the value of the sub-sub-parameter “centre separation” for the first frame placed in reverse order;
- the value of the sub-sub-parameter “centre separation” for the frame to be placed;

In all cases, the frame is positioned as close to the trailing edge of the immediately superior frame as is possible under these constraints and those specified in 6.5.2.1.

6.5.2.1.2 Placement of frames in reverse order

For placement of frames in reverse order, the reference model for the layout process operates in three steps:

a) Additional constraints are determined depending on the values of the sub-parameter “fill order” for the immediate subordinates of the immediately superior frame. Determining these constraints may involve temporarily re-positioning some of these subordinates.

b) For the purpose of determining the constraints on its dimension, the frame is temporarily positioned as close to the trailing edge of the immediately superior frame as is possible under these constraints and those defined in 6.5.2.1.

c) Finally, all frames laid out in reverse order are re-positioned as far as possible in the direction of the layout path, without violating the border allowance of the immediately superior frame or the sub-parameters “offset” and “separation” specified for the various frames.

The details of step a) (determination of additional constraints) are:

- If there is no other frame currently within the immediately superior frame, then no additional constraints to those described in 6.5.2.1 (i.e. border and offset) need to be considered.
If, within the immediately superior frame, there exist one or more frames laid out in reverse order but none in normal order then, for the purpose of calculating the size of the area available for placement, the frames already present are temporarily positioned as far as possible in the direction opposite to the layout path, without violating the border allowance or the sub-parameters “offset” and “separation” specified for the various frames. The sub-parameter “separation” is used to constrain the distance between the leading edge of the last laid out frame and the area available for placement. That distance is constrained to be no less than the maximum of:

- the value of the sub-sub-parameter “leading edge” for the last laid out frame;
- the value of the sub-sub-parameter “trailing edge” for the frame to be laid out.

If, within the immediately superior frame, there exist one or more frames laid out in normal order and none laid out in reverse order, then the attribute “separation” is used to constrain the distance between the leading edge of the last laid out frame and the area available for placement. The distance is constrained to be no less than the maximum of:

- the value of the parameter “centre separation” for the last frame laid out in normal order;
- the value of the parameter “centre separation” for the frame to be laid out.

If, within the immediately superior frame, there exist one or more frames laid out in normal order and one or more laid out in reverse order, then for the purpose of calculating the size of the area available for placement, those frames that were laid out in reverse order are temporarily positioned as far as possible in the direction opposite to the layout path, without violating the border allowance or the sub-parameters “offset” specified and “separation” specified for the various frames. In particular, without violating the sub-sub-parameter “centre separation” specified for the first frame laid out in reverse direction and for the last frame laid out in normal order, that is, these frames are separated by a distance constrained to be no less than the maximum of these sub-sub-parameters. Thereafter the area available for placement is determined as described above.

6.5.2.2 Determination of the dimensions for variably positioned frames

The dimensions of a frame within the area available for placement is determined from the attribute “dimensions”.

The dimensions of a frame are said to be tentatively determined when they are determined subject to existing constraints but may be modified as a result of further constraints.

The dimensions of a variably dimensioned frame are tentatively determined whenever a constraint imposed on the position or dimension attributes of a different frame that is not subordinate to this frame has to be evaluated.

The constraints on the dimensions of a variably dimensioned frame are tentatively determined whenever position or dimension attributes or constraints on these of layout objects subordinate to this frame has to be evaluated.

The constraints on the dimensions of a variably dimensioned frame are permanently determined when a following frame receives content within the same immediately superior frame with the same value of the sub-parameter “fill order”. Subsequently, further content may be laid out into the frame but the frame dimensions cannot be changed. Alternatively, the dimensions are permanently determined when there is no more content to be laid out in the frame.

6.5.2.3 Alignment of variably positioned frames

When the dimensions both of a frame and of its immediately superior frame either have been permanently determined or are specified by the “fixed dimension” parameter of the dimension attribute, the frame is aligned according to the sub-parameter “alignment” of the “variable position” parameter within the area available subject to the constraints specified by the sub-sub-parameters “right-hand offset” and “left-hand offset” of the sub-parameter “offset”.
6.6 Allocation of areas for blocks

The content is laid into blocks within frames by the layout process. The blocks are laid out within an available area within a lowest-level frame, which is determined by attributes including “layout path”, “fill order”, “offset”, “separation”, “border” and “concatenation” (see 5.4.2.2, 5.7.3, 5.7.8, 5.7.10, 5.4.1.4 and 5.7.2, respectively).

The content layout process described by each content architecture determines the exact dimensions of blocks within the available area. The structure within a block is also determined by the content architecture.

6.6.1 Determination of the available area

The available area within an immediately superior frame for the creation of a block to lay out the content is determined by the attributes “layout path”, “fill order”, “offset”, “separation”, “concatenation” and any previously laid out blocks within the frame.

In the case that the immediately superior frame is specified to have variable dimensions with a size determined by the content (that is, by the use of the sub-parameters “rule A” “or “rule B”, see 5.4.1.2), then the constraints on the dimensions of the available area are to be transferred to the content layout process during the layout process. In this case, the size of the available area is maximised within the constraints given (which may be derived from the sub-sub-parameters “minimum dimensions”, “maximum dimensions” of the attribute “dimensions” of the frame and by the constraint on the frame dimensions specified by its immediately superior frame or page, see 5.4.1.2).

The attribute “border” which applies to frames and blocks can also affect the available area. If the attribute “border” is specified for the frame involved, or in an applicable default value list for layout objects of object type block, or in a presentation style associated to a basic logical or layout component, then either or both of the frame and block borders have to be taken into account and may reduce the available area.

A frame has a border inside it, and for each of its edges specified by the attribute “border”, the values of the parameters “border line width” and “border freespace width” constrain the available area by deriving a border allowance.

A block has a border on the outside, and for each of the edges specified by the attribute “border”, the values of the parameters “border line width” and “border freespace width” constrain the available area further by deriving a further border allowance.

The border allowance is for each edge the sum of the constraints derived from the attribute “border” applicable to the frame and from the attribute “border” applicable to the block. If for one or more of the edges a border is neither specified for the frame nor for the block, then for these edges the border allowance is zero scaled measurement units.

In all cases the available area is constrained to be both within the border allowance and also within the region defined to satisfy the attribute “offset”.

Thus, for each edge, the greater of the border allowance and the offset for that edge, specified by the relevant one of the attributes “trailing offset”, “leading offset”, “left offset”, and “right offset” constrain the available area within the lowest level frame.

Depending on the value of the attribute “fill order”, two cases need to be taken into account when determining the available area and laying out blocks within the available area. Its permissible values are ‘normal order’ and ‘reverse order’, these are related to the direction specified by the attribute “layout path” of the lowest level frame.

The two cases to be taken into account are as follows.

6.6.1.1 Layout of blocks in normal order

If there is no other block in the immediately superior page or frame, then only the attribute “offset” and the border allowance needs to be considered.

If there exists one or more blocks laid out in normal order but none in reverse order, then the attribute “separation” is used to further constrain the distance between the leading edge of the last laid out block and the available area. That distance is constrained to be greater than the maximum of:

- the value of the parameter “leading edge” for the first logical object with content in the last laid out block;
- the value of the parameter “trailing edge” for the logical object to be laid out.
the sum of the border allowances for the leading edge of the last laid out block and for the trailing edge of the block to be laid out.

In all the other directions the attribute “offset” and the border allowance is used as described in 6.6.1.

The block is positioned as close to the trailing edge of the lowest level frame as is possible under those constraints.

If there exist one or more blocks laid out in reverse order, then the parameter “centre separation” of the attribute “separation” is used to further constrain the distance between the available area and the trailing edge of the first of the blocks laid out in reverse order (which is the closest block laid out in reverse order). That distance is constrained to be greater than the maximum of:

- the value of the parameter “centre separation” for the first logical object with content in the first of the blocks laid out in reverse order;
- the value of the parameter “centre separation” for the logical object to be laid out;
- the sum of the border allowances for the trailing edge of the first of the blocks laid out in reverse order and for the leading edge of the block to be laid out.

The distances of the available area from the immediately superior page or frame, and from the other block(s) laid out in normal order (if any) are further constrained as described above.

The preceding description specifies how the available area is determined when a new block is to be created. This is the case, when concatenation is not in effect. When concatenation is in effect, then the content is continued in an already created block, with or without fixed dimensions, and all constraints are derived from those attributes applicable to the concatenated sequence of components with content in the block.

6.6.1.2 Layout of blocks in reverse order

If there is no other block in the immediately superior page or frame, then only the attribute “offset” and the border allowance needs to be considered.

If there exist one or more blocks laid out in reverse order but none in normal order then, for the purpose of calculating the available area, the blocks already present are temporarily positioned as far as possible in the direction opposite to the layout path, without violating the attribute “offset” or the border allowance specified for the first logical object with content in the first block laid out in reverse order. The attribute “separation” is used to further constrain the distance between the leading edge of the last laid out block and the available area. That distance is constrained to be greater than the maximum of:

- the value of the parameter “leading edge” for the first logical object with content in the last laid out block;
- the value of the parameter “trailing edge” for the logical object to be laid out;
- the sum of the border allowances for the leading edge of the last laid out block and for the trailing edge of the block to be laid out.

In all the other directions the attribute “offset” and the border allowance is used as described in 6.6.1.

The block is positioned as close to the leading edge of the lowest level frame as is possible under those constraints.

If there exist one or more blocks laid out in normal order and none laid out in reverse order, then the attribute “separation” and the border allowance is used to further constrain the distance between the leading edge of the last laid out block and the available area. That distance is constrained to be greater than the maximum of:

- the value of the parameter “centre separation” for the first logical object with content in the last of the blocks laid out in normal order;
- the value of the parameter “centre separation” for the logical object to be laid out;
- the sum of the border allowances for the leading edge of the last of the blocks laid out in normal order and for the trailing edge of the block to be laid out.

In all the other directions the attribute “offset” and the border allowance is used as described in 6.6.1.

The block is positioned as close to the leading edge of the lowest level frame as is possible under those constraints.
If there exist one or more blocks laid out in normal order and one or more blocks laid out in reverse order, then for the purpose of calculating the size of the available area, the blocks laid out in reverse order are temporarily positioned as far as possible in the direction opposite to the layout path. This is done without violating the border allowance, or the parameter “centre separation” of the attribute “separation” specified for the logical object of the first block laid out in reverse order, and for the first logical object with content in the last block laid out in normal order. Thus the blocks are separated by a distance equal to the maximum of those parameters or the combined border allowances. Thereafter the available area is further constrained as described in 6.6.1.

Finally, after the block dimensions have been determined, all blocks laid out in reverse order are positioned as far as possible in the direction of the layout path, without violating the border allowances and the attributes “offset” and “separation” applicable to the various blocks.

The preceding description specifies how the available area is determined when a new block is to be created. This is the case, when concatenation is not in effect. When concatenation is in effect, then the content is continued in an already created block, with or without fixed dimensions, and all constraints are derived from those attributes applicable to the concatenated sequence of components with content in the block.

6.6.1.3 Block alignment orthogonal to layout path
In the direction orthogonal to the layout path, the block position in the available area is defined by the value of the attribute “block alignment” of the first logical object with content in the block. The value may be ‘right aligned’, ‘left aligned’, or ‘centred’ within the available area in the direction orthogonal to the layout path. If the attribute “block alignment” specifies a value of ‘null’ then the reference layout process does not define an alignment in the direction orthogonal to the layout path.

6.7 Alternative representation
If an alternative representation is specified then the layout process does not define the situation when this representation will be used. This is the subject of particular implementations.

If the alternative representation is used then all the layout directives specified for the basic object continue to apply. The character string in the attribute “alternative representation” is treated by the layout process as if the string had been specified in the attribute “content information”; see part 6 of this Standard. The character set is specified by the document profile attribute “alternative representation character sets”.

7. REFERENCE MODEL OF THE DOCUMENT IMAGING PROCESS

This section provides a description of the document imaging process as applicable to documents of the formatted document architecture class or the formatted processable document architecture class (see 2.3.11). Such documents include constituents representing a specific layout structure and may optionally include constituents representing a generic layout structure and/or presentation styles. In the case of the formatted processable document architecture class other constituents are present but these do not affect the imaging process.

The purpose of this section is to aid the understanding of the semantics of the attributes affecting the presentation of the document structure but it does not specify any process that might be carried out in a particular implementation.

The content imaging process, which controls the imaging of content portions within basic layout objects is not described here but in those parts of this Standard relating to particular content architectures.

7.1 Imaging order
The imaging order determines the precedence of layout objects for imaging in the layout object to which they are immediately subordinate. Thus, this order determines how the image of the document is resolved for displaying on the presentation surface.

The imaging order of layout objects that are immediately subordinate to the same layout object is determined by the attribute “imaging order” of that common superior object. The imaging order of layout objects that are not immediately subordinate to a common layout object is determined by the imaging order specified by their lowest common superior layout object.
When the attribute "imaging order" is not specified, the imaging order is determined by the sequential layout order. Thus the imaging order for all layout objects can be uniquely determined.

7.2 Intersection principles

Within a page, frames and blocks may be positioned in such a way that they intersect partially or fully, that is they share common areas. In all cases, subordinates are fully contained within their superiors (see 3.3.1).

A page or frame can be considered as an area which carries within its surface other areas representing its immediately subordinate objects, which may be frames or blocks. Similarly, a block can be considered as an area on which content is placed.

These areas have a texture which is described by two attributes: "colour" and "transparency".

This Standard has the following restrictions:
- "colour" is either 'colourless' or 'white';
- "transparency" is either 'transparent' or 'opaque';
- the texture of pages, frames and blocks is either:
  - 'white', 'opaque';
  - 'colourless', 'opaque';
  - 'colourless', 'transparent'.

For pages, 'colourless', 'opaque' and 'colourless', 'transparent' are equivalent.

'colourless', 'opaque' is intended for hard copy, it allows the colour of page, frame and block areas to be that of the media.

When frames or blocks intersect their intersection is governed by the following rules:
- Their overlay sequence is given by the imaging order, which is the same as the sequential layout order unless an imaging order is explicitly specified. Layout objects later in the imaging order overlay layout objects earlier in the imaging order.
- If an opaque layout object overlays other layout object(s), any content or texture of the underlying object(s), and their subordinates, is not imaged in the area of intersection.
- If a transparent layout object overlays other layout object(s) then the image of this layout object and the layout object(s) which it overlays are imaged superimposed in the area(s) of intersection. Content in the area(s) of intersection is combined.
- For imaging purposes the border and border free space are considered to be an extension of the block area when present. In particular, the border free space has the same texture as the block.

7.3 General rules for positioning pages on presentation surfaces

This clause is concerned with the rules for positioning pages on presentation surfaces.

7.3.1 Nominal page and assured reproduction areas

The page is intended to be positioned and imaged on a unit of the presentation surface. The ideal size of the presentation surface, as assumed by the sender of a document, is a rectangular area called the nominal page.

Thus the page is positioned on a single nominal page. The dimensions of the nominal page are specified by the attribute "medium type".

The nominal page is equal to the ideal paper size (see for example, ISO 216). Hard-copy devices must allow for the possibility of edge losses caused, for example, by gripping losses for paper feeding, paper size tolerances, skew, etc. In order to cater for these edge losses, an assured reproduction area is defined which is the rectangular area that remains on the nominal page after deducting an agreed allowance for edge losses.

7.3.2 Positioning of the page

The position of the page relative to the nominal page is specified by means of an orthogonal co-ordinate system. The origin of this coordinate system is at the top left corner of the nominal page. The horizontal axis corresponds to the top edge and the vertical axis corresponds to the left edge of the nominal page as shown in Figure 14. Horizontal positions are measured positively from the vertical axis to the right and vertical positions are measured positively from the horizontal axis downwards.
If the horizontal dimension is greater than the vertical dimension then the nominal page is in landscape orientation, otherwise it is in portrait orientation (see figure 2–14). The landscape or portrait orientation places no constraint on the orientation of the content on the page. For example, although the nominal page may be specified to be in the portrait orientation, the graphic elements within the page may be rotated so that the nominal page is intended to be viewed in the landscape orientation.

The reference point for the positioning of a page is the top left corner of that page. The position of the page reference point relative to the top left corner of the nominal page is specified by the attribute "page position".

---

Figure 2–14  Nominal page co-ordinate system and orientation

The size of the nominal page and positions on the nominal page are specified as integral multiples of the scaled measurement unit.

If the attribute "page position" is specified, then the position of the page relative to the nominal page is completely determined.

If the attribute "page position" is not specified, the following rules apply to the positioning of the page:

- If each dimension of the page is equal to or less than those of the assured reproduction area, then the page is positioned such that its reference point is coincident with the top left corner of the assured reproduction area;
- If either or both of the page dimensions are larger than those of the assured reproduction area but smaller than those of the nominal page area, then the page should be positioned on the nominal page such that the possibility of information loss is minimised.
- If the page dimensions are equal to those of the nominal page, then the page is positioned such that its reference point is coincident with the top left corner of the nominal page.
- If either or both of the page dimensions are larger than those of the nominal page, then the page should be positioned relative to the nominal page such that the possibility of information loss is minimised.
In all four cases, it is intended that the page is positioned such that its edges are parallel to the edges of the assured reproduction area.

Although the provisions of this part of this Standard would, in principle, permit text to be positioned anywhere on the nominal page, the originator should rely on text reproduction by the recipient only within the assured reproduction area.

7.3.3 **Definition of assured reproduction area**

The assured reproduction areas for ISO A4, North American letter, ISO A3, Japanese legal and Japanese letter paper sizes are defined as shown in figures 2–15, 2–16, 2–17, 2–18 and 2–19, respectively.

The dimensions in these figures are expressed in basic measurement units (BMUs), (see 3.3.4.1).

![Diagram of assured reproduction area](image)

Figure 2–16 – Dimensions and assured reproduction areas for North American Letter page size

Figure 2–17 – Dimensions and assured reproduction areas for ISO A3 page size
Figure 2-18  – Dimensions and assured reproduction areas for Japanese legal page size

Figure 2-19  – Dimensions and assured reproduction areas for Japanese letter page size
7.3.4 Recto/verso pages
The originator can specify that a page is to be imaged on a particular side of a sheet of a hard copy medium.
The nominal page is specified to be imaged on either the 'recto' side, the 'verso' side or on an 'unspecified' side of this medium.
When a document consisting of 'recto' and 'verso' pages is opened, the 'verso' side of a sheet and the 'recto' side of the following sheet are simultaneously visible.

7.3.5 Positioning of pages on soft copy media
For positioning of pages on soft-copy media, the specific characteristics of the soft-copy devices have to be taken into account. Such devices do not require the concept of nominal page or of assured reproduction area.
The physical screen may be organised either to image the complete page or a part of it; such a part is called a window. Mapping complete pages or windows onto the screen is a local operation which can be achieved in different ways; therefore, this is not defined in this Standard.

8. DOCUMENT ARCHITECTURE LEVELS

8.1 Definition of document architecture classes
This clause defines the document architecture classes that may be used in specific applications using this Standard.

Three document architecture classes are distinguished, namely:
- formatted document architecture class;
- processable document architecture class;
- formatted processable document architecture class.

Each class defines:
- the structures that must, or may optionally, be used in documents that pertain to that class;
- the styles permitted in documents that pertain to that class;
- for each structure, the attributes and attribute values that are applicable to the objects in that structure;

For each document architecture class there is no restriction on the object types within the permitted structures that can be used in documents that pertain to that class. However, a document application profile may place restrictions concerning which object types can be used in that application.

For each object type, there is a minimum set of attributes that must be supported by all document application profiles allowing the use of components of that object type. These minimum sets are defined in clause 8.3. The document application profile specifies which other attributes may be used for that application.

Part 1 of this Standard contains a complete definition of the rules for defining document architecture levels in document application profiles.

8.2 The constituents of document architecture classes
The structures that must and that may optionally be present in documents that pertain to the three document classes are defined in Table 2–2.

For each class, some structures must be present and others are optional. A structure that must be present shall be present in any document that pertains to that class. An optional structure may or may not occur in a document of that class. In the case of optional structures, it is the responsibility of each document application profile to define whether that structure may or may not be used in documents conforming to that document application profile.
The structures which are present in any particular document, and whether generic structures are partial or complete is specified by attributes of the document profile.

In addition, processable and formatted processable document architecture classes may permit the use of layout styles. Presentation styles may be permitted in any of the three document architecture classes.

FPDA: Formatted processable document architecture class

8.3 Minimum attribute sets

8.3.1 The minimum sets of attributes applicable to logical component descriptions

The minimum set of attributes applicable to logical objects is:
- Object type
- Object identifier
- Object class
- Subordinates
- Content portions
- Content architecture class or Content type

The minimum set of attributes applicable to logical object classes is:
- Object type
- Object class identifier
- Content portions
- Content architecture class or Content type

In any document, one or other, but not both, of the attributes “content type” and “content architecture class” should be included in the minimum set of attributes applicable to basic logical components.

8.3.2 The minimum sets of attributes applicable to layout component descriptions

The minimum set of attributes applicable to layout objects is:
- Object type
- Object identifier
- Object class
- Content portions
- Content architecture class or Content type
- Position
- Dimensions
The minimum set of attributes applicable to layout object classes is:
- Object type
- Object class identifier
- Content portions
- Content architecture class or Content type
- Position
- Dimensions

In any document, one or other, but not both, of the attributes “content type” and “content architecture class” should be included in the minimum set of attributes applicable to basic layout components.

The attributes “layout path”, “logical source” and “permitted categories” are not to be used in documents conforming to formatted document architecture class.
Appendix A

Notation used to represent document structures

(This Appendix is not part of the Standard)

A.1 Notation for structure diagrams

The notation described below is intended to be an aid for illustrating document structures. In this method, structures are illustrated in the form of structure diagrams, in which each component is represented by a rectangular box. The document root is placed at the top of the diagram and subsequent hierarchical levels in the structure are added by progressing from top to bottom. Lines joining the components represent the division of components into their immediately subordinate components.

In the case of diagrams representing generic structures, one of three mnemonic symbols may be placed below each box to indicate how the immediately subordinate objects are to be generated. This symbol indicates the type of construction expression associated with the object class represented by the box and contained in the attribute “generator for subordinates”. These mnemonic symbols are:

- SEQ: this indicates a sequence construction, that is the immediately subordinate objects are to be generated in order from left to right as written;
- AGG: this indicates an aggregate construction, that is the immediately subordinate objects can be generated in any order;
- CHO: this indicates a choice construction, that is only one can be chosen to form the immediately subordinate object.

In addition, one or two mnemonic symbols can be placed against a branch to indicate how many times the object, or group of objects, at that branch may occur.

These mnemonic symbols are:

- OPT: indicates that an object, or group of objects, is optional; when this symbol is used on its own, it indicates that an object, or group of objects, can occur 0 or 1 time only;
- REP: indicates that an object, or group of objects, may be repeated; when this symbol is used on its own, it indicates that an object, or group of objects, is to occur 1 or more times;
- OPT REP: the use of the symbols together indicates that an object, or group of objects, can occur 0, 1 or more times.

The absence of any of these symbols indicates that the object shall occur once, and once only.

In the case of specific structures, these mnemonic symbols are not used. The diagrams indicate specifically the occurrence of each object in the structure, in the order in which they are specified by the attribute “subordinates”.

A dashed rectangle called a connector can be used to indicate where subtrees are to be added to the structure. For example, subtrees may be illustrated elsewhere in order to simplify the main structure.

In the example below, the subtree shown in figure 2–A.2 is intended to be added in the main structure in figure 2–A.1 at the point indicated by CONNECTOR Z.
Figure 2-A.1  – Example of document structure notation: main structure

Figure 2-A.2  – Example of document structure notation – subtree

The symbol:

is used in a specific structure to indicate a content portion and in a generic structure to indicate generic content portions.
Each box contains a name to identify the component. These names could correspond to the names of components contained within the attribute “user–visible name” and might be used in a user’s application to process a document.

In the case of layout components, the names DOCUMENT LAYOUT ROOT, PAGE–SET, PAGE, FRAME and BLOCK are used to specify the layout object types. The distinction between composite and basic logical objects is not usually indicated on the diagrams since this should be obvious in the majority of cases.

A.2 Notation for expressions
This Sub-clause contains a notation for specifying various types of expression in human readable form.

This notation can be used, for example, in describing example documents or in the specification of a document application profile.

A.2.1 Conventions for production rules
This clause includes notations for:
- construction expressions;
- string expressions;
- numeric expressions;
- object identifier expressions;
- bindings;
- references to binding values.

There are two aspects concerning the definition of this notation. First it is necessary to define the symbols used to denote any particular instance of an expression. Secondly, it is necessary to define a series of production rules for defining all valid instances of the strings of symbols used to denote the expressions.

The production rules are defined using a Backus–Naur–Form (BNF) which makes use of the following symbols:

a) ::= The definition operator, specifies that the string of symbols on the right side is to be substituted for the non–terminal symbol on the left;

b) the alternative operator, used to separate alternatives;

c) <> used to delimit a non–terminal symbol in an expression;

d) -- used to indicate a comment string;

e) { } used to delimit a syntactical unit;

f) [ ] used to delimit an optional syntactical unit, i.e. the syntactical unit may be present or absent;

g) ... a symbol that may follow a syntactical unit, delimited as in c), e) or f) above, to indicate that the syntactical unit may appear one or more times.

The definition of the notation for each type of expression is given in the following sub-clauses. Each definition specifies the allowable terminal symbols that may be used.
A.2.2 **Notation for construction expressions**
The value of the attribute “generator for subordinates” is a construction expression (see 5.3.2.1). This sub-clause defines a human readable notation for construction expressions.
The terminal symbols used are as follows:\n\nSEQUENCE SEQ AGGREGATE AGG CHOICE CHO OPT REP ( )
\nThe allowable formats of construction expressions are defined by the following production rules:

```plaintext
<construction expression> ::= <construction term>  
                      | <sequence construction>  
                      | <aggregate construction>  
                      | <choice construction>  

<sequence construction> ::= SEQUENCE(<term-sequence>)  
                          | SEQ(<term-sequence>)  

<aggregate construction> ::= AGGREGATE(<term-sequence>)  
                           | AGG(<term-sequence>)  

<choice construction> ::= CHOICE(<term-sequence>)  
                        | CHO(<term-sequence>)  

<term sequence> ::= { <construction term> ... }  

<construction term> ::= <required construction factor>  
                      | <optional construction factor>  
                      | <repetitive construction factor>  
                      | <optional repetitive construction factor>  

<required construction factor> ::= <construction factor>  

<optional construction factor> ::= OPT <construction factor>  

<repetitive construction factor> ::= REP <construction factor>  

<optional repetitive construction factor> ::= OPT REP <construction factor>  

<construction factor> ::= <object class identifier>  
                       | <construction expression>  

<object class identifier> ::= any character string from the set of characters:  
                            hyphen –; the capital letters A, B ..., Z; the small letters a, b .... z; digits 0 .... 9  
```

A character string used to represent an object class identifier is a symbol used in this notation only; it is a symbolic representation of an actual object class identifier value (which is according to the format defined in 5.3.1.3).
A.2.3 Notation for string expressions

This sub-clause defines a human readable notation for string expressions, as defined in 5.1.3.1. The terminal symbols used in this notation are as follows:

- MAKE-STRING
- MK-STR
- UPPER-ALPHA
- U-ALPHA
- LOWER-ALPHA
- L-ALPHA
- UPPER-ROMAN
- U-ROM
- LOWER-ROMAN
- L-ROM
- 'H'
- '+'
- '('
- ')'

The allowable formats of string expressions are defined by the following production rules:

<string expression> ::= <atomic string expression> + <string expression>

The symbol '+' indicates concatenation of terms.

<atomic string expression> ::= <string literal>
  | <binding reference>
  | <string function application>

<string literal> ::= "<character string>"
  | '<<hexadecimal string>>'

<string function application> ::= <make string application>
  | <upper alpha application>
  | <lower alpha application>
  | <upper Roman application>
  | <lower Roman application>

<make string application> ::= MAKE-STRING(<numeric expression>)
  | MK-STR(<numeric expression>)

<upper alpha application> ::= UPPER-ALPHA(<numeric expression>)
  | U-ALPHA(<numeric expression>)

<lower alpha application> ::= LOWER-ALPHA(<numeric expression>)
  | L-ALPHA(<numeric expression>)

<upper Roman application> ::= UPPER-ROMAN(<numeric expression>)
  | U-ROM(<numeric expression>)

<lower Roman application> ::= LOWER-ROMAN(<numeric expression>)
  | L-ROM(<numeric expression>)

<binding reference> ::= - - see A.2.7

<numeric expression> ::= - - see A.2.4

When a string literal consists of a character string, the character repertoire that is being used must be indicated. Whenever a character string contains the character " (quotation mark), the convention is to denote this by the characters "" (two consecutive quotation marks).

When a hexadecimal string is used, the allowable characters are: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F.
A.2.4 Notation for numeric expressions

This sub-clause defines a human readable notation for numeric expressions (see 5.1.3.2).

The terminal symbols used are as follows:

INC\textunderscore\text{INCREMENT} \text{\text{INC}} \text{\text{DEC}} \text{\text{ORDINAL}} \text{\text{ORD}} ( )

The allowable formats of numeric expressions are defined by the following production rules:

\[
\text{<numeric expression> ::= <numeric literal>}
\mid \text{<binding reference>}
\mid \text{<numeric function application>}
\]

\[
\text{<numeric literal> ::= - - any negative, zero or positive integer: negative integer values are preceded by hyphen \text{\text{--}}; integer values are represented by a string of digits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9.}
\]

\[
\text{<binding reference> ::= - - see A.2.7}
\]

\[
\text{<numeric function application> ::= <increment function>}
\mid \text{<decrement function>}
\mid \text{<ordinal function>}
\]

\[
\text{<increment function> ::= INC \text{\text{<numeric expression>}}}
\mid \text{INC \text{\text{<numeric expression>}}}
\]

\[
\text{<decrement function> ::= DEC \text{\text{<numeric expression>}}}
\mid \text{DEC \text{\text{<numeric expression>}}}
\]

\[
\text{<ordinal function> ::= ORD \text{\text{<object reference>}}}
\mid \text{ORD \text{\text{<object reference>}}}
\]

\[
\text{<object reference> ::= <object identifier>}
\mid <object identifier expression>
\]

\[
\text{<object identifier> ::= - - any character string from the set of characters: hyphen \text{\text{--}}; the capital letters A, B \ldots Z; the small letters a, b \ldots z; digits 0 \ldots 9}
\]

\[
\text{<object identifier expression> ::= - - see A.2.5}
\]

A character string used to represent an object identifier is a symbol used in this notation only; it is a symbolic representation of an actual object identifier value (which is according to the format defined in 5.3.1.2).
A.2.5 Notation for object identifier expressions
This sub-clause defines a human readable notation for object identifier expressions.
The terminal symbols used in this notation are as follows:
CURRENT-OBJECT CURR-OBJ CURRENT-INSTANCE CURR-INST
SUPERIOR-OBJECT SUP-OBJ PRECEDING-OBJECT PREC-OBJ
DOCUMENT_LAYOUT_ROOT DLAR PAGE_SET PAGE FRAME BLOCK
DOCUMENT_LOGICAL_ROOT DLOR COMPOSITE_LOGICAL_OBJECT
CLO BASIC_LOGICAL_OBJECT BLO ()
The allowable formats of object identifier expressions are defined by the following production rules:

<object identifier expression> ::= <current-object function>
  | <current-instance function>
  | <superior-object function>
  | <preceeding-object function>

<current-object function> ::= CURRENT-OBJECT
  | CURR-OBJ

<current-instance function> ::= CURRENT-INSTANCE(<class or type>,
  <object reference>)
  | CURR-INST(<class-or-type>,
  <object reference>)

<superior-object function> ::= SUPERIOR-OBJECT(<object identifier expression>)
  | SUP-OBJ(<object identifier expression>)

<preceding-object function> ::= PRECEDING-OBJECT(<object identifier expression>)
  | PREC-OBJ(<object identifier expression>)

<class-or-type> ::= <object-class-identifier> | <object-type>

<object class identifier> ::= - - any character string from the set of characters:
  hyphen --; the capital letters A, B .... Z;
  the small letter a, b .... z; digits 0 .... 9

<object type> ::= DOCUMENT_LAYOUT_ROOT | DLAR
  | PAGE_SET
  | PAGE
  | FRAME
  | BLOCK
  | DOCUMENT_LOGICAL_ROOT | DLOR
  | COMPOSITE_LOGICAL_OBJECT | CLO
  | BASIC_LOGICAL_OBJECT | BLO

<object reference> ::= <object identifier>
  | (<object identifier expression>)

<object identifier> ::= - - any character string from the set of characters:
  hyphen --; the capital letters A, B .... Z;
  the small letters a, b .... z; digits 0 .... 9
A character string used to represent an object identifier or an object class identifier is a symbol used in this notation only; it is a symbolic representation of an actual object identifier value or an object class identifier value (which is according to the format defined in 5.3.1.2 and 5.3.1.3, respectively).

A.2.6 Bindings
The attribute “bindings” consists of a set of pairs of parameters, each pair consisting of a binding name and a binding value (see 5.3.5.4).
This sub-clause defines a human readable notation for this pair of parameters.

(binding pair) ::= <binding name>, <binding value>

(binding name) ::= any character string from the minimum subrepertoire of ISO 6937–2, being the value of the binding name parameter.

(binding value) ::= <string expression>
                | <numeric expression>
                | <object reference>

<string expression> ::= - - see A.2.3

<numerical expression> ::= - - see A.2.4

<object reference> ::= <object identifier>
                  | <object identifier expression>

<object identifier> ::= any character string from the set of characters:
                       hyphen –; the capital letters A, B .... Z; the small letters a, b .... z; digits 0 .... 9

<object identifier expression> ::= - - see A.2.5

A character string used to represent an object identifier is a symbol used in this notation only; it is a symbolic representation of an actual object identifier value (which is according to the format defined in 5.3.1.2).

A.2.7 Notation for references to binding values
This sub-clause defines a human readable notation for references to binding values.
The terminal symbols used in this notation are as follows:
BINDING REFERENCE B_REF CURRENT–OBJECT CURR–OBJ SUPERIOR SUP PRECEDING PREC
The allowable formats of object identifier expressions are defined by the following production rules:

```
<binding reference> ::= BINDING_REFERENCE
    (<binding reference expression>)
    (<binding name>)
    | B_REF(<binding reference expression>)
        (<binding name>)

<binding reference expression> ::= <object identifier>
    | <binding selection function>

<binding name> ::= - - any character string from the minimum subrepertoire of ISO 6937–2, being the value of the binding name parameter.

<object identifier> ::= - - any character string from the set of characters: hyphen →; the capital letters A, B .... Z; the small letter a, b .... z; digits 0 .... 9

(binding selection function) ::= <current-object function>
    | <current-instance function>
    | <superior function>
    | <preceding function>

<current-object function> ::= CURRENT–OBJECT
    | CURR–OBJ

<current-instance function> ::= - - see A.2.6

<superior function> ::= SUPERIOR(<object identifier expression>)
                        | SUP(<object identifier expression>)

<preceding function> ::= PRECEDING(<object identifier expression>)
                        PREC(<object identifier expression>)

<object identifier expression> ::= - - see A.2.5
```

A character string used to represent an object identifier is a symbol used in this notation only; it is a symbolic representation of an actual object identifier value (which is according to the format defined in 5.3.1.2).
Appendix B

Examples of Document Structures

(This Appendix is not part of the Standard)

B.1 Introduction

This appendix presents examples of the application of the document architecture specified in this part of this Standard to a single specimen document, namely a typical business letter. Although the prime purpose of these examples is to illustrate the document structures, they also refer to the document layout process described in section 6 and to content layout processes which are described in other parts of this Standard which specify individual content architectures. Some knowledge of these processes, although not essential, would be helpful in reading these examples.

The first two examples (B.4.1, B.4.2) describe how the specimen document can be represented in terms of a specific layout structure and a specific logical structure, respectively. These examples show that the originator may take two distinct views of the same document when it is created, according to the originator's application. That is, they show how the same document may be constructed in formatted form or in processable form.

The third example (B.5) again shows the specimen document in processable form but, in this case, the document includes a generic logical structure and a generic layout structure. These generic structures can be used to provide two examples of document classes. In the first of these examples, the generic logical structure alone can be regarded as the document class from which the specific logical structure, previously described in the second example, can have been generated.

In the second example of document classes, the two generic layout structures may be used together to form the document class. In this case, the generic layout structure may be used to control the layout of the document during the layout process.

The next example (B.6) describes the specific layout structure that would be generated by that layout process. This specific layout structure is not identical to that described in the first example (B.4.1), for reasons that will be explained, but the appearance of the document on a presentation device will be exactly the same as if the document had been laid out according to the specific layout structure described in the first example.

Also note that if the specific layout structure generated by the generic layout structure is interchanged together with the specific logical structure, generic logical structure and generic layout structure described in the third example, then the document is said to be in formatted processable form.

The structures of the document are illustrated by structure diagrams which make use of the notation defined in Appendix A.

B.2 Notation used to specify constituents of a document

A notation described in this clause is used to specify the sets of attribute values which characterize the constituents of the document.

B.2.1 General

In this notation, the specification of each constituent is separated by a horizontal line. In the specification of each constituent the left hand column specifies the attribute names and the right hand column the attribute values.

For example:

```
COMPOSITE LOGICAL
```

**Object Type**

In this example, "object type" is the name of an attribute for which one of the possible values is 'composite logical'.

In this notation, object class descriptions are identified by a name in parentheses as well as a numeric string, rather than a numeric string only, as specified in 5.3.1.3. This makes them easier to relate to the structure diagrams.

Object class descriptions may occur in any order in the tables given in these examples since they are not hierarchically structured. However, they are presented where possible in an order similar to that of the structure diagrams.
Object descriptions are identified by sequences of numbers separated by spaces. That is, their identifiers in these examples have the same form as the value of the attribute "object identifier" as specified in 5.3.1.2.

Object descriptions are written in the tables in these examples in the sequential order defined by the specific structure to which they belong. Subordinate objects are identified by the last element of their identifier.

B.2.2 Generator for subordinates
The notation for construction expressions is as defined in Appendix A.

B.2.3 Content portions
Generic content portion descriptions are identified by a name in parentheses as well as a numeric string, in a manner analogous to that used to identify object class descriptions.

Content portion descriptions within the representation of specific structures are identified by sequences of numbers separated by spaces.

The value of the content information of a content portion is represented in one of two ways:
- as a quoted string, for example, "is a string";
- as a comment string, for example, /*This is another string*/.

Quoted strings are used when the content information can be "reasonably" represented by this syntax.

Comment strings are used when the content information cannot be reasonably represented by the quoted string syntax or when to do so would not significantly improve understanding of the example.

Within quoted strings multiple spaces and new lines have no significance i.e. the presentation of a string is to be interpreted as having no significance. Where control characters are to be considered as significant they are written as:

\x

where x is a single letter or a number followed by a letter.

The letters have the following meanings:
- n - new line;
- s - space;
- t - tabulate.

When one of the above letters is preceded by a number it means the number of control functions as specified by the letter is to be considered as present.

When content portion descriptions are associated with both the specific logical structure and the specific layout structure they are represented as separate constituents with appropriate attribute values for their identifiers.

B.3 Introduction to specimen document
There follows an illustration of an application of the document architecture to a class of documents called "letter". Figures 2–B.1 to 2–B.3 illustrate the specimen document.

The specimen document consists of three pages. The first page contains a logo, a date, the name of the addressee, a statement of the subject and a summary. The second page contains two paragraphs, a figure and the first part of a third paragraph. The last page contains the remaining part of the third paragraph, a fourth paragraph, a formal ending and the signature and name of the letter's originator. The contents of the various paragraphs is shown in a symbolic form.

Figures 2–B.4 to 2–B.6 illustrate the layout structure of this document by outlining various blocks within each page.
To members of ISO/TC97/SC18/WG3

SUBJECT: PROPOSED EXAMPLE TO CLARIFY THE DOCUMENT ARCHITECTURE MODEL

Figure 2-B.1 – Specimen document “letter” (1)
Figure 2-B.4  -  Layout of “letter” showing pages and blocks (1)
B.4 Specific structures

A document can be viewed in two different ways:

- as a layout structure in which the appearance of the document content is of prime concern;
- as a logical structure in which the meaning of the document content is considered, such as its division into chapters, paragraphs.

These two structures are described further below.

B.4.1 Formatted form documents with specific layout structure only

The specimen document has a specific layout structure that can be illustrated by a diagram as in Figure 2–B.7.

The diagram contains the same pages and blocks as Figures 2–B.4 to 2–B.6 but represents these in a hierarchical form. The content is divided into a number of content portions and each of these is allocated to a block. Hence there is a logo block, a date block, a subject block etc. The content portions that belong to each block are found in the bottom row of Figure 2–B.7 (in double lined boxes).

The document contains one paragraph – paragraph C – which is contained in two blocks; each block on a separate page.

Each layout object, i.e. page or block, is characterised by a number of attributes. Table 2–B.1 contains a list of all attributes that have to be specified in this example.

Some attributes that are “defaultable” are not shown in the table. Their values can be derived from the standard default values defined in this part of this Standard (see 5.1.2.4).

B.4.2 Processable form document with specific logical structure only

The logical objects of the specimen document are organised in a hierarchical structure as shown in Figure 2–B.8.

It shows that the document consists of two directly subordinate composite logical objects representing the ‘header’ and ‘body’. The ‘header’ consists of basic logical objects representing the ‘date’, ‘addressee’, ‘subject’, etc. Content portions are assigned to the basic logical objects. There is no basic logical object for the logo because this is assumed to be part of the layout structure only (i.e. either part of the generic layout structure or preprinted on the presentation medium).

The same logical object class can be used in several places (for example, paragraph) but with different content.

Each logical object is characterised by its attributes in the same way as for the layout objects. Tables 2–B.2 and 2–B.3 list all the constituents and the attributes that have to be specified in this example. Defaultable attributes are not listed unless they have been assigned non-default values.

The presentation attributes applicable to the content associated with the basic logical objects are contained in presentation styles which are listed in table 2–B.3. When required, each basic logical object contains an attribute which references an appropriate presentation style.

Presentation attributes specify how the document content is to be presented and imaged on the presentation media. For example, in the case of character content, these attributes specify the line and character spacing intervals and whether or not the content is to be justified.

However, this information is insufficient to lay out the content of the document. Additional information is required concerning the document layout structure, that is information is required relating to the characteristics and internal structure (if any) of the pages on which the document content is to be laid out. In this example, it is assumed that the recipient will provide the required information. The recipient may use this Standard to define such a layout process or the recipient may specify his own rules for deriving the document layout structure.

Hence it should be noted that the recipient is not likely to produce exactly the same layout for the document as illustrated earlier in this appendix. The next example (see 2–B.5) describes how a document can be interchanged in processable form with sufficient information, in the form of generic layout structure, to indicate the layout required.

Also, this example does not make use of layout styles, which contain attributes that, for example, specify the amount of space to be inserted between successive logical objects (using the attribute “separation”) and whether or not certain logical objects should be placed at the start of a new page (using attribute “new layout object”). This does not mean that layout styles cannot be included in documents which are interchanged with logical structure only. However, there is no obligation for the originator to include such information and again it might be necessary for the recipient to supply additional information to obtain an acceptable document layout.

**Table 2-B.3 — Presentation styles for figure 2-B.8**
B.5 Processable form document with generic logical structure and generic layout structure

B.5.1 Introduction
This clause illustrates how the specimen document can be interchanged in processable form with a generic logical structure and a generic layout structure to accompany the specific logical structure.

The generic logical structure facilitates subsequent editing of the document by a recipient. It can be used during the revision process to ensure that the document remains in conformance with a predefined structure, i.e. a document class.

The generic logical structure illustrated in this example (see figure 2-B.9) is one which may have been used to generate the specific logical structure previously shown in figure 2-B.8.

The generic layout structure is used to control the layout of a logically structured document and the imaging of a laid out document when it is applied to the document layout and imaging processes. The generic layout structure specifies what types of layout object can be created during the layout process and in what order they may be created. During the imaging process the generic layout structure provides for attributes that direct the imaging process and provides generic content to be imaged.

The generic layout structure illustrated in this example (see figure 2-B.10) will create an image of the document that is identical to that which would be produced by the specific layout structure described in the first example (see figure 2-B.7).

In order to lay out a logically structured document, each logical object description in that document must be related to a layout object description created by the document layout process using the generic layout structure. This is achieved by means of layout styles, each of which consists of a set of attributes called layout directives. Each logical object description contains an attribute which relates a particular layout style with that object description. The attributes in the layout style then relate the logical object description to the appropriate layout object class description and guide the precise layout of the logical object during the document layout process.

Similarly, the document contains presentation styles, each of which contains a set of attributes called presentation attributes. These guide the layout and imaging of the content associated with the basic logical object descriptions within the document. As in the case of layout styles, a basic logical object description may contain a reference to a certain presentation style and this has the effect of associating a particular set of presentation attributes with that object description.

In this example, the references to layout and presentation styles are not contained within the attributes of the specific logical object descriptions but are contained within the attributes of the object class description corresponding to the specific logical object description. This arrangement can be used, for example, to reduce the number of coded bits required to interchange a document or to facilitate subsequent editing.

B.5.2 Generic logical structure
The generic logical structure, which is shown in figure 2-B.9, specifies the logical object descriptions that may occur in a corresponding specific logical structure and their permitted sequential orders. The sequential order of object descriptions in the specific logical structure is significant since it indicates the order in which the objects are to be processed by the document layout and imaging processes (see 6 and 7).

Referring to figure 2-B.9, the following are the implications for any corresponding specific logical structure. The document logical root description, which has been given the name “letter”, consists of the subordinate composite logical object descriptions given the names “header” and “body”. Both of these object descriptions must occur once only in any corresponding specific logical structure. The mnemonic symbol SEQ placed below the document level indicates that the sequential order of these composite object descriptions in any corresponding specific logical structure must be “header” followed by “body” (i.e. in the order left to right as indicated in the diagram).

The object descriptions subordinate to “header” consist of “date”, “addressee”, “subject”, and “summary”. All of these must occur once in any corresponding specific logical structure and must occur in the order shown in the diagram. The “summary” is a composite logical object description consisting of one or more basic logical object descriptions “paragraph”. Similarly, the composite object description “body” consists of any number and combination of the logical objects “paragraph” and “figure” (as indicated by the mnemonics REF, CHO) followed by object
descriptions “ending” and “signature and name” which must occur once only. There is no logical object “logo” because this is assumed to be part of the generic layout structure.

In this example, both “paragraph” object class descriptions are distinct because different attribute values are associated with them. However, it would be possible, in a different example, for the object descriptions of “summary” and “body” to both refer to the same object class description “paragraph”, which would result in a non-hierarchic generic layout structure.

The object class description “ending” contains a generic content portion description. Any specific logical structure generated from this generic logical structure would contain a logical object description corresponding to “ending” but no content portion description would be associated with this object description. However, since this logical object description would contain a reference to the object class description “ending” in the generic logical structure, the generic content portion description associated with this object class description would be considered to represent the content of the logical object description.

B.5.3 Specific logical structure

The specific logical structure included in this processable form document is identical to that shown in figure 2–B.8 with the single exception that the basic logical object description “ending” will not have a content portion description associated with it. As described in clause B.5.2, this content portion description will be obtained from the generic logical structure.

B.5.4 Generic layout structure

In the example shown in Figure 2–B.10, the generic layout structure called “letter” indicates that a specific layout structure created by the document layout process must consist of a “header” page followed by at least one “body–page” page.

The “header” page contains one generic content portion description for a “logo” and four layout object class descriptions for frames, “date”, “addressee”, “subject” and “summary”.

Each “body–page” page contains one subordinate frame. Note that the diagram indicates that the order of creation of the pages and their subordinate layout objects is significant.

The user–visible names of the layout object class descriptions used in this example have been chosen to indicate the correspondence between object classes in the generic and the specific layout structures.

B.5.5 Object descriptions and object class descriptions

The object class descriptions pertaining to the generic logical structure are given in table 2–B.4. Table 2–B.5 describes the presentation styles and the layout styles associated with the document.

Table 2–B.6 lists the object descriptions for the objects in the specific logical structure. The object descriptions in this table must be interpreted together with the object class descriptions given in table 2–B.4. Note that all content portion descriptions are grouped together since it is assumed that interchange format class A (see part 5 of this Standard) will be used to interchange this particular document.

Table 2–B.7 lists the object class descriptions pertaining to the generic layout structure.

**B.6 Specific layout structure**

Figure 2-B.11 illustrates the specific layout structure generated by the document layout process (see 6) from the specific logical structure, generic logical structure and generic layout structure described in clause 2-B.5.

If a document is in formatted processable form, then this structure would be generated by the originator and interchanged together with the other document structures.

This specific layout structure differs from that in B.4.1 in the following respects:

- the specific layout structure of B.4.1 contains no frames;
- the specific layout structure of B.4.1 contains a content portion description for the object description named “logo”, whereas in figure 2-B.11 this content portion description is omitted because it is specified as part of the generic layout structure.

The object descriptions corresponding to figure 2-B.11 are listed in table 2-B.8. These are to be interpreted in conjunction with the layout object class descriptions listed in table 2-B.7. Also, note that in table 2-B.8, the presentation attributes associated with the content associated with various blocks are specified by means of presentation styles, which are listed in table 2-B.5. In a formatted-processable form document, the content portions in table 2-B.8 replace the ones described in table 2-B.6.

Figures 2-B.12, 2-B.13 and 2-B.14 illustrate the layout structure of the specimen document corresponding to that described in Table 2-B.8, by outlining the frames and blocks within each page.

<td>FPDA 2</td>
<td>complete</td>
<td>all object types</td>
<td>complete</td>
<td>all object types</td>
</tr>
</tbody>
</table>
The abbreviations used in table 2-C.1 have the following meaning:

- none:
  The corresponding structure is not present.

- partial:
  A partial generator set of either logical object class descriptions or layout object class descriptions is present. Such a set may include object class descriptions corresponding to each object and no object class descriptions as special cases.

- complete:
  A complete generator set of either logical object class descriptions or layout object class descriptions is present.

- all object types:
  The columns defining specific logical structures and specific layout structures specify the object types that may be specified in the corresponding structure. “All object types” indicates that any combination of object types is permissible. In the case of specific logical structure, a structure consisting of just document logical root and basic logical objects is a special case. In the case of specific layout structure, a structure containing just document layout root, pages and blocks is a special case.

Further restrictions of the use of these document architecture levels:

a) Pages as basic objects are only permitted in levels FDA0 and FDA1.

b) If a specific logical structure and a generic layout structure are both present in a document then the generic layout structure is always required to be complete, in order that the layout process can be controlled.

c) The layout process can be controlled, so as to meet the specification in section 6, in levels PDA1, PDA3, PDA5 and in the FPDA levels.

d) The editing process can be controlled in levels PDA4, PDA5 and FPDA2.

Appendix D

Examples of particular document architecture features

(This Appendix is not part of the Standard)

D.1 Layout of frames

This Appendix presents examples of the use of the attributes “position”, “dimensions” and “layout path” as applicable to frames.

D.1.1 Conventions

Page, frame and block names are specified in their top left corner indicated by P for pages, F for frames and B for blocks, respectively, indexed by a sequence of digits. Frames or blocks subordinate to pages or other frames, in general, have the same initial sequence of digits as their subordinate object, for example, F11 is immediately subordinate to P1.

Layout path is illustrated by an arrow beside the frame name.

A variable dimension is indicated by double lines.

The value of the attributes are indicated inside the outline of the layout object by short forms:

- HP – horizontal position, the value is either a constant, for the sub-parameter “horizontal position”, indicated by notations of the form “0”, “B”, “C”, “2C”, or is derived from the parameter “variable position”, indicated by notations of the form “alignment = centre” or “left-hand offset = C”,

- VP – vertical position, the value is either a constant, for the sub-parameter “vertical position”, indicated by notations of the form “0”, “A”, “B”, or is derived from the parameter “variable position”, indicated by notations of the form “fill order = reverse order” or “leading edge separation = A”,

- HD – horizontal dimension, the value is either the default value defined in this part of this Standard indicated by the notation “default”, or a constant value for the parameter “horizontal dimension”, indicated by notations of the form “D”, or is derived from a rule, indicated by notations of the form “Rule B”, where the rules are as defined in 5.4.1.2;

- VD – vertical dimension, the value is either the default value defined in this part of this Standard indicated by the notation “default”, or a constant value for the parameter “vertical dimension”, indicated by notations of the form “D” or is derived from a rule, indicated by notations of the form “Rule A” or “Rule B”, where the rules are as defined in 5.4.1.2;

Content of blocks is indicated by annotation of form <...>

The notation adopted for the specification of construction expressions is that specified in Appendix A, sub-clause A.2.2.
D.1.2 Position attribute for a frame in a fixed position

Illustration:

![Diagram showing reference points for a frame in a fixed position]

Figure 2-D.1 – Fixed position frame

D.1.3 Single column text of variable height

Informal description of feature illustrated:

Single column text on a page, positioned after any other material already laid out on the page. The frame is to be generated just sufficiently large as is required to hold the content, with the intention to possibly include other forms of layout on the same page. This may be used to hold a paragraph of text or a figure.

Generator for subordinates:

P : SEQ ( CHO ( F0 ... ) )
F0: none
Figure 2–D.2 — Single column text of variable height
D.1.4  "Wrapping" of text around a left aligned picture

Informal description of feature illustrated:
Single column text on a page, the column being able to include a picture and to allow the "wrapping" of text around a picture. The picture to be placed on the left of the column.

Assumptions:
Picture in geometric graphics content architecture, the dimensions of the picture are specified by the presentation attribute "picture dimensions", specified in that content architecture.
The automatic case is not used, since the dimensions of the picture could then be set so as to use the whole of F1.
The picture specifies layout object class = F11 in order that each picture that occurs causes one instance of F1.
The picture comes earlier in sequential logical order than any of the text to be placed beside it.

Generator for subordinates:
P : SEQ ( CHO ( F0  F1 ) )
F0 : as in D.1.3
F1 : SEQ ( F11  F12 )
F11, F12 : none
Illustration:

Figure 2-D.3  - "Wrapping" of text around a left aligned picture
Variations:
1) If the picture is required to be right aligned:

then the layout path for frame F1 would be reversed (180°). F11 is still the frame with the picture, the positions of F11 and F12 being interchanged, other parameters would be unchanged. The picture is to come earlier in sequential logical order than any of the text to be placed beside it.

2) If the required layout were that the material to be placed beside the picture is to be associated with it and that the description of the figure should be completed in the indented column, before resuming full width lines:

then the rule determining the vertical dimension of F1 would be changed to 'Rule B', other parameters would be unchanged.

3) If the text beside the picture is to be centred vertically in the area beside the picture:
then the vertical position of F12 is specified by the sub-parameter "alignment" with the value 'centred', other parameters would be unchanged.

D.1.5 Picture with text on both sides
Informal description of feature illustrated:
Single column text on a page, with a picture with associated text on both sides of it.

Assumptions:
Picture in geometric graphics content architecture, the dimensions of the picture are specified by the presentation attribute "picture dimensions", specified in that content architecture.
The picture is preceding the associated text in the sequential logical order.
The logical object containing the picture has the layout directive attribute "layout object class" F12 applied to it.
The text with the figure title should be at the bottom of the figure on the left hand side. This is controlled by specifying for the logical object containing that text the layout directive attributes:
- layout object class = F11;
- fill order = reverse order.

The text with other explanatory text associated with the figure is to be centred vertically on the right hand side of the figure. This is controlled by specifying for the logical object containing that text the layout directive attributes:
- layout object class = F13;
- block alignment = centred.

**Generator for subordinates**

P : SEQ ( CHO ( F0  F1 ) )
F0 : as in D.1.3
F1 : SEQ ( F11  F12  F13 )
F11, F12, F13 : none.
Illustration:

Figure 2-D.4  Horizontally centred picture with text on both sides
Variations:
1) The descriptive text on the right associated with the text might be longer or shorter than the figure.

The following modifications to the specification will achieve this effect:
- F1: 'Rule B' rather than 'Rule A';
- F11, F12 and F13 each specify vertical position by sub-parameter "alignment" with value "centred";

The upper of the two pictures illustrates the case when the frame F1 specifies the attribute "border" for all edges, the lower picture has no border.

2) The picture is centred and has all its associated text on the left side, and the main text is running down on the right side.
The only modifications are that frame F13 should have the permitted category including the category for the main text, which will be as specified by F0, its vertical position to be $= 0$.

3) The main text is running down on both sides of the figure, and the figure heading below it. In addition, the heading has a border.

The reading order of the main text is 1, 2, 3, 4, as indicated.

The figure and its heading is represented by a composite logical object with the picture and the figure text as the only two subordinate logical objects, the picture is the first of these. The composite logical object specifies the attribute "layout object class" F12. There is an additional block in frame F12, not illustrated in figure D.4, used to hold the heading of the figure. Frames F11 and F13 both have the same permitted category as required for the main text and their vertical position $= 0$.

D.1.6 Multi-lingual synchronised text
Informal description of feature illustrated:
Three columns of text on a page, each column containing text in different languages. There is required to be horizontal synchronisation at various points, for example, paragraphs, sections.
Assumptions:
Positions and widths of columns are fixed values.
The sets of information to be synchronised are grouped together within the logical structure by a composite logical object, and this object specifies new layout object F1, in order to create a new F1 and thus align the start of the related information.
The related material can cross page boundaries.

*Generator for subordinates:*

P : OPT REP F1
F1: SEQ ( F11  F12  F13 )
F11, F12, F13: none.

*Variation:*

1) If the text of one of the columns is in Japanese, say the third column.

Then the layout path in frame F13 would change to 180° and a number of subordinate frames would be specified, one for each line of Japanese text to be placed in this column. These frames would be balanced, within each of these subordinate frames the layout path is 270°. Therefore the Japanese text would take up as little space in the vertical dimension as possible.
Figure 2-D.5 - Multi-lingual synchronised text
D.1.7 Footnote placement

Informal description of feature illustrated:
Footnote placed at the bottom of the page, full width.
The footnote might be referred to from a multi-column layout of the main text.
If the footnote were referred to from the last line of the main text then a new page may be forced
for both the footnote and the footnote reference.
The footnote may be continued on the next page unless it is specified as being ‘indivisible’.

Generator for subordinates:
P : SEQ ( CHO ( F0  F1 ) )
F1: none
Illustration:

Figure 2-D.6 – Footnote placement
D.1.8 Tabular layout

Informal description of feature illustrated:

Tabular layout, each row having just sufficient lines to contain the content. Table elements may be of any content architecture.

Assumptions:

The column positions and dimensions are fixed by the layout object class descriptions for the table. The generic layout structure does not provide any assistance for column widths and positions to vary. This is indicated by the notation HP = "o", HD = "o".

However, the number of lines required for each row is variable, depending on the content of that row.

Generator for subordinates

P: SEQ ( CHO ( ... Fl ... ) )
F1: SEQ ( F11 ... Fl1 ... )
Fli: SEQ ( Fli1 ... Flij ... )
Figure 2-D.7  – Tabular layout
D.2 Layout of blocks
This clause contains illustrations of the use of the attributes:
- concatenation;
- offset;
- separation;
- layout path;
- fill order;
- block alignment.

D.2.1 Concatenation
Concatenation can be used to lay out an automatically generated chapter number with a chapter heading, see figure 2–D.8. Concatenation can also be used to lay out two or more parts of a paragraph where the parts have been split for reasons of logical structuring, for example because of a footnote reference, see figure 2–D.9.

![Figure 2–D.8 — Concatenation of chapter number and title](image)

![Figure 2–D.9 — Concatenation of parts of a paragraph](image)

D.2.2 Offset
Offset can be used to place a figure or some text at a minimum specified distance from the edges of the frame into which it is laid out.
In figure 2–D.10, the attribute “layout path” is assumed to have its default value of 270° and the attribute “fill order” is assumed to have the value ‘reverse order’. If the attribute “fill order” had the value ‘normal order’ then the figure or text would have been placed towards the top of the page.

Figure 2–D.10  –  Illustration of attribute “offset”

D.2.3  Separation
Separation can be used to place a figure or some text into separate blocks with a minimum specified distance of separation, see figure 2–D.11.

Figure 2–D.11  –  Illustration of attribute “separation”

D.2.4  Layout path
Layout path can be used to control the direction of placement of figures or text into blocks in a frame as they occur in logical order, for example top to bottom or left to right, see figure 2–D.12.
D.2.5 Fill order

Fill order can be used to lay out text or figures from the top or towards the bottom of a frame; alternatively, from the left, right or bottom of a frame and towards the right, left or top of the frame, respectively. The direction used is determined by the layout path, the order of layout is the sequential logical order.

Paragraphs of text are often laid out with ‘normal order’ fill order, footnotes are often laid out with ‘reverse order’ fill order. When a logical sequence of paragraphs and footnotes associated with ‘normal order’ and ‘reverse order’ respectively is laid out, with the default value of layout path (270°), then the paragraphs will be laid out from the top of the page, in their logical sequence in the layout path direction, followed by the footnotes grouped at the bottom of the page, also in their logical sequence in the layout path direction.

Figure 2-D.13 illustrates an example of laying out two paragraphs and two footnotes that occur in the following sequential logical order:

- paragraph 1;
- footnote 1;
- footnote 2;
- paragraph 2.
D.2.6 Block alignment

Block alignment can be used to lay out a block of text or a figure 'left-hand aligned', 'right-hand aligned' or 'centred' in the direction orthogonal to that of the layout path. This could be used, for example, to centre the title of a chapter on the page.

Figure D.14 illustrates the use for aligning figures to the left or right. The figure illustrates that, with the default value of the attribute "layout path" (270°):

- 'left-hand aligned' results in alignment to the right of the immediately superior layout object;
- 'right-hand aligned' results in alignment to the left of the immediately superior layout object.
This figure also illustrates that the alignment is constrained by the specification of the attribute “offset”.

**Figure 2-D.14  Illustration of block alignment**

D.2.7 **Illustration of attributes used in combination**

This sub-clause illustrates the combined use of the attributes “offset”, “separation” and “fill order”.

In this sub-clause the following notation is used:

OT, OLD, OR, OL:

Values of the parameters “trailing offset”, “leading offset”, “right-hand offset” and “left-hand offset”, respectively, of the attribute “offset”, for the block indicated by the subscript.

SL, ST:

Values of the parameters “leading edge”, “trailing edge”, respectively, of the attribute “separation”, for the block indicated by the subscript.

C:

Values of the parameter “centre separation”, of the attribute “separation”, for the block indicated by the subscript.
Figure 2-D.15 — Illustration of the attribute "separation"

Figure 2-D.15 illustrates the combined use of the attributes “offset” and “separation” for two blocks that contain logical objects whose attribute “fill order” has the value ‘normal order’.
Figure 2-D.16 – Illustration of layout of blocks in normal and reverse order

Figure 2-D.16 illustrates the combined use of the attributes “offset”, “separation” and “fill order” and shows blocks that contain the content of logical objects that specify both ‘normal order’ and ‘reverse order’ values of the attribute “fill order”.

Figure 2-D.16 is an example of the layout that would result when blocks are laid out in the order 1, 2, 3, 4, 5 where 1, 3, 4 specify normal fill order and 2, 5 specify reverse fill order.
Figure 2-D.17  –  Illustration of layout of logical objects in normal order

Figure 2-D.17 illustrates the combined use of the attributes “offset”, “separation” and “fill order” and shows blocks that contain the content of logical objects that specify both ‘normal order’ and ‘reverse order’ values of the attribute “fill order”.

Figure 2-D.17 illustrates the determination of the available area during the part of the layout process concerned with positioning of blocks.

In figure 2-D.17, block A has been laid out in ‘normal order’, whereas block B has been laid out in ‘reverse order’. When block C has been laid out, block C will be placed as close to block A as is possible within the indicated available area.
Figure 2-D.18 – Illustration of layout of logical objects in reverse order

Figure 2-D.18 illustrates the determination of the available area during the part of the layout process concerned with positioning of blocks.

In figure 2-D.18, block A has been laid out in ‘normal order’, whereas block B has been laid out in ‘reverse order’. In order to determine the available area for block C, block B has temporarily been moved as far as possible in the direction opposite to layout path. When block C has been laid out, both blocks B and C will be moved as far as possible in the direction of layout path, ensuring that the values of the attributes offset and separation for blocks A, B, C are all complied with, in particular, the value of the attribute “offset” for block C.
D.3 Further constraints on layout
This clause contains illustrations of the use of the attributes:
- layout object class;
- synchronization;
- new layout object;
- same layout object;
- indivisibility;
- balance.

D.3.1 Layout object class
The attribute “layout object class” can also be used to define the appropriate layout areas for particular logical groups of content. The difference from layout category is that the identified logical object is placed in its entirety into a single instance of the layout object. For example, in D.1.4 and figure 2–D.3, the picture is placed into F11 by specifying the layout object class, this ensures that each picture that occurs causes a new instance of F11 and therefore of F1. Also, in D.1.5 and figure 2–D.4, the picture and the associated pieces of text are placed into frames F11, F12 and F13 by specifying layout object class.

D.3.2 Synchronization
The attribute “synchronization” can be used to lay out margin notes beside the associated text, this is illustrated in figure 2–D.19.

![Diagram showing synchronization](image)

Figure 2–D.19 – Illustration of synchronization
D.3.3 New layout object
The attribute “new layout object” can be used to constrain a chapter to start on a new page, see figure 2-D.20.

![Diagram](image1)

Figure 2-D.20 – Illustration of new layout object

D.3.4 Same layout object
The attribute “same layout object” can be used to constrain a chapter heading and the beginning of the first paragraph of the chapter to be laid out together, for example to avoid a page break directly after the chapter heading, see figure 2-D.21.

![Diagram](image2)

Figure 2-D.21 – Illustration of same layout object

D.3.5 Indivisibility
The attribute “indivisibility” can be used to constrain parts of the content such that they are not split during the layout process, for example a figure or a table, see figure 2-D.22. In conjunction with the attribute “same layout object” it could be used to specify that a footnote should be placed entirely on the same page as the footnote reference. The use of “same layout object” by itself would only specify that the text of the footnote is to start on the same page.
D.3.6 Balance

The attribute "balance" can be used to constrain the last page of a chapter that is laid out in 2 column layout to be such that the two columns of text of the chapter on the last page are approximately equal in height, see figure 2-D.23.

A further example was included in D.1.6, variation 1.

D.4 Texture and imaging order attributes

The attributes "transparency" and "colour" together define the texture of pages, frames and blocks. Together with the attribute "imaging order" they describe how to combine the images of the content of overlapping layout objects.
D.4.1 Example 4.1

Figure 2-D.24 illustrates three overlapping blocks '1', '2' and '3', with the imaging order '1', '2', '3', thus:
- block '2' overlays block '1';
- block '3' overlays block '1' and block '2'.

The texture of the blocks is as follows:
- block '1' has the texture 'colourless, opaque';
- block '2' has the texture 'colourless, transparent';
- block '3' has the texture 'colourless, opaque'.

The content of block '3' is all visible, with the background colour that of the media.
The content of block '2' is:
- not visible in the area of intersection with block '3';
- combined with the content of block '1' in their remaining area of intersection;
- visible, with background colour that of the media in the area in which it does not intersect block '1' or block '3'.

The content of block '1' is:
- not visible in the area of intersection with block '3';
- combined with the content of block '2' in their remaining area of intersection;
- visible, with background colour that of the media in the area in which it does not intersect block '2' or block '3'.

![Figure 2-D.24](image_url)
D.4.2 Example 4.2
Figure 2-D.25 shows an example of an overlay order consisting of a page P with two frames F1, F2, and 3 blocks, B1, B2, and B3. The attribute "imaging order" is not specified and thus the imaging order is that of the sequential layout order, which is as represented by the tree structure of figure 2-D.25. The final image is shown in figure 2-D.26. In this example, all blocks have the attribute "layout texture" with the value 'colourless, opaque'.

![Sequential layout order](image)

**Figure 2-D.25** — Sequential layout order

![Final image](image)

**Figure 2-D.26** — Final image
D.4.3  Example 4.3

In this example, multiple levels of frames are considered. The page is defined by the tree structure shown in figure 2–D.27.

![Page Structure Diagram]

**Figure 2–D.27 – Sequential layout order**

The imaging order either specified explicitly or defined by the sequential layout order is:

- page P: imaging order = F1, F2, F3
- frame F1: imaging order = B1, B2
- frame F3: imaging order = F4, F5
- frame F4: imaging order = B4, B5

The values of the attribute “layout texture” are as follows:

- blocks B1, B4 and B6: ‘colourless, transparent’;
- blocks B2, B3 and B5: ‘colourless, opaque’.
To image the proposed page we consider the imaging order given at the page level which makes the frame F1 and its subordinates objects the first to be imaged. Within this frame, B1 is the first block imaged, according to the imaging order below the frame level.

The next block to be imaged is B2, the second and last block that is subordinate to the frame F1. As this block is opaque, the content of B1 is suppressed within the area of intersection.

This is illustrated in figure 2-D.28; to simplify this and subsequent figures, frames are not shown in all cases.

![Image of frames F1, B1, B2](image)

Figure 2-D.28  –  Image within frame F1

The imaging of the blocks subordinate to F1 is now complete. The next step of the imaging process will consider the frame F2, which contains just one block, B3, as specified by the imaging order at the page level. As the value of the attribute “layout texture” is ‘colourless, opaque’, the content of block B2 is suppressed within the area of intersection with block B3 (see figure 2-D.29).

![Image of blocks B1, B2, B3](image)

Figure 2-D.29  –  Imaging of blocks B1, B2, B3
The last branch of the layout structure, the frame F3 must now be imaged. The imaging order specified by this frame indicates that the frame F4 and its subordinate objects are the first to be imaged. Block B4 which has “layout texture” ‘colourless, transparent’ has its content added to the current composite image as illustrated in figure 2-D.30. This block does not intersect with other blocks that have been previously imaged.

![Diagram](image)

**Figure 2-D.30 – Image of block B4 added**

The block B5 in frame F4 is now imaged. This block has “layout texture” ‘colourless, opaque’ and the content of B2 and B4 are suppressed in their area of intersection with B5 (see figure 2-D.31).

![Diagram](image)

**Figure 2-D.31 – Image of block B5 added**
The final block of the page which must be the last imaged as defined by the imaging order is B6. As this block has "layout texture" 'colourless, transparent', its content is combined with the intersecting blocks B1, B2, B3, B4, and B5. This completes the imaging process and the finished page is shown in figure 2-D.32.

![Figure 2-D.32 – Final image](image-url)

**D.4.4 Example 4.4, example of an application**

An example of an application of this feature could be to a map with an overlaid transparent grid, both the map and the grid are overlaid with an opaque key at a fixed position. The map could have a generic description in which the key and the grid could be generic content portions while the particular map would be specific content.

**D.5 Bindings, content generator**

The attribute "bindings" together with the attribute "content generator" can be used to automatically create numbering schemes for layout and logical objects, for example pages, sections, chapters, footnotes, or other application specific logical structure, for example, "part numbers".
Figure D.33 illustrates the automatic creation of chapter numbers.
In this illustration, each chapter has a subordinate logical object "Nr" which represents the chapter number.
Each of these logical objects specifies an attribute "bindings", which specifies a binding name, binding value pair of parameters. The binding name is also "Nr" (by coincidence). The binding value is defined by an expression which defines the value in terms of the previous chapter number, incremented by one.
All expressions in this example are specified using the notation specified in Appendix A.
The expression specified by the binding value is:

```
INCREMENT
  ( BINDING_REFERENCE
    ( PRECEDING ( CURRENT_OBJECT ) )
    ( Nr))
```

The evaluation of the binding-reference will search backwards in sequential logical order through the specific logical structure until a binding with the binding name "Nr" is located. The value of this binding will then be taken and incremented by one to form the value of the current binding.
In order to generate the chapter number the basic logical object "Nr" also specifies a content generator. This content generator will use the string expression:

```
MAKE_STRING
  ( BINDING_REFERENCE
    ( CURRENT_OBJECT)
    ( Nr))
```

This expression returns a string representation of the chapter number, which will be incorporated as the "content information" in a content portion of the specific layout structure for the document.
The chapter number binding values can be initialised by specifying a binding value at the document root level, to set the initial value of the bindings with binding name Nr to integer value zero.
This is set to zero such that the first chapter number will be one. The binding name, binding value pair specified at the document logical root is (0, Nr), where 0 is a numeric literal and Nr is the binding name.
Layout and presentation characteristics of the chapter number may be specified by referencing layout or presentation styles from the basic logical object.
Figure 2-D.33  – Use of bindings and content generator for numbering chapters
Appendix E

The defaulting mechanism

(This Appendix is not part of the Standard)

This appendix summarises some aspects of the defaulting mechanism.

E.1 The defaulting mechanism as applicable to each defaultable attribute

Table 2–E.1 summarises the steps of the defaulting mechanism described in 5.1.2.4 as these apply to the various attributes.

Table 2–E.1  — Applicable steps for defaulting of attributes

The table above shows the steps from 5.1.2.4 for each attribute.
E.2 Determination of content portions and their associated attributes

E.2.1 Determination of content associated with basic logical objects

During the layout process the content associated to a basic logical object is determined according to the first of the following rules which is applicable:

1) One or more content portions are specified for the basic logical object and in at least one of them the attribute “content information” is specified.

In this case, the content associated to the basic logical object is formed by the concatenation of the strings specified for the attribute “content information” for each content portion, in the sequential order of the content portions.

The content portion attributes are derived from the corresponding content portions.

2) One or more content portions are specified for the basic logical object, none of the content portions specifies the attribute “content information”. The attribute “content generator” is specified for the basic logical object.

In this case, the content associated to the basic logical object is formed by evaluation of the attribute “content generator”.

The content portion attributes are derived from the first content portion in sequential order.

3) One or more content portions are specified for the basic logical object, none of the content portions specifies the attribute “content information”. The attribute “content generator” is not specified for the basic logical object.

In this case, the content associated to the basic logical object is a “null” string.

The content portion attributes do not apply.

4) No content portions are specified for the basic logical object. The attribute “content generator” is specified for the basic logical object.

In this case, the content associated to the basic logical object is formed by evaluation of the attribute “content generator”.

The content portion attributes are derived using the rules for determining values of attributes of content portions (see 5.1.2.5).

5-8) If the basic logical object description refers to an object class description which either specifies content portions or specifies the attribute “content generator”, then apply the rules defined in steps 1) – 4), using the content portions and/or attribute “content generator” specified by the object class description, as steps 5) – 8), respectively.

9-12) If the basic logical object description refers to an object class description which refers to an object class description in the resource-document which either specifies content portions or specifies the attribute “content generator”, then apply the rules defined in steps 1) – 4), using the content portions and/or attribute “content generator” specified by the object class description in the resource-document, as steps 9) – 12), respectively.

13) If no content is determined by the preceding steps 1) – 12), then the content associated with the basic logical object is a “null” string.

The content portion attributes do not apply.
E.2.2 Determination of content associated with layout objects

This is performed partly during the layout process and partly during the imaging process.

E.2.2.1 Determination during the layout process

During the layout process the content to be associated to a basic layout object is determined according to the first of the following rules which is applicable:

1) One or more content portions are specified for the object class description used to create the basic layout object, in at least one of these the attribute “content information” is specified.

In this case, the final determination of the content can be deferred until the imaging process (see E.2.2.2).

2) One or more content portions are specified for the object class description used to create the basic layout object, none of the content portions specifies the attribute “content information”. The attribute “content generator” is specified for the object class description.

In this case, the content associated to the basic layout object is formed by evaluation of the attribute “content generator”.

The content portion attributes are derived from the first content portion in sequential order.

3) One or more content portions are specified for the object class description used to create the basic layout object, none of the content portions specifies the attribute “content information”. The attribute “content generator” is not specified for the object class description.

In this case, the content associated to the basic layout object is a “null” string.

The content portion attributes do not apply.

4) No content portions are specified for the object class description used to create the basic layout object. The attribute “content generator” is specified for the object class description.

In this case, the content associated to the basic layout object is formed by evaluation of the attribute “content generator”.

The content portion attributes are derived using the rules for determining values of attributes of content portions (see 5.1.2.5).

5–8) If the object class description used to create the basic layout object refers to an object class description in the resource–document which either specifies content portions or specifies the attribute “content generator”, then apply the rules defined in steps 1) – 4), using the content portions and/or attribute “content generator” specified by the object class description in the resource–document, as steps 5) – 8), respectively.

9) If no content is determined by the preceding steps 1) – 8), then the content associated with the basic layout object is a “null” string.

The content portion attributes do not apply.

During the layout process the content associated with a frame is determined according to the first of the following rules which is applicable:

1) If the attribute “logical source” is specified in the object class description of object type frame then the corresponding logical objects are created and the associated content is evaluated as described in E.2.1 and laid out within a frame object of this class.

2) If item 1) does not apply but the attribute “logical source” is specified in an object class description in a resource–document referenced by an object class description of object type frame then the corresponding logical objects are created and the associated content is evaluated as described in E.2.1, and laid out within a frame object of this class.

3) If items 1) and 2) do not apply, layout objects derived from an object class description of object type frame may be used by the layout process to layout content associated with the specific logical structure (and evaluated as described in E.2.1).
E.2.2.2 Determination during the imaging process

During the imaging process the content associated to a basic layout object is determined according to the first of the following rules which is applicable:

1) One or more content portions are specified for the basic layout object.  
   In this case, the content associated to the basic layout object is formed by the concatenation of the strings specified for the attribute "content information" for each content portion, in the sequential order of the content portions.  
   The content portion attributes are derived from the corresponding content portions.

2) The basic layout object description refers to an object class description which specifies content portions.  
   In this case, the content associated to the basic layout object is formed by the concatenation of the strings specified for the attribute "content information" for each of the content portions associated with the object class description, in the sequential order of these content portions.  
   The content portion attributes are derived from the corresponding content portions.

3) The basic layout object description refers to an object class description which refers to an object class description in the resource–document which specifies content portions.  
   In this case, the content associated to the basic layout object is formed by the concatenation of the strings specified for the attribute "content information" for each of the content portions associated with the object class description in the resource–document, in the sequential order of these content portions.  
   The content portion attributes are derived from the corresponding content portions.

4) If no content is determined by the preceding steps 1) – 3), then the content associated with the basic layout object is a "null" string.
Appendix F

Attribute summary tables

(This Appendix is not part of the Standard)

This appendix contains summary material describing all attributes defined in the document architecture.

These attributes are summarised in tables 2–F.1 and 2–F.2.

Table 2–F.1 lists the attributes, references the definition of the attribute and also references other locations containing specification material pertaining to the attribute.

Table 2–F.2 lists which attributes can be specified for each of the different types of constituent, and whether the attribute is classified as mandatory, non-mandatory or defaulable. (This table is presented in six parts.)

Table 2–F.3 lists which layout directive attributes can be applied for each of the types of layout component.

Standard ECMA–101 – Open Document Architecture (ODA) and Interchange Format

Part 4 – Document Profile

This second edition of Standard ECMA–101 has been prepared by ECMA/TC29 to align ECMA–101 with the current ISO/CCITT publications.

At present this standard consists of seven parts:
- Part 1. Introduction and General Principles;
- Part 2. Document Structures;
- Part 4, Document Profile;
- Part 5, Open Document Interchange Format (ODIF);
- Part 6, Character Content Architectures;
- Part 7, Raster Graphics Content Architectures;
- Part 8, Geometric Graphics Content Architectures.

At present, there is no part 3.

Further parts may be added to this ECMA Standard.

This part 4 contains three Appendices:
- Appendix A: Format of Personal names;
- Appendix B: Minimum Set of Document Profile Attributes to be supported by Document Application Profiles;
- Appendix C: Example.
1. **SCOPE**

The purpose of this Standard ECMA–101 is to facilitate the interchange of documents.

In the context of this Standard, documents are considered to be items such as memoranda, letters, invoices, forms and reports, which may include pictures and tabular material. The content elements used within the documents may include graphic characters, geometric graphics elements and raster graphics elements, all potentially within one document.

**NOTE 4-1**

This Standard is designed to allow for extensions, including typographical features, colour, spreadsheets and additional types of content such as sound.

This Standard applies to the interchange of documents by means of data communications or the exchange of storage media.

It provides for the interchange of documents for either or both of the following purposes:

- to allow presentation as intended by the originator;
- to allow processing such as editing and reformatting.

The composition of a document in interchange can take several forms:

- formatted form, allowing presentation of the document;
- processable form, allowing processing of the document;
- formatted processable form, allowing both presentation and processing.

This Standard also provides for the interchange of ODA information structures used for the processing of interchanged documents.

Furthermore, this Standard allows for the interchange of documents containing one or more different types of content such as character text, images, graphics and sound.

This part of ECMA–101

- defines the purpose of the document profile;
- specifies the attributes which constitute the document profile.

2. **REFERENCES**

- *Part 1 – Introduction and general principles;*
- *Part 2 – Document structures;*
- *Part 5 – Open document interchange format (ODIF);*
- *Part 6 – Character content architectures;*
- *Part 7 – Raster graphics content architectures;*
- *Part 8 – Geometric graphics content architectures.*

ISO 8601 : *Data elements and interchange formats – Information interchange – Representation of dates and times.*

3. **DEFINITIONS**
   For the purpose of this part of this Standard, the definitions given in Part 1 apply.

4. **PURPOSE OF THE DOCUMENT PROFILE**
   The document profile provides information by means of attributes which pertain to the document as a whole. It includes information for processing the document (e.g. reformatting, editing, filing/retrieval).
   A document profile may be interchanged or stored without the body of the document. In such a case, the attribute “local file references” may be used to indicate the location of the document.
   The document profile contains information for use by human beings and for machine processing.

5. **CONTENT OF THE DOCUMENT PROFILE**
   This clause is a list of attributes that may occur within the document profile.

5.1 **Values of document profile attributes**
   The value of each attribute is either user-specified or specified in this part of this Standard.
   Where attribute values consist of character strings, the document profile character set is used. This set consists of SPACE, CARRIAGE RETURN, LINE FEED and a set of graphic characters. In the absence of the attribute “profile character sets,” this set of graphic characters consists of the 73 graphic characters of the minimum subrepertoire of ISO 6937–2.

5.2 **Presence of document constituents**
   The attributes defined in this section indicate the presence of document constituents associated with the document body, whether or not interchanged with the document profile.

5.2.1 **Generic layout structure**
   This attribute is used if and only if the document contains any layout object class descriptions.
   The value of this attribute (if specified) is one of ‘factor set’, ‘partial generator set’ or ‘complete generator set’.

5.2.2 **Specific layout structure**
   This attribute is used if and only if the document contains any layout object descriptions.
   The value of this attribute (if specified) is ‘present’.

5.2.3 **Generic logical structure**
   This attribute is used if and only if the document contains any logical object class descriptions.
   The value of this attribute (if specified) is one of ‘factor set’, ‘partial generator set’ or ‘complete generator set’.

5.2.4 **Specific logical structure**
   This attribute is used if and only if the document contains any logical object descriptions.
   The value of this attribute (if specified) is ‘present’.

5.2.5 **Layout styles**
   This attribute is used if and only if the document contains any layout styles.
   The value of this attribute (if specified) is ‘present’.

5.2.6 **Presentation styles**
   This attribute is used if and only if the document contains any presentation styles.
   The value of this attribute (if specified) is ‘present’.

5.2.7 **External–document class**
   This attribute is used if and only if the document refers to one or more of the generic layout structure, generic logical structure, layout styles and presentation styles defined in an external–document class description. This attribute has no effect if any generic layout or generic logical structure is present in the document.
The value of this attribute is either an ASN.1 object identifier or a string of characters from the document profile character set.

This value is equal to the value of the document profile attribute “document reference” of the document referred to.

Constraints on the permitted external-document classes may be specified by the document application profile.

5.2.8 Resource-document

This attribute is used if and only if the document refers to a resource-document.

The value of this attribute is either an ASN.1 object identifier or a string of characters from the document profile character set.

This value is equal to the value of the document profile attribute “document reference” of the document referred to.

5.2.9 Resources

This attribute provides a mapping between names and identifiers of object class descriptions within the body of the document in order that the document may be used as a resource-document.

The value of this attribute consists of one or more pairs, each pair comprising a character string, representing the name, and an object class identifier.

The characters used in resource names are limited to those of the minimum subrepertoire of ISO 6937–2.

5.3 Document characteristics

5.3.1 Document application profile

This attribute specifies the document application profile that pertains to the document.

The value of this attribute is either an ASN.1 object identifier or an integer.

The integer value is used only to identify the document application profile for Group 4 Facsimile, Class 1, defined in CCITT Recommendation T.503. In this case, the value of the integer is 2.

The absence of this attribute indicates that all constituents, attributes and attribute values defined in parts 1, 2, 4, 5, 6, 7 and 8 of this Standard are permitted to be used, that all features are basic, and that the default values are those defined in this Standard.

5.3.2 Document application profile defaults

This attribute specifies the default attribute values, specified in the document application profile, which are different from the values specified in this Standard.

The document architecture attributes for which a document application profile may define non-standard values are:

- content architecture class;
- content type;
- dimensions, only in the case that this attribute applies to a component of object type page;
- transparency;
- colour;
- border;
- layout path;
- page position;
- medium type;
- block alignment;
- type of coding.

Specifications of the presentation attributes and coding attributes for which a document application profile may define non-standard default values are given in parts 6, 7 and 8 of this Standard.
The value of this attribute is a list of default values for any of the defaultable attributes (document architecture attributes as well as content architecture attributes) for which the document application profile defines a default value different from the default value defined in this Standard.

5.3.3 Document architecture class
This attribute specifies the document architecture class used in the document.
The value of this attribute is 'formatted', 'processable' or 'formatted processable', representing one of the document architecture classes defined in part 2 of this Standard.

5.3.4 Content architecture classes
This attribute specifies the content architecture classes used in the document.
The value of this attribute consists of one or more ASN.1 object identifiers referring to content architecture classes defined in this Standard or in other standards.
Constraints on the permitted content architecture classes may be specified by the document application profile. The value of each object identifier must designate a content architecture class defined in accordance with the rules specified in part 2 of this Standard.

NOTE 4-2
If no document application profile is specified, this attribute can only take values of identifiers of content architecture classes specified in parts 6, 7 and 8 of this Standard (see 5.3.1).

5.3.5 Interchange format class
This attribute specifies the interchange format class used to represent the document.
The value of this attribute is 'A' or 'B', representing one of the interchange format classes defined in part 5 of this Standard.

5.3.6 ODA version
This attribute identifies the Document Architecture Standard or Recommendation, and its version, to which the document conforms.
The value of this attribute consists of two parameters. The value of the first parameter is a string of characters from the document profile character set which identifies the Document Architecture Standard or Recommendation. The value of the second parameter is a complete representation of a calendar date (as defined in ISO 8601), which indicates that the document conforms to the version and addenda current on this date.

5.3.7 Non–basic document characteristics

5.3.7.1 Profile character sets
This attribute specifies the graphic character set(s), other than the character set specified in 5.1, used in those document profile attributes that consist of character strings.
The value of this attribute consists of the escape sequence(s) used to announce and to designate the set(s) in accordance with ISO 2022 and the register of ISO 2375.

5.3.7.2 Comments character sets
This attribute specifies the graphic character set(s), other than the default character set specified in part 2 of this Standard, used in the document architecture attributes "user-readable comments" and "user-visible name".
The value of this attribute consists of the escape sequence(s) used to announce and to designate the set(s) in accordance with ISO 2022 and the register of ISO 2375.

5.3.7.3 Alternative representation character sets
This attribute specifies the graphic character set(s), other than the default character set specified in part 2 of this Standard, used in the document architecture attribute "alternative graphic representation".
The value of this attribute consists of the escape sequence(s) used to announce and to designate the set(s) in accordance with ISO 2022 and the register of ISO 2375.
5.3.7.4 Document constituent attributes

5.3.7.4.1 Page dimensions
This attribute specifies the non–basic values of the attribute “dimensions” of layout objects of type ‘page’ used in the document.
The value of this attribute consists of one or more pairs of page dimensions. A pair of page dimensions shall be included in this attribute when the horizontal component and/or the vertical component of the page dimensions exceed the corresponding components of the basic page dimensions specified by the document application profile.
Each pair of page dimensions is represented by a pair of positive integers specifying the horizontal and vertical components of the page dimensions in scaled measurement units.

5.3.7.4.2 Medium types
This attribute specifies the non–basic values of the attribute “medium type” used in the document.
The value of this attribute consists of one or more groups of parameter values. Each group consists of the parameter “nominal page size” and/or the parameter “side of sheet”, and details one non–basic medium type used in the document. The meaning and format of each parameter is defined in part 2 of this Standard.

5.3.7.4.3 Layout paths
This attribute specifies the non–basic values of the attribute “layout path” used in the document.
The value of this attribute consists of one or more values of the attribute “layout path”, as defined in part 2 of this Standard.

5.3.7.4.4 Protections
This attribute specifies the non–basic values of the attribute “protection” used in the document. The value of this attribute consists of one or more values of the attribute “protection”, as defined in part 2 of this Standard.

5.3.7.4.5 Block alignments
This attribute specifies the non–basic values of the attribute “block alignment” used in the document.
The value of this attribute consists of one or more values of the attribute “block alignment”, as defined in part 2 of this Standard.

5.3.7.4.6 Fill orders
This attribute specifies the non–basic values of the attribute “fill order” used in the document.
The value of this attribute consists of one or more values of the attribute “fill order”, as defined in part 2 of this Standard.

5.3.7.4.7 Transparencies
This attribute specifies the non–basic values of the attribute “transparency” used in the document.
The value of this attribute consists of one or more values of the attribute “transparency”, as defined in part 2 of this Standard.

5.3.7.4.8 Colours
This attribute specifies the non–basic values of the attribute “colour” used in the document.
The value of this attribute consists of one or more values of the attribute “colour”, as defined in part 2 of this Standard.
5.3.7.4.9 **Borders**

This attribute specifies the non-basic values of the attribute “border” used in the document.

The value of this attribute consists of one or more values of the attribute “border”, as defined in part 2 of this Standard.

5.3.7.4.10 **Page positions**

This attribute specifies the non-basic values of the attribute “page position” used in the document.

The value of this attribute consists of one or more values of the attribute “page position”, as defined in part 2 of this Standard.

5.3.7.4.11 **Types of coding**

This attribute specifies the non-basic values of the attribute “type of coding” used in the document.

The value of this attribute consists of one or more values of the attribute “type of coding”, as defined in part 2 of this Standard.

5.3.7.5 **Coding attributes**

This attribute consists of one or more sets of coding attribute values used in the document. Each set pertains to a single content type and consists of coding attribute values that are specified as non-basic by the document application profile.

The names of the sets of coding attribute values are:
- character coding attributes;
- raster–graphics coding attributes;
- geometric–graphics coding attributes.

5.3.7.6 **Presentation features**

This attribute consists of one or more sets of presentation features used in the document. Each set pertains to a single content type and consists of presentation features that are specified as non-basic by the document application profile.

Presentation features consist of presentation attribute values, control function parameter values, sets of content elements and their parameter values.

The names of the sets of presentation features are:
- character presentation features;
- raster–graphics presentation features;
- geometric–graphics presentation features.

5.3.8 **Non-basic structure characteristics**

5.3.8.1 **Number of objects per page**

This attribute specifies the maximum number of specific layout objects per page used in the document. This attribute is only specified if the maximum number of objects per page exceeds the value specified by the document application profile.

5.3.9 **Additional document characteristics**

5.3.9.1 **Unit scaling**

This attribute specifies a scaling factor that is to be applied to all attributes and numeric control function parameters that specify absolute or relative positions and dimensions.

The value of this attribute is a pair of integers m and n which indicate that these positions and dimensions are to be interpreted as being expressed in units equal to m/n BMU. The name of this unit is Scaled Measurement Unit (SMU).
In the absence of this attribute, the Scaled Measurement Unit is equal to 1 BMU.

5.3.9.2 **Fonts list**
This attribute specifies the character font(s) used in the document.
The value of this attribute consists of one or more pairs, each pair comprising an integer, representing the font identifier, and a font reference. A font reference consists of a subset of the font attributes defined in ISO 9541-5. Appropriate subsets are defined in ISO 9541-6.
A font is referred to from within the document by means of the associated integer font identifier.

*NOTE 4-3*
The font attributes defined in ISO 9541-5 include both a structured font name and a set of character attributes.

5.4 **Document management attributes**

5.4.1 **Document description**

5.4.1.1 **Title**
This attribute gives the name of the document as specified by the author.
The value of this attribute consists of a string of characters from the document profile character set.

5.4.1.2 **Subject**
This attribute contains information to indicate the subject of the document.
The value of this attribute consists of a string of characters from the document profile character set.

5.4.1.3 **Document reference**
This attribute identifies the document. The attribute’s value is used to refer to the document from other documents (see 5.2.7, 5.2.8 and 5.4.5).
The value of this attribute is either an ASN.1 object identifier or a string of characters from the document profile character set.

5.4.1.4 **Document type**
This attribute specifies the type of document, e.g. memorandum, letter, report, resource. This attribute specifies only an informal name; it does not specify a relation to a particular document class description.
The value of this attribute consists of a string of characters from the document profile character set.

5.4.1.5 **Abstract**
This attribute contains information to summarize the document.
The value of this attribute consists of a string of characters from the document profile character set.

5.4.1.6 **Keywords**
This attribute specifies one or more character strings that permit logical associations to be made about the content of the document.
The value of this attribute consists of string(s) of characters from the document profile character set.

5.4.2 **Dates and times**

5.4.2.1 **Document date and time**
This attribute specifies the date and, optionally, the time of day that the originator associates with the document.
The value of this attribute consists of a date character string and, optionally, a time of day character string, in accordance with ISO 8601.

5.4.2.2 Creation date and time
This attribute specifies the date and, optionally, the time of day when the document was created.
The value of this attribute consists of a date character string and, optionally, a time of day character string, in accordance with ISO 8601.

5.4.2.3 Local filing date and time
This attribute specifies the date and, optionally, the time of day when the document was filed. When more than one entry occurs, the last entry indicates the most recent local filing date and time.
The value of this attribute consists of a date character string and, optionally, a time of day character string, in accordance with ISO 8601.

5.4.2.4 Expiry date and time
This attribute specifies the date and, optionally, the time of day after which the document is considered to be invalid.
The value of this attribute consists of a date character string and, optionally, a time of day character string, in accordance with ISO 8601.

5.4.2.5 Start date and time
This attribute specifies the date and, optionally, the time of day after which the document is considered to be valid.
The value of this attribute consists of a date character string and, optionally, a time of day character string, in accordance with ISO 8601.

5.4.2.6 Purge date and time
This attribute specifies the date and, optionally, the time of day after which the document can be purged from wherever it is stored.
The value of this attribute consists of a date character string and, optionally, a time of day character string, in accordance with ISO 8601.

5.4.2.7 Release date and time
This attribute specifies the date and, optionally, the time of day after which the document can be released from any restrictions specified in the attribute “security classification”.
The value of this attribute consists of a date character string and, optionally, a time of day character string, in accordance with ISO 8601.

5.4.2.8 Revision history
This attribute specifies the history of the document, indicating when, where and by whom the document was created and revised.
The value of this attribute consists of a sequence of groups of parameters. Each group forms an entry in the history. The first group in the sequence provides information on the creation of the document. The last group in the sequence provides information on the current version of the document. Each group consists of the following optional parameters:
a) revision date and time;
b) version number;
c) reviser(s);
d) version reference;
e) user comments;
where
- “revision date and time” indicates the date and, optionally, the time of day on which a revision occurred; the format is in accordance with ISO 8601;
“version number” indicates the version number of the document resulting from the revision; the format is a string of characters from the document profile character set;

“reviser(s)” identifies the person(s) who carried out a revision; the identification may include the specification of the name of one or more individuals, information to identify their position within an organization, and the name of the organization; the format consists of the following three optional sub-parameters:

1) name(s);
2) position;
3) organization;

where

“name(s)” has the format of one or more personal names, according to the format specified in Appendix A;

“position” is a string of characters from the document profile character set;

“organization” is a string of characters from the document profile character set;

“version reference” is either an ASN.1 object identifier or a string of characters from the document profile character set; the value of this parameter is equal to the value of the document profile attribute “document reference” of the document referred to;

“user comments” describes the revisions made; the value of this parameter is a string of characters from the document profile character set.

5.4.3 Originators

5.4.3.1 Organizations
This attribute identifies the originating organization(s) associated with the document.
The value of this attribute consists of string(s) of characters from the document profile character set.

5.4.3.2 Preparers
This attribute identifies the name(s) of the person(s) and/or organization(s) responsible for the preparation of the document.
The value of this attribute consists of one or more entries. Each entry has two optional parameters:

- “personal name of preparer”, according to the format specified in Appendix A;
- “preparer’s organization”, a string of characters from the document profile character set, which indicates information about the organization responsible for preparing the document, e.g. name, address, telephone number.

5.4.3.3 Owners
This attribute identifies the current administrator(s) of the document.
The value of this attribute consists of one or more entries. Each entry has two optional parameters:

- “personal name of owner”, according to the format specified in Appendix A;
- ”owner’s organisation”, a string of characters from the document profile character set, which indicates information about the organization which owns the document, e.g. name, address, telephone number.

5.4.3.4 Authors
This attribute identifies the author(s) of the document.
The value of this attribute consists of one or more entries. Each entry has two optional parameters:

- “personal name of author”, according to the format specified in Appendix A;
- “author’s organization”, a string of characters from the document profile character set, which indicates information about the organization responsible for the authorship of the document, e.g. name, address, telephone number.
5.4.4 Other user information

5.4.4.1 Copyright
The value of this attribute consists of one or more entries. Each entry has two optional parameters:
- "copyright information", identifying the name(s) of the legal party (parties) in whom the copyright of the document is vested; the value of this parameter consists of string(s) of characters from the document profile character set;
- "copyright dates", specifying the date(s) associated with the copyright by the holder(s) identified by the parameter "copyright information"; the value of this parameter consists of string(s) of characters representing date(s) in accordance with ISO 8601.

5.4.4.2 Status
This attribute specifies the document status, e.g. working paper, draft proposal.
The value of this attribute consists of a string of characters from the document profile character set.

5.4.4.3 User-specific codes
This attribute specifies additional user-specific code(s), e.g. contract number, project number, budget code.
The value of this attribute consists of string(s) of characters from the document profile character set.

5.4.4.4 Distribution list
This attribute specifies a list of the intended recipients of the document.
The value of this attribute consists of one or more entries. Each entry has two optional parameters:
- "personal name of recipient", according to the format specified in Appendix A;
- "recipient's organization", a string of characters from the document profile character set, which indicates information about the organization with which the recipient is associated, e.g. name, address, telephone number.

5.4.4.5 Additional information
This attribute may be used for information that cannot be specified by any other attribute of the document profile.
This attribute can have any value.

5.4.5 External references

5.4.5.1 References to other documents
This attribute specifies reference(s) to any other associated document(s). It consists of one or more entries.
The value of each entry is either an ASN.1 object identifier or a string of characters from the document profile character set.
This value is equal to the value of the document profile attribute "document reference" of the document referred to.

5.4.5.2 Superseded documents
This attribute specifies reference(s) to document(s) superseded by the current document. It consists of one or more entries.
The value of each entry is either an ASN.1 object identifier or a string of characters from the document profile character set.
This value is equal to the value of the document profile attribute "document reference" of the document referred to.
5.4.6 Local file references
This attribute specifies where a copy (copies) of the document may be found. It consists of one or more entries, one for each location where a copy (copies) of the document may be found. Each entry consists of up to three optional parameters, namely
- the file name;
- the location of the document;
- user comments.

The file name is a string of characters that can be used to identify the document uniquely in a filing system. The second parameter specifies the location of the document in a filing system, for example the name of the filing system, the name of the directory and folder in which the document is contained. The third parameter is used to provide user-readable comments.

The value of each parameter is a string of characters from the document profile character set.

5.4.7 Content attributes

5.4.7.1 Document size
This attribute represents the estimated size of the whole document, expressed as a number of 8-bit bytes, where the estimate must not be less than the actual size. The size includes that of the document profile and the document body (if present).

The value of this attribute is an integer, which is not less than the number of 8-bit bytes in the document data stream.

5.4.7.2 Number of pages
This attribute specifies the number of pages in the specific layout structure (if any) of the document.

The value of this attribute is an integer.

5.4.7.3 Languages
This attribute specifies the primary language(s) in which the content of the document is written.

The value of this attribute consists of string(s) of characters from the document profile character set.

5.4.8 Security information
These attributes provide security information only and are not intended to ensure security measures.

5.4.8.1 Authorization
This attribute identifies the person or organization approving or authorizing the document.

The value of this attribute consists either of a personal name with the format specified in Appendix A, or the name of an organization consisting of a string of characters from the document profile character set.

5.4.8.2 Security classification
This attribute specifies the security classification assigned by the document owner(s) relating to such aspects as its visibility, reproduction, storage, audit and destruction requirements.

The value of this attribute consists of a string of characters from the document profile character set.

5.4.8.3 Access rights
This attribute specifies the access right(s) to the document relating to its privacy, as defined by the current owner(s) of the document.

The value of this attribute consists of string(s) of characters from the document profile character set.
Appendix A

Format of personal names

(This Appendix is not part of the Standard)

The format of a personal name consists of a group of up to four parameters:

a) surname;
b) givenname;
c) initials;
d) title.

The “surname” parameter is the family name of a person. This parameter is mandatory.
The “givenname” parameter is the name by which a person is commonly known. This parameter is optional.

The “initials” parameter consists of a sequence of the initial characters of any names other than “surname” and “givenname”, in the order in which they are normally written. This parameter is optional.

The “title” parameter is the title by which a person is normally addressed in office documents. This parameter is optional.

The format of each of the parameters is a string of characters from the document profile character set.

NOTE 4-A1
The format defined above is the same as that given in CCITT Recommendation X.411 (1984).
Appendix B

Minimum set of document profile attributes to be supported by document application profiles

(This Appendix is not part of the Standard)

The document profile attributes listed in table 4–B.1 shall be included in any document profile level defined as a part of a document application profile, subject to the conditions specified in the explanatory notes referred to in the second column of the table.

The requirements for the use of these attributes in an actual instance of interchange of a document profile are indicated by the classifications “M” (mandatory) and “NM” (non–mandatory) in the third column of the table.

Table 4-B.1 (concluded)

Explanatory notes

(1) to be supported only if the document architecture level supports the corresponding constituents;
(2) to be supported only if the document application profile permits references to external document classes;
(3) to be supported only if the document application profile permits references to resource documents;
(4) to be supported only if the document application profile permits documents to act as resource documents;
(5) to be supported only if the document application profile defines any non–standard default values;
(6) to be supported only if the document application profile defines any of the corresponding non–basic features;
(7) to be supported only if the document application profile distinguishes between basic and non–basic numbers of objects per page;
(8) to be supported only if the document application profile supports the corresponding feature;
(9) to be supported only if the document application profile permits character fonts to be designated.
Appendix C

Example of document profile

(This Appendix is not part of the Standard)

NOTE 4-C.1
The following example of a document profile is provided in the form of a table for easy reference back to the sections that describe the attributes. Not all document profile attributes are used in the example.

Part 7 – Raster Graphics Content Architectures
Part 8 – Geometric Graphics Content Architectures

2nd Edition – December 1988
Brief History

In 1985, ECMA/TC29 published Standard ECMA 101, Office Document Architecture, in order to facilitate the interchange of documents.

In the meantime, work has started in ISO and CCITT, resulting in the preparation of ISO 8613, “Office Document Architecture (ODA) and interchange format” and of the CCITT T.410 series, “Open Document Architecture (ODA) and interchange format”. Experts of TC29 participated to the work, and acted as editors of most of the parts of the ISO and CCITT documents.

This second edition of Standard ECMA–101 has been prepared by ECMA/TC29 to align ECMA–101 with the current ISO/CCITT publications.

Development of this ECMA Standard has been in parallel with:

At present this Standard consists of seven parts:
- Part 1, Introduction and General Principles;
- Part 2, Document Structures;
- Part 4, Document Profile;
- Part 5, Open Document Interchange Format (ODIF);
- Part 6, Character Content Architectures;
- Part 7, Raster Graphics Content Architectures;
- Part 8, Geometric Graphics Content Architectures.

At present, there is no part 3. Further parts may be added to this Standard.

This ECMA Standard is published in two volumes: Volume 1, including parts 1, 2 and 4, and Volume 2 including parts 5, 6, 7 and 8. This is Volume 2.

This second edition of ECMA–101 has been approved by the General Assembly of ECMA of 15 December 1988.

Standard ECMA-101 – Open Document Architecture (ODA) and Interchange Format

Part 5 – Open Document Interchange Format (ODIF)

This second edition of Standard ECMA-101 has been prepared by ECMA/TC29 to align ECMA-101 with the current ISO/CCITT publications.

At present this standard consists of seven parts:
- Part 1, Introduction and General Principles;
- Part 2, Document Structures;
- Part 4, Document Profile;
- Part 5, Open Document Interchange Format (ODIF);
- Part 6, Character Content Architectures;
- Part 7, Raster Graphics Content Architectures;
- Part 8, Geometric Graphics Content Architectures.

At present, there is no part 3.

Further parts may be added to this ECMA Standard.

This part 5 contains four Appendices:
- Appendix A: Coded Representation;
- Appendix B: Application Class Tag Assignment;
- Appendix C: Summary of the ASN.1 Object Identifier Value Assignment;
- Appendix D: Examples.
1. **SCOPE**

The purpose of this International Standard is to facilitate the interchange of documents.

In the context of this Standard, documents are considered to be items such as memoranda, letters, invoices, forms and reports, which may include pictures and tabular material. The content elements used within the documents may include graphic characters, geometric graphics elements and raster graphics elements, all potentially within one document.

**NOTE 5-1**
This Standard is designed to allow for extensions, including typographical features, colour, spreadsheets and additional types of content such as sound.

This Standard applies to the interchange of documents by means of data communications or the exchange of storage media.

This Standard provides for the interchange of documents for either or both of the following purposes:
- to allow presentation as intended by the originator;
- to allow processing such as editing and reformatting.

The composition of a document in interchange can take several forms:
- formatted form, allowing presentation of the document;
- processable form, allowing processing of the document;
- formatted processable form, allowing both presentation and processing.

This Standard also provides for the interchange of ODA information structures used for the processing of interchanged documents.

Furthermore, this Standard allows for the interchange of documents containing one or more different types of content such as character text, images, graphics and sound.

This part of ECMA–101 defines:
- the format of the data stream used to interchange documents structured in accordance with Part 2 of this Standard;
- the representation of the constituents which may appear in an interchanged document.

**NOTES 5-2**
This part of this Standard does not specify the coded representation of content elements.

**NOTE 5-3**
Data formats for presentation attributes and coding attributes are defined in other parts of this Standard.

2. **REFERENCES**

ECMA–101, 1989 – *Office Document Architecture (ODA) and Interchange Format – Part 1 – Introduction and general principles; Part 2 – Document structures; Part 4 – Document profile; Part 6 – Character content architectures; Part 7 – Raster graphics content architectures; Part 8 – Geometric graphics content architectures.*

ISO 8601, : Data elements and interchange formats – Information interchange – Representation of dates and times.

3. DEFINITIONS
For the purpose of this part of this Standard, the definitions given in Part 1 of this Standard apply.

4. DOCUMENT REPRESENTATION
A document structured in accordance with this Standard is represented for interchange by the Open Document Interchange Format (ODIF).
ODIF is an abstract data syntax in which the constituents and attributes of the document are represented by a hierarchy of data structures and data items, specified using the abstract syntax notation ASN.1 defined in ISO 8824.
The coded representation of each data structure or data item is obtained by applying a set of encoding rules.
ODIF is specified in clause 5.

NOTE 5–4
ASN.1 is a formal description method that allows data types relevant to an application to be specified in terms of other data types, including basic data types such as “integer” and “octet string” which are defined in ISO 8824 itself. Basic encoding rules for ASN.1 are defined in ISO 8825 and are summarized in Appendix A.

5. OFFICE DOCUMENT INTERCHANGE FORMAT (ODIF)

5.1 General description
A document structured in accordance with this Standard is represented by a data stream consisting of one or more data structures of the following types:
- document profile descriptor;
- layout object descriptor;
- layout object class descriptor;
- logical object descriptor;
- logical object class descriptor;
- presentation style descriptor;
- layout style descriptor;
- text unit.

These data structures are called interchange data elements. Within a data stream, the interchange data elements are ordered in accordance with certain rules which are specified below. This part of this Standard defines two such sets of rules; they are called interchange format class A and interchange format class B.
Which of these sets of rules applies to a given data stream is indicated in the document profile descriptor. In all cases, a data stream contains one and only one document profile descriptor which is always the first interchange data element in the data stream. The document profile descriptor may be the only data structure in the data stream.
When an ODIF data stream is used as part of an ASN.1 external data type, the abstract syntax shall be formed by an ASN.1 SEQUENCE–OF type; referencing to the interchange data element type and the encoding of the data value shall consist of an integral number of octets, formed by applying the ASN.1 basic encoding rules; and the value of the associated ASN.1 object identifier shall be { 2 8 0 0 }.

NOTE 5–5
The manner of incorporating the interchange data elements, or the external data type, in an application protocol or the manner of mapping them on service data units (in an OSI environment) is not defined by this part of this Standard.

5.2 Interchange format class A
According to interchange format class A, a data stream consists of one document profile descriptor and, optionally, one or more interchange data elements of the following types:
- layout object descriptor;
- layout object class descriptor;
- logical object descriptor;
- logical object class descriptor;
- presentation style descriptor;
- layout style descriptor;
- text unit.

The order of the interchange data elements is as follows:

a) document profile descriptor;
b) layout object class descriptors;
c) logical object class descriptors;
d) text units representing generic content portions;
e) presentation style descriptors;
f) layout style descriptors;
g) layout object descriptors;
h) logical object descriptors;
i) text units representing specific content portions.

Within each of the groups of layout object descriptors and logical object descriptors, the order of the descriptors is equal to the sequential order defined in Part 2 of this Standard.

If the data stream contains layout object descriptors, the text units representing specific content portions are ordered according to the sequential layout order; otherwise, they are ordered according to the sequential logical order.

Within each of the other groups of interchange data elements, the order is arbitrary.

5.3 **Interchange format class B**

According to interchange format class B, a data stream consists of one document profile descriptor and, optionally, one or more interchange data elements of the following types:

- layout object descriptor;
- layout object class descriptor;
- presentation style descriptor;
- text unit.

Interchange format class B can be used only to represent documents that do not contain any specific or generic logical structure, i.e. documents that conform to the formatted document architecture class.

The order of the interchange data elements is as follows:

a) document profile descriptor;
b) layout object class descriptors and associated text units;
c) presentation style descriptors;
d) layout object descriptors and associated text units.

Within the group of layout object class descriptors and associated text units, the order is such that a group of descriptors that have identical identifiers, except for the last number in each identifier, follow each other in the data stream without any other descriptor between them. However, each descriptor of an object class for a basic layout object is followed immediately by the associated text units.

Within the group of layout object descriptors and associated text units, the order of the descriptors is equal to the sequential order defined in part 2 of this Standard. However, each descriptor of a basic layout object is followed immediately by the associated text units.

Within the group of presentation style descriptors, the order is arbitrary.

5.4 **Descriptors and text units**

A document profile descriptor, layout object descriptor, layout object class descriptor, logical object descriptor, logical object class descriptor, presentation style descriptor or layout style descriptor consists of simple and composite data items representing the attributes of the constituent concerned. The document profile, each object class, each style and each object is represented by one descriptor.
A text unit consists of two parts:

a) an attribute field, i.e. a data structure consisting of simple and composite data items representing the attributes of the content portion concerned;

b) an information field, i.e. a data structure that is either a data item or a set of data items representing the content elements making up the content portion concerned.

Each content portion is represented by one text unit.

The data formats of the interchange data elements are specified in 5.5 to 5.12, using the abstract syntax notation ASN.1 defined in ISO 8824.

NOTE 5–6
Subclauses 5.5 to 5.12 by themselves do not completely define the data stream format; additional rules are specified in 5.1 to 5.4 of this part and in other parts of this Standard. For example, the keyword OPTIONAL merely indicates that a particular data structure or data item is not part of every instance of the containing data structure; the conditions controlling the presence or absence of the data structure or data item are specified in part 2 or part 4.

Appendix A

Coded Representation

(This Appendix is not part of the Standard)

This Appendix is a summary of the basic encoding rules for the abstract syntax notation ASN.1 defined in ISO 8825.

The coded representation of each data structure or data item that constitutes, or constitutes part of, a descriptor or a text unit consists of a type field, a length field and a value field.

If the data item concerned is an elementary data item, then the type field specifies the elementary data type, the length field specifies the length of the value field, and the value field represents the value of the data item.

If the data structure or data item concerned is not elementary, then the type field identifies the attribute or group of attributes corresponding to the data structure or data item, the length field specifies the length of the value field, and the value field consists of one or more triplets, each of which is composed of a type field, a length field and a value field, representing the subordinate data structures and data items.

The type field (which is called "identifier octets" in ISO 8825) consists of one or more bytes. The bits of the first byte are used as follows:

- bits 8 and 7: tag class (00: universal,
  01: application,
  10: context-specific,
  11: private);
- bit 6: contents encoding form (0: simple,
  1: structured);
- bits 5 to 1: 00000 to 11110: tag number;
  11111 indicates a multi-octet type field.

The following tag numbers for universal tags have been assigned in ISO 8824 and ISO 8825:

<table>
<thead>
<tr>
<th>Built-in data types</th>
<th>Defined data types</th>
</tr>
</thead>
<tbody>
<tr>
<td>0: End-of-contents</td>
<td>18: Numeric String</td>
</tr>
<tr>
<td>1: Boolean</td>
<td>19: Printable String</td>
</tr>
<tr>
<td>2: Integer</td>
<td>20: Teletext String</td>
</tr>
<tr>
<td>3: Bit String</td>
<td>21: Videotext String</td>
</tr>
<tr>
<td>4: Octet String</td>
<td>22: IA5 String</td>
</tr>
<tr>
<td>5: Null</td>
<td>23: UTC Time</td>
</tr>
<tr>
<td>6: Object Identifier</td>
<td>24: Generalized Time</td>
</tr>
<tr>
<td>7: Object Descriptor</td>
<td>25: Graphic Character String</td>
</tr>
<tr>
<td>8: External</td>
<td>26: General String</td>
</tr>
<tr>
<td>9: Real</td>
<td>27: Visible String</td>
</tr>
<tr>
<td>10:Enumerated</td>
<td></td>
</tr>
<tr>
<td>11: Encrypted</td>
<td></td>
</tr>
<tr>
<td>16: Sequence</td>
<td></td>
</tr>
<tr>
<td>17: Set</td>
<td></td>
</tr>
</tbody>
</table>

Data items of type End-of-contents, Boolean, Integer or Null are simple (elementary data items). Sequences and Sets are structured (data structures with subordinate data items). Data items of type Bit String, Octet String or any of the defined data types can be either simple or structured.
The length field consists of one or more bytes. It takes one of three forms: short, long and indefinite. The bits of the first byte are used as follows:

bit 8:       length field form (0: short, 1: long or indefinite)
bits 7 to 1: if bit 8 = 0: number of bytes of the value field;
              if bit 8 = 1: number of bytes of the length field following the first byte;
              00000000 indicates the indefinite form of the length field.

A data structure or data item with an indefinite length field must be structured and must be terminated by a delimiter consisting of an End-of-contents (EOC) item. An EOC item consists of two bytes: a type field of one byte and a length field of one byte. Both are equal to zero. An EOC item has no value field.
Appendix B

Application Class Tag Assignments

(This Appendix is not part of the Standard)

The application class tag assignments made in various clauses of this part of this Standard are summarized in the table below:

<table>
<thead>
<tr>
<th>Tag</th>
<th>Data type</th>
<th>Clause</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPLICATION 0</td>
<td>Content–Portion–Identifier</td>
<td>5.7</td>
</tr>
<tr>
<td>APPLICATION 1</td>
<td>Object–or–Class–Identifier</td>
<td>5.7</td>
</tr>
<tr>
<td>APPLICATION 2</td>
<td>Content–Type</td>
<td>5.10</td>
</tr>
<tr>
<td>APPLICATION 3</td>
<td>Character–Data</td>
<td>5.6</td>
</tr>
<tr>
<td>APPLICATION 4</td>
<td>Date–and–Time</td>
<td>5.6</td>

<tr>
<td>APPLICATION 5</td>
<td>Style–Identifier</td>
<td>5.7</td>
</tr>
<tr>
<td>APPLICATION 6</td>
<td>Personal–Name</td>
<td>5.6</td>
</tr>
</tbody>
</table>
Appendix C

Summary of ASN.1 Object Identifier Value Assignment

(This Appendix is not part of the Standard)

Values of ASN.1 object identifiers are assigned in various clauses in this part of this Standard. These are summarized below.

<table>
<thead>
<tr>
<th>Object identifier</th>
<th>Meaning</th>
<th>Clause value</th>
</tr>
</thead>
<tbody>
<tr>
<td>{2800}</td>
<td>Identifies External data type</td>
<td>5.1</td>
</tr>
<tr>
<td>{28155}</td>
<td>Identifies Module Interchange–Data–Elements</td>
<td>5.5</td>
</tr>
<tr>
<td>{28156}</td>
<td>Identifies Module Document–Profile–Descriptor</td>
<td>5.6</td>
</tr>
<tr>
<td>{28157}</td>
<td>Identifies Module Identifiers–and–Expressions</td>

<tr>
<td>{281511}</td>
<td>Identifies Module Default–Value–Lists</td>
<td>5.11</td>
</tr>
<tr>
<td>{281512}</td>
<td>Identifies Module Text–Units</td>
<td>5.12</td>
</tr>
</tbody>
</table>
Appendix D

Examples of ODIF Data Streams

(This Appendix is not part of the Standard)

The first four examples in this Appendix consist of data streams representing various versions of the sample document in Appendix B of part 2 of this Standard.

Four versions of the sample document are considered:

- Example 1: specific layout structure only. This example is specified by clause B.4.1, including figure 2–B.7 and table 2–B.1, of part 2 of this standard.
- Example 2: specific logical structure only. This example is specified by clause B.4.2, including figure 2–B.8 and tables 2–B.2, B.3 of part 2 of this Standard.
- Example 3: specific logical structure, generic logical structure and generic layout structure. This example is specified by clause B.5, including figures 2–B.8, 2–B.9, 2–B.10, and tables 2–B.4, 2–B.5, 2–B.6, 2–B.7 of part 2 of this Standard.
- Example 4: specific layout structure only, as generated from the structures in example 3. This example is specified by clause B.6, including figure 2–B.11 and table 2–B.8, of part 2 of this Standard.

The four examples are presented in clauses D.1, D.2, D.3 and D.4 below. The data stream constituting each example is shown in two forms of notation:

a) the ASN.1 notation for data values defined in ISO 8824;
b) the hexadecimal notation of the encoded data values, after applying the basic encoding rules defined in ISO 8825.

The ASN.1 notation is shown on the left and the hexadecimal notation is shown on the right of each page. The symbol LL represents a length field of which the length is unknown.

In addition, clause D.5 presents an example consisting of a data stream representing the sample document profile in Appendix C of part 4 of this Standard.
D.1 Example 1: Sample document from Appendix B of part 2 of this Standard;
Specific layout structure only

Standard ECMA–101 – Open Document Architecture (ODA) and Interchange Format

Part 6 – Character Content Architectures

This second edition of Standard ECMA–101 has been prepared by ECMA/TC29 to align ECMA–101 with the current ISO/CCITT publications.

At present this standard consists of seven parts:
- Part 1, Introduction and General Principles;
- Part 2, Document Structures;
- Part 4, Document Profile;
- Part 5, Open Document Interchange Format (ODIF);
- Part 6, Character Content Architectures;
- Part 7, Raster Graphics Content Architectures;
- Part 8, Geometric Graphics Content Architectures.

At present, there is no part 3.

Further parts may be added to this ECMA Standard.

This part 6 contains four Appendices:
- Appendix A: Presentation Attributes and Control Functions;
- Appendix B: Character Content Architecture Levels;
- Appendix C: Coded Representation of Control Functions;
- Appendix D: Summary of ASN.1 Object Identifiers.
1. **SCOPE**

The purpose of Standard ECMA–101 is to facilitate the interchange of documents. In the context of this Standard, documents are considered to be items such as memoranda, letters, invoices, forms and reports, which may include pictures and tabular material. The content elements used within the documents may include graphic characters, geometric graphic elements and raster graphic elements, all potentially within one document.

*NOTE 6–1*

This Standard is designed to allow for extensions, including typographical features, colour, spreadsheets and additional types of content such as sound.

This Standard applies to the interchange of documents by means of data communications or the exchange of storage media.

It provides for the interchange of documents for either or both of the following purposes:

- to allow presentation as intended by the originator;
- to allow processing such as editing and reformatting.

The composition of a document in interchange can take several forms:

- formatted form, allowing presentation of the document;
- processable form, allowing processing of the document;
- formatted processable form, allowing both presentation and processing.

This Standard also provides for the interchange of ODA information structures used for the processing of interchanged documents.

Furthermore, this Standard 8613 allows for the interchange of documents containing one or more different types of content such as character text, images, graphics and sound.

This part of ECMA–101:

- defines character content architectures that can be used in conjunction with the document architecture defined in part 2 of this Standard;
- defines the internal structure of content conforming to these character content architectures;
- defines those aspects of positioning and imaging applicable to presentation of these character content architectures in a basic layout object;
- defines the presentation attributes and control functions applicable to these character content architectures;
- describes a content layout process which, together with the document layout process described in part 2 of this Standard, determines the layout of character content in basic layout objects and the dimensions of these basic layout objects.

2. **REFERENCES**

ECMA-6 : 1985, 7-bit coded character set for information interchange.

ISO 6937 : 1983, Information processing – Coded character sets for text communication.

3. DEFINITIONS
For the purpose of this part of this Standard, the definitions given in part 1 of this Standard apply.

4. GENERAL PRINCIPLES

4.1 Classes
Three classes of character content architecture are distinguished:
- a character content architecture for formatted content which allows for document content to be presented (e.g. printed or displayed) as intended by the originator. Formatted content can be used in any basic component;
- a character content architecture for processable content which allows for document content to be processed (e.g. edited or formatted). Processable content can be used in any basic logical component;
- a character content architecture for formatted processable content which allows for document content to be processed and also to be presented as intended by the originator. Formatted processable content can be used in any basic component.

4.2 Content
The content of a basic component that conforms to a character content architecture is a character string. This character string is formed by concatenating the character strings in the content portions of the basic component.
The content character string consists of a combination of graphic characters, control functions and space characters.

4.3 Presentation attributes
Presentation attributes are applicable to basic logical and layout components. They contain information that specifies the initial conditions relating to the layout, the imaging and the selection of graphic characters of the content of these basic components. Some of these conditions can be changed by control functions contained within the content.
Presentation attributes are classified as follows:
- logical presentation attributes which can be associated with processable and formatted processable character content. These attributes take effect during the content layout process but are ignored during the content imaging process;
- layout presentation attributes which can be associated with formatted and formatted processable character content. These attributes take effect during the content imaging process. They are generated either by a content layout process or by a process that creates or edits the formatted or formatted processable content;
- shared presentation attributes which can be associated with all character content architecture classes. These attributes take effect during either or both the content layout and imaging processes.

NOTE 6–2
Presentation attributes can be applied to the content of a basic component in one of three ways. They can be specified directly in an object or object class description or they can be specified by means of a presentation style associated with the object or object class description. Alternatively, they can be indirectly applied to an object or object class by means of a default value list (see part 2 of this Standard).

4.4 Control functions
Control functions with zero or more parameters may specify information relating to the layout or imaging of subsequent graphic characters. A control function can also be used to extend or replace the set of graphic characters being used. The scope of all control functions is limited to the basic component in which they occur.
Classification of control functions is similar to that of presentation attributes:
- logical control functions which can be used in processable and formatted processable character content. These control functions take effect during the content layout process but are ignored during the content imaging process;
layout control functions which can be used in formatted and formatted processable character content. These control functions take effect during the content imaging process. They are generated by the content layout process. Alternatively, they may be inserted by a process (not described in this Standard) that creates or edits the formatted or formatted processable content;

- shared control functions which can be used in all character content architecture classes. These control functions take effect during either or both the content layout and imaging processes.

In addition, formatted processable content may contain control functions known as delimiters. These delimiters are used to indicate a string of one or more graphic characters and/or control functions that have been inserted as the result of a content layout process (see clause 12). The delimited graphic characters and/or control functions take effect only during the content imaging process. The delimiters take effect during the content layout process by deleting them and the enclosed character sequence.

4.5 Graphic characters

The set of graphic characters used in the content of a basic component, and their coded representation, are specified by presentation attributes and code extension control functions (see clause 10 and 11.1.17).

Any set or sets of graphic characters may be used in the content of basic components, subject to the restrictions associated with the particular content architecture in use and subject to proper designation and invocation in accordance with ISO 2022.

Any non-spacing characters included in a graphic character set are not to be used in isolation but only in combination with spacing characters.

4.6 Space characters

The character SPACE (SP) is considered both as a logical control function and as a graphic character. As a graphic character, it has a graphical representation consisting of the absence of a graphic symbol. As a control function, it indicates a potential line break point (see 12.2.1.3.2).

NOTE 6–3

NBSP (No Break SPace) and any fixed-width space characters, such as “digit space”, “em space” and “en space” are regarded as graphic characters i.e. are not regarded as line break points.

4.7 Coding of content information

The coded representation of the content information within a content portion is in accordance with the rules specified in ISO 2022.

Coded representations of control functions are defined in ISO 6429 and are summarised in Appendix C.

4.8 Internal structure

4.8.1 Formatted content

Formatted content is content for which all the necessary information relating to the layout and imaging of that content has been specified. Content in this form is intended to be imaged as specified and is not intended to be revised by an editing process or to be reformatted.

The content of a basic component conforming to a formatted character content architecture consists of one or more lines of characters. Each pair of successive lines is separated by a hard line terminator. The last (or only) line may or may not be terminated by a hard line terminator; the end of the content of a basic component implicitly terminates the last line.

4.8.2 Processable content

Processable content is content which has not been laid out. Content in this form is suitable for revision by an editing process.

NOTE 6–4

The editing process is implementation dependent and is not described in this Standard.

In order to image content in this form, it is necessary to apply a content layout process (see clause 12) to the content which converts the processable content into formatted content (see 4.8.1) or into formatted processable content (see 4.8.3).
To assist the processing (i.e., editing or layout processes) of processable content, a number of logical presentation attributes and control functions have been defined (see clauses 7 and 11). In addition, the character SPACE is regarded as both a graphic character and as a control function that indicates where a line break may occur when the content is laid out.

The content of a basic component conforming to a processable character content architecture consists of one or more sequences of characters. Each pair of successive character sequences is separated by a hard line terminator control function. The last (or only) character sequence may or may not be terminated by a hard line terminator.

If the hard line terminator is omitted at the end of the content of a basic logical component to which another basic logical component is concatenated (see part 2 of this Standard), then the last character sequence continues into the content of the next basic logical component. In all other cases, the end of the content of the basic logical component implicitly terminates the last character sequence.

The division into character sequences represents the internal structure of the processable content of a basic logical component. Each character sequence is anonymous, in that no name or identifier is associated with it, and no relationship exists among character sequences except that of sequence.

4.8.3 Formatted processable content

Formatted processable content is content that is structured such that it contains both the formatted content and the processable content as subsets. It is identical in structure to the processable content, except that it may contain additional control functions and graphic characters that have been added as a result of the content layout process. It is identical in structure to the formatted content, except that it may contain logical control functions and delimiters.

Thus, formatted processable content can be converted to processable content by deleting (or ignoring) all layout control functions, all occurrences of the delimiters and all control functions and characters within those delimiters.

Alternatively, formatted processable content can be converted to formatted content by deleting (or ignoring) all logical control functions and the delimiters but retaining the control functions and characters within the delimiters.

NOTE 6–5
The conversion of formatted processable content to processable content is a reversible process (providing the same layout constraints are applicable to the content layout process) but converting formatted processable content to formatted content is irreversible.

The formatted view of a basic component conforming to a formatted processable character content architecture consists of one or more lines of characters. Each pair of successive lines is separated by either a hard or soft line terminator. The last (or only) line may or may not be terminated by a hard line terminator; the end of the content of a basic layout component implicitly terminates the last line.

The processable view of a basic component conforming to a formatted processable character content architecture consists of one or more sequences of characters. Each pair of successive character sequences is separated by a hard line terminator. The last (or only) character sequence may or may not be terminated by a hard line terminator.

If the hard line terminator is omitted at the end of the content of a basic logical component to which another basic logical component is concatenated (see part 2 of this Standard), then the last character sequence continues into the content of the next basic logical component. In all other cases, the end of the content of the basic logical component implicitly terminates the last character sequence.

Soft line terminators are used as separators between lines within a character sequence. The division into character sequences represents the internal structure of the content of a basic logical component. Each character sequence is anonymous, in that no name or identifier is associated with it, and no relationship exists among character sequences except that of sequence.

5. CHARACTER POSITIONING

This clause specifies how characters are to be positioned within a basic layout object. The intention is to aid understanding of the presentation attributes and control functions that relate to character positioning.
This clause provides for the positioning of any font that is defined in accordance with ISO 9541-5. This clause also caters for the positioning of characters pertaining to different fonts within the same basic layout object.

5.1 Basic concepts

5.1.1 Character fonts

In the context of this part of this Standard, the term graphic character is used in its abstract sense; that is, this term refers to a member of a set of graphic symbols used for the representation of information. The term character image is then used to refer to the rendition of a graphic character on a presentation medium.

A font is a set of character images, normally with a common design and size. A set of font attributes is associated with the font as a whole and a set of character attributes is associated with each individual character. These attributes are defined in ISO 9541-5.

The main purpose of the font attributes is for the recipient to identify the font used by the originator and, in case the specified font is not available, the font and character attributes serve as a guidance for the recipient to find an appropriate substitute font among those available.

Further information concerning the designation and invocation of different fonts within a basic object is given in clause 6.

5.1.2 Directions

In the context of this part of this Standard, all directions are expressed as counter clockwise angles of rotation (in degrees) relative to a specified reference direction (an example is given in figure 6–1).

The character path is the direction of progression of successive character images within a line box (defined in 5.1.7) and is expressed as a direction relative to the horizontal direction of the layout object (see figure 6–4).

The line progression is the direction of progression of successive line boxes within the basic layout object and is expressed as a direction relative to the character path (see figure 6–11).

The character orientation is the direction of the character baseline (defined in 5.1.3) relative to the character path.

Only one value for the character path, line progression and character orientation may be specified for a basic component.

![Figure 6–1 – Example of direction](image)

5.1.3 Character image model

The position point is a reference point associated with a character image (see figure 6–2). It is used for the positioning of the character image within a line box. The escapement point is a reference point associated with a character image (see figure 6–2). It is used for the positioning of the next character image.

The character baseline is an imaginary line across a character image, for the purpose of defining the character orientation. The character baseline is a horizontal line when the character image is in its intended viewing orientation (see figure 6–3).
Figure 6–2 – Illustration of kerns

A position point and escapement point must be defined for each character orientation which is intended to be used (see figure 6–3); i.e. “writing modes” corresponding to the required character orientations must be defined in the font description, or fall-backs must be defined in document application profiles.

A kern is that part of the character image that extends beyond its position and escapement points (see figure 6–2).
5.1.4 Character spacing
The concept of character spacing is only applicable when a constant spacing font is selected. It is used (in conjunction with the inter-character space) to determine the distance between character images within a line box as defined in 5.2.1.
The character spacing is equal to the distance between the position points of successive character images when the inter-character space is zero.
The character spacing is independent of the distance between the position point and escapement point of character images.

5.1.5 Active position
The active position is an abstraction of an imaging device concept such as a cursor. This concept is used in the definitions of control functions (see 11) where a sequential method of processing a character string is assumed.
The active position indicates the point, within the positioning area of a basic layout object, at which the action specified by the next character (graphic character or control function) is to be effected.
If the next character is a graphic character, its character image is positioned with the position point at the active position and the active position is advanced in the direction of the character path by the amount of spacing defined in 5.2.1. If the next character is a control function, this may cause the active position to move to another point within the positioning area.

5.1.6 Positioning area
A positioning area is a rectangular area, wholly contained within a basic layout object, within which position points and escapement points are to be positioned (see figure 6–4). Kerns of character images are permitted to extend beyond the positioning area but are not permitted to extend beyond the edges of the basic layout object.
Two of the edges of the positioning area are referred to as the start edge and end edge (see figure 6-4). The start edge and the end edge are defined such that the direction from the start edge to the end edge is in the direction of the character path.

The other two edges of the positioning area are referred to as the top edge and bottom edge (see figure 6-11). The top edge and the bottom edge are defined such that the direction from the top edge to the bottom edge is in the direction of line progression.

The start and end edges are indented from the corresponding edges of the basic layout object by a distance referred to as the kerning offset (see figure 6-4). The kerning offset specified depends upon the fonts of the characters to be positioned in the positioning area. Its value is chosen such that no part of any character image with kers will extend beyond the boundary of the basic layout object when sequences of character images are positioned within it.

5.1.7 Line boxes

Within the positioning area, a sequence of character images is positioned within an area called a line box (see figure 11). Each line box is a rectangular area that extends from the start edge to the end edge of the positioning area.

Each line box contains a reference point called the line home position (see figure 6-4). This point is used for positioning the line box within the basic layout object. It also serves as the active position for the first graphic character or control function in each line.

Each line box contains an imaginary line called a reference line (see figure 6-4). The reference line passes through the line home position in the direction of the character path. It extends from the start edge to the end edge within the line box and is used for the alignment of character images.

The length of the line box is equal to the distance between the start and end edges. The width (or height) of a line box is equal to the sum of the line box forward extent and the line box backward extent (see figure 6-4). The line box backward extent is the distance between the reference line and the edge of the line box in the direction opposite to the direction of line progression. The line box forward extent is the distance between the reference line and the edge of the line box in the direction of line progression.

The values of the forward and backward extents depend on the maximum extents (measured perpendicular to the reference line) of the character fonts used in the line box. Determination of the forward and backward extents take into account any displacements of character images perpendicular to the character path, e.g. for subscripts, superscripts and parallel annotation.

NOTE 6-6

As an example, for a Latin font with character path 0°, line progression 270° and when a single font is used in the line box, then the forward and backward extents are equal to the maximum right and maximum left extents for that font as defined in ISO 9541-5.
5.2 Positioning of character images within a line box
Successive character images are positioned within a line box in the direction of the character path. The position points of the character images are aligned on the reference line unless the characters are imaged as subscripts, superscripts or parallel annotation. There are several factors which affect the positioning of character images along the reference line:
- spacing between characters;
- alignment;
- tabulation;
- character ordering;
- parallel annotation;
- subscript/superscript;
- pairwise kerning;
- first line offset;
- itemisation.
5.2.1 Spacing between characters

The *inter-character space* is an additional amount of spacing between the position points of successive character images, in the direction of the character path (see 5.1.4). A negative value indicates a reduction in the spacing between successive character images.

The distance between the position points of successive character images may be constant or variable depending upon the font as follows:

- For fonts with *constant spacing*, the distance between the position points of successive character images is independent of the characters and is the sum of the character spacing (as specified by presentation attributes and control functions) and the inter-character space (see figure 6-5).
- For fonts with *variable spacing*, the distance between the position points of successive character images is dependent upon the character i.e. normally the distance between the position point and the escapement point of a character, and is the sum of the net escapement of the character (as specified by the font) and the inter-character space (see figure 6-6).

The space width, i.e. the width of the SP (Space) character image, is determined as follows:

- for any SP that follows a soft line terminator and precedes the first graphic character of a line, or precedes a soft line terminator and follows the last graphic character of a line, the width is equal to zero;
- in a constant spacing font, the default width equals the character spacing;
- in a variable spacing font, the width is implicitly defined by the font;
- for all fonts, the width may be specified by a control function.

---

**character path**

figure 6-5 – Spacing for constant spacing font

**figure 6-6 – Spacing for variable spacing font**
5.2.2 Alignment
The character images are positioned within a line box in accordance with the alignment attribute as follows:

- start-aligned: the position point of the first character image is placed at the line home position;
- end-aligned: the escapement point of the last character is placed at the end edge of the positioning area;
- centred: the distance from the line home position to the position point of the first character image is approximately equal to the distance from the escapement point of the last character image to the end edge of the positioning area;
- justified: the position point of the first character image is placed at the line home position and the escapement point of the last character image is coincident with the end edge of the positioning area by appropriately setting the space width and/or the inter-character space.

5.2.3 Tabulation
The position of character images along a reference line can be controlled by means of a set of tabulation stops. Each tabulation stop specifies a point along a reference line relative to the start edge of the positioning area.

A string of character images can be placed at a tabulation stop by means of a control function embedded in the text. The string may be start-aligned, end-aligned, centred or aligned around one or more specified characters within that string as follows (see figure 6-7):

- start-aligned: the position point of the first character image of the string is placed at the tabulation stop;
- end-aligned: the escapement point of the last character image of the string is placed at the tabulation stop;
- centred: the string is placed such that the position point of the first character image and the escapement point of the last character image of the string are approximately equi-distant from the tabulation stop;
- aligned around: the position point of the first character image of the first instance of the specified group of characters in that string is positioned at the tabulation stop. If the specified group of characters does not appear in the text associated with that tabulation stop, then the alignment defaults to end-aligned as defined above.

Figure 6-7 - Tabulation
5.2.4 Character ordering

Within the content of a basic object, the interchange order is always the reading order of the language used.

In the case of certain languages e.g. Arabic and Hebrew, where the alphanumeric text is read from right to left and the numeric text is read from left to right, the interchanged stream must indicate the change in presentation direction at the appropriate point(s).

This is necessary since control functions in character content architectures are defined to operate sequentially according to their position in the character stream.

When a string of characters with reversed presentation direction is embedded in the text with normal presentation direction, the image of the last character of the string with reversed presentation direction is positioned adjacent to the image of the last character of the preceding string with normal presentation direction (see figure 6–8).

*NOTE 6–7*

In figure 6–8, the terms “first” and “last” are used in relation to the interchange order and the terms “normal” and “reversed” in relation to the direction of the character path.

\[ \text{Interchange order} = \text{ABCDE123FGH} \]

\[ \square = \text{control function to reverse presentation direction} \]

\[ \text{P/D} = \text{presentation direction} \]

\[ \text{HGF123EDCBA} \]

\[ \text{character path} \]  \[ \text{last character of normal P/D} \]  \[ \text{last character of reversed P/D} \]  \[ \text{first character of reversed P/D} \]  \[ \text{first character of next normal P/D} \]

**Figure 6–8 – Character ordering**

5.2.5 Parallel annotation

Two sequential character strings may be delimited such that the second string is used to indicate the pronunciation and interpretation of the first. It is intended to be used in the Japanese language to provide pronunciation and interpretation information (Ruby) in the form of Kana character(s) for one or more Kanji characters. This is indicated in the formatted text by the Kana character(s) being centred either above or to the right of the Kanji character(s), for character image orientations orthogonal and parallel to the character path respectively (see figure 6–9).

Where centring would result in Kana characters being positioned outside the positioning area, then the Kana character string is positioned such that it is start-aligned or end-aligned with the edge of the available area.
where: HPB, HPR, VPB, VPR  
SOS, ST, PTX  
xx, x'x', yy  
control functions (see clause 11)  
parameter values determined by the content layout process

The current reference point moves from "a", "b", "c' and returns to "a".  

Figure 6-9 – An example of the specification of Japanese Ruby
5.2.6 **Subscript/superscript**

Subscript rendition allows for the active position to be displaced from the reference line in the direction of line progression.

Superscript rendition allows for the active position to be displaced from the reference line in the direction opposite to that of line progression.

The combined effect of all subscript/superscript renditions within a line box must be such that the active position is returned to the reference line before the occurrence of a hard or soft line terminator.

5.2.7 **Pairwise kerning**

Pairwise kerning allows for the moving of the active position from that defined by the preceding character. The distance and direction depend both on the character being imaged and the preceding character.

In the case of a constant spacing font, pairwise kerning is ignored.

In the case of a variable spacing font, the actual distance between the escapement point of one character image and the position point of the next character image is modified by the kerning information as defined in the character attributes of the font.

5.2.8 **First line offset**

First line offset allows for character imaging of the first line of a basic component to start at a position displaced from the line home position.

The offset is either in the direction of the character path (producing first line indentation) or in the direction opposite to the character path (producing overhang) as illustrated in figure 6–10.

5.2.9 **Itemisation**

Itemisation allows for imaging of an *item identifier* on the first line of a basic component in positions which are not directly constrained by the line home position and the first line offset (see figure 6–10).

An item identifier is a string of characters that precedes and is separated from the remainder of the first line of a basic component.

A start offset and an end offset are defined relative to the line home position. These offsets determine the location of the item identifier and the separation between the item identifier and the line home position.

The item identifier may be positioned on the first line in accordance with the item identifier alignment attribute as follows:

- *start-aligned*: the position point of the first character image of the item identifier is placed at the start offset;

- *end-aligned*: the escapement point of the last character image of the item identifier is placed at the end offset.
Figure 6-10 – Illustration of itemisation, first line offset and indentation
5.3 Positioning of line boxes within a basic layout object

For positioning of line boxes in a basic layout object, the area of that object is independent of any adjoining areas. No part of the image is permitted to extend beyond the boundaries of the basic layout object.

The *initial point* is the point relative to which all line boxes are positioned within the basic layout object (see 7.2.2 and figure 6–11).

The line home position of the first line box is at the initial point of the basic layout object. Subsequent line home positions are located on a line through the initial point in the direction of line progression.

The distance between the line home positions of two successive line boxes is determined as follows:

- When proportional line spacing is to be performed, the distance between the reference lines of two successive line boxes is evaluated by an implementation dependent algorithm not defined in this Standard;

- When proportional line spacing is not to be performed, the distance between the reference lines of two successive line boxes is equal to the current line spacing as specified by presentation attributes and control functions.

![Diagram](image.png)

*Figure 6–11 – Illustration of line box positioning concepts*
6. CHARACTER IMAGING

Four groups of specifications may apply to the imaging of graphic character elements in a basic object, namely those relating to:

- emphasis;
- font selection;
- subscript and superscript;
- character combinations.

These groups of specifications are defined below.

NOTE 6–8
Emphasis (by ‘weight’, ‘posture’ etc.) and subscript/superscript rendition may be achieved by font selection.

NOTE 6–9
Document application profiles may define additional restrictions on the use of the character features defined in this clause. In addition, an implementation may replace an imaging feature by an alternative fall–back feature. However, this Standard does not define preferred fall–back features. It should also be noted that use of a fall–back feature may cause incorrect or misleading information to be conveyed to the user. It is particularly recommended that a fall–back is not used when the feature ‘crossed–out’ is specified (see 6.1.6).

6.1 Emphasis

Portions of text may be visually differentiated or emphasized in character imaging. Six methods of emphasis are provided:

- weight;
- posture;
- underlining;
- blinking;
- image inversion;
- crossing-out.

All of these may be controlled by means of rendition selection using the presentation attribute “graphic rendition” and the control function SGR (Select Graphic Rendition).

The emphasis takes effect at the active position of the line box where the control function initiates it and ends at the active position of the line box where the control function specifies an end to the emphasis or at the end of the object.

NOTE 6–10
Not all forms of emphasis allowed by this Standard are applicable to all presentation devices. For example, in printed text, ‘blinking’ may not be able to be represented, a second colour may be an available alternative to ‘faint’ (decreased intensity), but ‘image inversion’ may only be practicable by the use of appropriately designed cameo fonts.

6.1.1 Weight

This provides emphasis or de–emphasis by means of varying the contrast or intensity of the character image.

Using renditions selection, three weights are provided:

- faint (decreased intensity);
- normal intensity (neither faint nor bold);
- bold (increased intensity);

Only one of these may be in effect at any one point in the character stream, so that invoking one resets the others.

6.1.2 Posture

This causes a change of posture between an upright font and an italic font.

Using rendition selection, two renditions are provided:

- not italicised;
- italicised.
Only one of these renditions may be in effect at any one point in the character stream, so that invoking one resets the other.

6.1.3 Underlining
This provides for underlining character images. Three renditions are provided:
- not underlined;
- underlined;
- doubly underlined.
Only one of these renditions may be in effect at any one point in the character stream, so that invoking one resets the others.

NOTE 6–11
For writing systems other than those that use a horizontal writing direction, underlining may be replaced by a suitable emphasis.

6.1.4 Blinking
This provides for flashing of the graphic symbol in the line box ON and OFF. Three renditions are provided:
- steady (not blinking);
- slowly blinking;
- rapidly blinking.
Only one of these renditions may be in effect at any one point in the character stream, so that invoking one resets the other.

NOTE 6–12
Slow blinking should be taken as less than 150 ON/OFF cycles per minute and rapid blinking should be taken as more than 150 per minute.

6.1.5 Image inversion
This causes the colours of the graphic symbol and the line box to be exchanged. Two renditions are provided:
- positive image;
- negative image.
Only one of these renditions may be in effect at any one point in the character stream, so that invoking one resets the other.

NOTE 6–13
Simple inversion of the pels within the line box area may not be sufficient for inverting the character image.

6.1.6 Crossing-out
This allows characters to be marked for deletion. The method of crossing out is not defined but the characters should be legible. Two renditions are provided:
- not crossed-out;
- crossed-out.
Only one of these renditions may be in effect at any one point in the character stream, so that invoking one resets the other.

6.2 Font selection
The capability for font selection is based upon
- font specification: The required fonts and their characteristics must be specified in the document profile (see part 4 of this Standard). There is no limit to the number of fonts that can be specified;
- font designation: A subset of these fonts can be designated for use within a basic component by means of the presentation attribute “character fonts”. This subset is limited to a maximum of 10 fonts;
- font invocation: Any of the fonts within this subset can be invoked by means of the presentation attribute “graphic rendition” and/or control function SGR (Select Graphic Rendition).
6.2.1 **Font specification**

Within the document profile, there is an attribute “fonts list”. This specifies, for each font used in the document:

- a font identifier, represented by an integer, unique within the document;
- a font description consisting of a set of font attributes specifying properties that are common to all characters of the font, e.g. weight, posture, constant or variable spacing, as well as properties that are unique to the individual characters.

The font description includes a structured font name as defined in ISO 9541. The other font attributes allow a recipient to select a suitable substitute font when the font specified by the structured font name is not available.

*NOTE 6–14*

It is necessary to consider that font designs are typically proprietary, and that, in addition, the recipient may have a limited repertoire. Thus, there can be no assurance that a particular font selected by the originator is actually available at the recipient's location, unless the originator has prior knowledge of the facilities available to the recipient. Since this would not generally be true in open interchange, it is necessary to specify the font and character characteristics in a manner that facilitates the selection of a near-equivalent alternative, from the repertoire of fonts available to the recipient.

6.2.2 **Font designation**

The presentation attribute “character fonts” enables a subset of up to 10 fonts from the set of fonts specified in the attribute “fonts list” in the document profile to be designated for use within the basic component.

Each font and its size is specified together with the method of invoking the font, i.e. as the primary or one of the alternative fonts.

If no font is designated for the primary font or for a particular alternative font, it is left to the recipient to select a suitable font for the primary or alternative font concerned.

*NOTE 6–15*

The selection of a substitution font may depend upon the characteristics and capabilities of the presentation device.

6.2.3 **Font invocation**

The control function SGR (Select Graphic Rendition) is used to invoke the primary font or one of the 9 alternative fonts. Such an invocation can be performed anywhere within the content of a basic component.

For the initial conditions at the beginning of the basic component, the font indicated by the presentation attribute “graphic rendition” is invoked. In the absence of this attribute, the primary font is assumed to be invoked. If no fonts have been specified, the font used is implementation dependent.

When a designated font is invoked, any specification of weight or posture by an SGR parameter value, or by the presentation attribute “graphic rendition”, is ignored.

Invocation of a character set by way of code extension does not imply invocation of a font for that character set.

6.3 **Subscript and superscript**

The control functions PLD (Partial Line Down) and PLU (Partial Line Up) provide for characters to be imaged as subscript and superscript respectively.

Finer control of subscript and superscript rendition is provided by the control functions VPB (Line Position Backward) and VPR (Line Position Relative).

6.4 **Character combinations**

Two or more characters can be imaged as if they were a single symbol.

The control function GCC (Graphic Character Composition) within the content identifies the string of characters to be imaged as a single symbol.
7. **DEFINITION OF CHARACTER PRESENTATION ATTRIBUTES**

Presentation attributes are applicable to basic logical and layout components. They specify the initial conditions at the start of the rendition of the content of that basic component. The content architecture associated with each basic component can have the means for changing certain of these presentation attributes by means of control functions embedded in the content; such capabilities are indicated in the definition of each presentation attribute.

The following categories of presentation attributes are defined:

- shared attributes which are available to all character content architecture classes;
- layout attributes which are available to formatted and formatted processable form character content architecture classes;
- logical attributes which are available to processable and formatted processable form character content architecture classes.

These attributes are listed in table 6-1.

For each presentation attribute, a default value is defined. This value is used in the defaulting mechanism as defined in part 2 of this Standard.

This clause also defines values for the content architecture attributes specific to character content architectures. These attributes are defined in part 2 of this Standard.

7.1 Shared presentation attributes

7.1.1 Alignment

CATEGORY: Shared

PERMISSIBLE VALUES: 'start-aligned'
'end-aligned'
'centred'
'justified'

DEFAULT VALUE: 'start-aligned'

DEFINITION:
This attribute specifies the method of character alignment (see 5.2.2).
The character alignment cannot be altered within the content of a basic component. Application
of the value ‘justified’ may be suppressed by an occurrence of the control function JFY (No
Justify).
This attribute can be overridden by the presentation attribute “line layout table” when any
tabulation stops are specified (see 7.1.13).

7.1.2 Character fonts

CATEGORY: Shared

STRUCTURE: 10 pairs of two parameters: font size
font identifier

PERMISSIBLE VALUES: font size: any positive integer
font identifier: any positive integer

DEFAULT VALUES: font size: {none is defined}
font identifier: {none is defined}

DEFINITION:
This attribute designates up to 10 fonts which may be used within the basic component (see 5.1.2
and 6.2). These fonts are referred to as the primary font, the first alternative font, the second
alternative font etc. The fonts designated must be chosen from the fonts listed in the document
profile (see part 4 of this Standard).
The parameter “font size” specifies the size of the font i.e. the height of the character image;
its value is an integer representing the size of the font in SMUs.
The parameter “font identifier” is an integer equal to the font identifier associated with the font
in the document profile attribute “fonts list”.
One of the designated fonts may be invoked at the start of the presentation of the content
associated with a basic component by means of the presentation attribute “graphic rendition”,
otherwise the primary font is assumed to be invoked. Also, fonts may be invoked within the
content by means of the control function SGR (Select Graphic Rendition).

7.1.3 Character orientation

CATEGORY: Shared

PERMISSIBLE VALUES: 0°, 90°, 180°, 270°

DEFAULT VALUE: 0°

DEFINITION:
This attribute specifies the character orientation (see 5.1.3).
The character orientation cannot be altered within the content of a basic component.
7.1.4 Character path

CATEGORY: Shared
PERMISSIBLE VALUES: 0°, 90°, 180°, 270°
DEFAULT VALUE: 0°

DEFINITION:
This attribute specifies the character path (see 5.1.2).
The character path cannot be altered within the content of a basic component. However, local changes of the relationship between the imaging order of the characters and the interchange order can be specified by the control function SRS (Start Reverse String).

7.1.5 Character spacing

CATEGORY: Shared
PERMISSIBLE VALUES: any positive integer
DEFAULT VALUE: the equivalent of 120 BMUs

DEFINITION
This attribute specifies the character spacing which applies at the beginning of the basic component (see 5.1.4).
The value of this attribute is an integer specifying the distance in SMUs.
The character spacing value is only used while a constant spacing font is in use; it has no effect while a variable spacing font is in use.
It can be altered within the content of a basic component by means of the control functions SHS (Select Character Spacing) or SCS (Set Character Spacing).

7.1.6 Code extension announcers

CATEGORY: Shared
PERMISSIBLE VALUES: The value of this attribute consists of the string of escape sequences, in accordance with ISO 2022, to announce the use of code extension features.

DEFAULT VALUE:
The escape sequences announcing the use of the G0 and G2 sets, the G2 set being invoked in columns 10 to 15.

DEFINITION:
This attribute announces the code extension features used in the basic component.
The set of code extension features announced by this attribute cannot be altered within the content of a basic component.

7.1.7 First line offset

CATEGORY: Shared
PERMISSIBLE VALUES: any integer
DEFAULT VALUE: 0

DEFINITION:
This attribute specifies an offset along the character path from the line home position, measured in SMUs (see 5.2.8). The offset may be positive (in the direction of the character path), negative (in the direction opposite to the character path) or zero.
The position identified by application of this offset to the line home position is used instead of the line home position for the purposes of formatting and imaging the first line of the basic layout object in which the content of the basic logical component is laid out.
The value of the presentation attribute "indentation" (see 7.3.1) must be set such that the resulting displacement of the line home position from the start edge of the positioning area is sufficient to enable overhanging characters to be imaged within the positioning area. The first line offset cannot be altered within the content of a basic component.

7.1.8 Graphic character sets
CATEGORY: Shared
PERMISSIBLE VALUES: The value of this attribute consists of the string of escape sequences, in accordance with ISO 2022 and the register of ISO 2375, to designate one or more graphic character sets, and any locking shift functions needed to invoke these character sets.

DEFAULT VALUE:
The escape sequences and shift functions designating and invoking the primary character set of ISO 6937-2 as the G0 set and the supplementary character set of ISO 6937-2 as the G2 set in columns 10 to 15.

DEFINITION:
This attribute specifies the graphic character set(s) designated and/or invoked at the beginning of the basic component.

Other graphic character sets can be designated and/or invoked within the content of a basic component by means of the appropriate code extension escape sequences and shift functions.

7.1.9 Graphic character subrepertoire
CATEGORY: Shared
PERMISSIBLE VALUES: The value of this attribute is either 0 or the identifier of a subrepertoire assigned in the register of ISO 7350. The value 0 identifies the full repertoire of the graphic character sets that are designated at the beginning of the basic component.

DEFAULT VALUE: 0

DEFINITION:
This attribute identifies the subrepertoire of the graphic character repertoire of ISO 6937 used at the beginning of the basic component.

This attribute is only applicable if the graphic character sets of ISO 6937 are used.

Other graphic character subrepertoires can be invoked within the content of a basic component by means of the control function IGS (Identify Graphic Subrepertoire).

7.1.10 Graphic rendition
CATEGORY: Shared
PERMISSIBLE VALUE: A sequence of one or more integers corresponding to parameter values of the control function SGR (Select Graphic Rendition).

DEFAULT VALUE: 0

DEFINITION:
This attribute specifies the rendition parameters for font, underlining, etc. which apply at the beginning of the basic component (see 6.1).

The graphic rendition can be altered within the content of a basic component by means of the control function SGR (Select Graphic Rendition).
NOTE 6–16
If more than one graphic rendition parameter is encoded, then it is the user’s responsibility to ensure that they are consistent.

7.1.11 Itemisation

CATEGORY:

Shared

STRUCTURE:

Three parameters: identifier alignment
identifier start offset
identifier end offset

PERMISSIBLE VALUES:

identifier alignment: ‘no itemisation’
‘start–aligned’
‘end–aligned’
identifier start offset: any integer value
identifier end offset: any integer value

DEFAULT VALUES:

identifier alignment: ‘no itemisation’
identifier start offset: the distance from the line home position to the start of the positioning area
identifier end offset: 0

DEFINITION:

This attribute specifies the placement of an item identifier which may begin the basic component (see 5.2.9).

If the value of the parameter “identifier alignment” is ‘no itemisation’, then no item identifier is present.

For other values of the parameter “identifier alignment”, the parameters “identifier start offset” and “identifier end offset” specify offsets, in SMUs, from the line home position along the character path which identify, respectively, the start edge and end edge of a portion of the line box in which the item identifier will be formatted. These offsets may be positive (in the direction of the character path), negative (in the direction opposite to the character path) or zero.

The item identifier consists of all graphic characters preceding the first occurrence of the control function CR (Carriage Return) in the basic component. The content of the basic component following that CR shall be formatted as specified by the presentation attribute “first line offset”.

Values of the parameter “identifier alignment” other than ‘no itemisation’ specify the method of character alignment for the item identifier.

The value of the presentation attribute “indentation” (see 7.3.1) must be set such that the resulting displacement of the line home position from the start edge of the positioning area is sufficient to enable the item identifier to be imaged within the positioning area. Itemisation cannot be altered within the content of a basic component.

7.1.12 Kerning offset

CATEGORY:

Shared

STRUCTURE:

two parameters: start edge offset
end edge offset

PERMISSIBLE VALUES:

start edge offset: any non-negative integer
end edge offset: any non-negative integer

DEFAULT VALUES:

start edge offset: 0
end edge offset: 0
DEFINITION
This attribute specifies the kerning offset as a pair of integer values in SMUs (see 5.1.6). The parameter “start edge offset” specifies the distance from the edge of the basic layout object to the start edge of the positioning area. The parameter “end edge offset” specifies the distance from the edge of the basic layout object to the end edge of the positioning area. The kerning offset cannot be altered within the content of a basic component.

7.1.13 Line layout table

| CATEGORY: | Shared |
| STRUCTURE: | four parameters: tab reference tab position alignment alignment string |
| PERMISSIBLE VALUES: | tab reference: A string of one to four decimal digits used as the reference parameter in the control function STAB (Selective Tabulation). tab position: any non-negative integer alignment: ‘start–aligned’ ‘end–aligned’ ‘centred’ ‘aligned–around’ alignment string: Graphic characters from the set of graphic elements specified by the presentation attributes “graphic character sets” and “graphic character subrepertoire”. |
| DEFAULT VALUES: | The default values are such that no tabulation stops are defined. |

DEFINITION:
This attribute specifies the positions and types of a sequence of tabulation stops (see 5.2.3). The value of the parameter “tab position” specifies the distance in SMUs, in the direction of the character path, from the start edge of the positioning area to the tabulation stop. When this presentation attribute specifies any tabulation stops, the presentation attribute “alignment” is assumed to have the value ‘start–aligned’ (see 7.1.1). The parameter “alignment string” is only present if the value of the parameter “alignment” is ‘aligned–around’. The tabulation stops cannot be altered within the content of a basic component.

7.1.14 Line progression

| CATEGORY: | Shared |
| PERMISSIBLE VALUES: | 90°, 270° |
| DEFAULT VALUE: | 270° |

DEFINITION:
This attribute specifies the line progression (see 5.1.2). The line progression cannot be altered within the content of a basic component.
7.1.15 Line spacing

CATEGORY: Shared
PERMISSIBLE VALUES: any positive integer
DEFAULT VALUE: the equivalent of 200 BMUs

DEFINITION:
This attribute only applies when proportional line spacing is not to be done by the content layout process. In this case, it specifies the line spacing which applies at the beginning of the basic component (see 5.3).
The value of this attribute is an integer specifying the distance in SMUs.
The line spacing can be altered within the content of a basic component by means of the control functions SVS (Select Line Spacing) or SLS (Set Line Spacing).

7.1.16 Pairwise kerning

CATEGORY: Shared
PERMISSIBLE VALUES: ‘yes’
‘no’
DEFAULT VALUE: ‘no’

DEFINITION:
This attribute specifies whether pairwise kerning should be performed on the content during the formatting process (see 5.2.7).
The value ‘yes’ indicates that the formatting process should perform, if possible, pairwise kerning to the content.
The value ‘no’ specifies that pairwise kerning should not be performed on the content.
The specification of pairwise kerning cannot be altered within the content of a basic component.

7.2 Layout presentation attributes

7.2.1 Formatting indicator

CATEGORY: Layout
PERMISSIBLE VALUES: ‘yes’
‘no’
DEFAULT VALUE: ‘no’

DEFINITION:
This attribute specifies whether the content of a basic component has been formatted by a content layout process or not.
The value ‘yes’ indicates that the content of the basic layout component concerned contains layout control functions representing the effects of any use of the control function STAB (Selective Tabulation) or of the presentation attributes “alignment”, “first line offset”, “itemisation” and/or “pairwise kerning” (see 12.2.1.3.1).
The specification of alignment cannot be altered within the content of a basic component.

NOTE 6–17
In interchange, a recipient can take advantage of this attribute only if he has a character font that is similar to that of the sender, i.e. a font that has the same width for each character as the sender’s font.
7.2.2 Initial offset

CATEGORY: Layout

STRUCTURE: two parameters: horizontal coordinate, vertical coordinate

PERMISSIBLE VALUES: horizontal coordinate: any non-negative integer, vertical coordinate: any non-negative integer

DEFAULT VALUES: The default values of this attribute depend on character path, line progression and line spacing as defined in table 6-2.

Table 6-2 – Default values of the presentation attribute “initial offset”

where

W is the horizontal dimension of basic component
H is the vertical dimension of basic component
S is the backward extent of first line box

DEFINITION:
This attribute specifies the position of the initial point (see 5.3).
The values of the parameters “horizontal coordinate” and “vertical coordinate” specify the horizontal and vertical co-ordinates, in SMUs, of the initial point relative to the top left corner of the basic component. The horizontal coordinate is measured positively from the vertical axis to the right and the vertical coordinate is measured positively from the horizontal axis downwards.
The position of the initial point cannot be altered within the content of a basic component.
7.3 Logical presentation attributes

7.3.1 Indentation

CATEGORY: Logical
PERMISSIBLE VALUES: any non-negative integer
DEFAULT VALUE: 0

DEFINITION:
This attribute specifies the distance, in the direction of character path from the start edge of the positioning area, to the initial point of the basic layout object in which the content of the basic logical component is laid out (see figure 10). The distance is specified in SMUs. The indentation cannot be altered within the content of a basic component.

7.3.2 Orphan size

CATEGORY: Logical
PERMISSIBLE VALUES: any positive integer
DEFAULT VALUE: 1

DEFINITION:
This attribute only applies when the content layout process would result in the basic logical object being laid out in two or more basic layout objects; for example, at a page or frame boundary.
The value of this attribute specifies the minimum number of lines of content that must be placed in the first basic layout object.
If the number of lines remaining in the first basic layout object is less than the value of this attribute, all the content is laid out in subsequent layout objects.
The orphan size cannot be altered within the content of a basic component.

7.3.3 Proportional line spacing

CATEGORY: Logical
PERMISSIBLE VALUES: 'yes'
                    'no'
DEFAULT VALUE:    'no'

DEFINITION
This attribute specifies how the content layout process is to determine the distance between the reference lines of two successive line boxes.
If the value is 'yes', the line spacing is variable and the content layout process takes into account the forward extent of the first line box and the backward extent of the second line box.
If the value is 'no', the line spacing does not depend on the content of the line boxes but is determined from values set by the presentation attribute “line spacing” or the control functions SLS (Set Line Spacing) and SVS (Select Line Spacing).

7.3.4 Widow size

CATEGORY: Logical
PERMISSIBLE VALUES: any positive integer
DEFAULT VALUE: 1
DEFINITION:
This attribute only applies when the content layout process would result in the basic logical object being laid out in two or more basic layout objects; for example, at a page or frame boundary.
The value of this attribute specifies the minimum number of lines of content that must be placed in the last basic layout object.
If the number of lines in the last basic layout object is less than the value of this attribute, sufficient lines shall be moved from the end of the previous basic layout object to meet this requirement.
The widow size cannot be altered within the content of a basic component.
It is possible, e.g. for short basic layout objects, that, in satisfying this requirement and the requirements of the presentation attribute "orphan size", the entire content may be removed from the first basic layout object.

7.4 Content architecture class attributes

7.4.1 Content architecture class
The value of the attribute "content architecture class" of a basic component description that conforms to this part of this Standard is an ASN.1 object identifier with one of the following values:

\{ 2 8 2 6 0 \} for the formatted content architecture class;
\{ 2 8 2 6 1 \} for the processable content architecture class;
\{ 2 8 2 6 2 \} for the formatted processable content architecture class.

7.4.2 Content type
The content architecture class attribute "content type" cannot be used to specify any of the content architecture classes defined in this part of this Standard.

7.5 Interactions between presentation attributes and layout directives
The attribute "concatenation" of the document architecture (see part 2 of this Standard) is applicable to content portions belonging to the same character content architecture class. When concatenation is in effect, as a result of the layout directive "concatenation", then, for the following presentation attributes:
Alignment
Character fonts
Character orientation
Character path
First line offset
Indentation
Itemisation
Kerning offset
Line layout table
Line progression
Orphan size
Pairwise kerning
Widow size
any value that is specified for the first component of the concatenated sequence applies to all components in the sequence.
Thus, in the case of presentation attributes, the values specified for the first component override the values for the other components in the sequence.
8. CHARACTER CONTENT PORTION ATTRIBUTES

8.1 Common coding attributes
The value of the attribute “type of coding” of a content portion description that conforms to this part of this Standard is an ASN.1 object identifier with the value { 2 8 3 6 0 }.

8.2 Other coding attributes
No other coding attributes are defined for content portions conforming to this part of this Standard.

9. FORMAL DEFINITIONS OF CHARACTER CONTENT ARCHITECTURE DEPENDENT DATA TYPES

9.1 Introduction
This clause contains the formal definitions, in ASN.1 notation (defined in ISO 8824), of the data types that are character content architecture dependent.

These data types are

- the data type to represent the character content architecture specific presentation attributes in basic components, presentation styles and default value lists;
- the data type to represent the character content architecture coding attributes in content portions;
- the data type to represent the non-basic values of the character content architecture presentation attributes and control function parameters in the document profile;
- the data type to represent the non-basic values of the character content architecture coding attributes in the document profile;
- the data type to represent the non-standard default values of the character content architecture presentation and coding attributes in the document profile.

9.2 Representation of presentation attributes
The data type “Character–Attributes” contains a set of subordinate data types that specify the character presentation attributes. Some of these subordinate data types are elementary but others are structured and are themselves made up of subordinate data types. The format of these data types is given below.

The subset of subordinate data types that may occur within a particular instance of the data type “Character–Attributes” depends upon the particular character content architecture level that is specified.

Character–Presentation–Attributes (2 8 1 6 2)

DEFINITIONS ::= BEGIN

EXPORTS Character–Attributes,
One–Of–Four–Angles,
One–Of–Two–Angles,
Alignment,
Graphic–Rendition,
Kerning–Offset,
Proportional–Line–Spacing,
Pairwise–Kerning;

Character–Attributes ::= SET { 0 IMPLICIT One–Of–Four–Angles OPTIONAL,
1 IMPLICIT One–Of–Two–Angles OPTIONAL,

10. GRAPHIC CHARACTERS
The set of graphic characters used in the content of a basic component, and their coded representations, are specified by the presentation attributes “graphic character sets” and “graphic character subrepertoire” and the associated control functions, viz. the code extension control functions and the control function IGS (Identify Graphic Subrepertoire) as described below:

- graphic character sets: This presentation attribute specifies the graphic character sets designated and/or invoked at the beginning of the basic component. The specification of the graphic character sets by this attribute implies the definition of a repertoire of graphic characters and of a unique coded representation for each character of that repertoire;

- graphic character subrepertoire: This presentation attribute can be used, when the graphic character sets designated are those of ISO 6937, to restrict the repertoire of graphic characters to a subset of the repertoire implied by the specification of the graphic character sets. Use of this attribute does not affect the coded representations of the graphic characters;

- code extension control functions: These control functions can be used within the content of a basic component to alter the designations and/or invocations of graphic character sets from those specified by the presentation attribute “graphic character sets”;

- IGS (Identify Graphic Subrepertoire): This control function can be used within the content of a basic component, when the graphic character sets designated are those of ISO 6937, to alter the subrepertoire from that specified by the presentation attribute “graphic character subrepertoire”.

When the presentation attributes “graphic character sets” and “graphic character subrepertoire” are not specified for a basic component, their values are determined using the defaulting mechanism defined in part 2 of this Standard, as for any other presentation attribute.

11. DEFINITION OF CONTROL FUNCTIONS AND THE CHARACTER SPACE
Control functions are classified in the following four categories:

- Shared control functions, including code extension control functions, which are available to all classes of character content architecture;

- Layout control functions which are available only to formatted form and formatted processible form character content architectures;

- Logical control functions which are available only to processable form and formatted processible form character content architectures;

- Delimiters which are used to delimit graphic characters and/or shared control functions introduced as a result of a formatting process. The delimiters are available only to formatted processible form character content architectures.

The control functions in these four categories are defined in 11.1 to 11.4 respectively; clause 11.5 defines the character SPACE. The allocation of control functions to categories is summarised in table 6-3.

Control functions that have not been included explicitly in this section are

- The sequence introducers ESC (Escape) and CSI (Control Sequence Introducer) that are permitted to be used in the character content architecture when required to represent a graphic character or a control function;

- Line terminators:

  1) A soft line terminator is represented by the control function CR (Carriage Return) then LF (Line Feed), in that order, where the CR and LF are enclosed between a pair of delimiters SOS (Start Of String) and ST (String Terminator);

  2) A hard line terminator is represented by a control function LF (Line Feed) that immediately follows either a control function CR (Carriage Return) or another LF where the entire sequence of CR and LF(s) is NOT enclosed between a pair of delimiters SOS (Start Of String) and ST (String Terminator).

11.1 Shared control functions

11.1.1 CR – Carriage Return
A control function which causes the active position to be moved to the line home position but not to be moved in the direction of line progression.

*NOTE 6–18*
CR is used in conjunction with the control function LF (Line Feed) to move the active position to the line home position at the beginning of a new line of text. It is also used to move the active position to the line home position, for example, after an item identifier (see 7.1.11). CR should not be used to cause character images to be superimposed.

11.1.2 GCC – Graphic Character Composition
A control function with one parameter which specifies that two or more graphic characters are to be combined into one graphic symbol.

The value of the parameter is 0, 1 or 2.

GCC with the parameter value 0 indicates that the following two graphic characters are to be presented as a single symbol.

GCC with the parameter value 1 indicates the start and GCC with the parameter value 2 indicates the end of a string of graphic characters that are to be presented as a single symbol.

The default value of the parameter is 0.

11.1.3 IGS – Identify Graphic Subrepertoire
A control function with a selective parameter which is used to indicate that a subrepertoire of the graphic character repertoire of ISO 6937 is used in the subsequent text. All graphic character sets that are used to represent the indicated graphic character subrepertoire must be explicitly designated, but need not be invoked, prior to the occurrence of IGS.

The identification of the graphic character subrepertoire may be changed at any point within a document and becomes effective immediately. No graphic characters other than those of the specified subrepertoire shall be used in the text following the occurrence of IGS. The effect of a graphic character subrepertoire identification ceases upon the next occurrence of:

- another IGS;
- the end of the current basic object;
- the designation of any graphic character set.

The default value of the parameter is zero.

A non-zero parameter value is the identifier assigned to a subrepertoire of the repertoire of ISO 6937 in accordance with the registration procedure specified in ISO 7350.

The parameter value zero identifies the entire repertoire of the currently designated graphic character sets.

In the absence of IGS, the subrepertoire identified by the presentation attribute “graphic character subrepertoire” applies or the entire repertoire of the currently designated graphic character sets otherwise.

*NOTE 6–19*
The use of IGS in document application profiles based on this Standard is deprecated. IGS is included in this part of this Standard only for compatibility with some existing applications such as those based upon CCITT Recommendation T.61 (1984).

11.1.4 LF – Line Feed
A control function which causes the active position to be advanced in the direction of line progression but not to be moved in the direction of the character path. The amount of movement is that specified by the most recent occurrence either of the control functions SLS (Set Line Spacing) or SVS (Select Line Spacing) if any, or otherwise by the presentation attribute “line spacing”.

LF is restricted to be used in the following cases:

- at the beginning of the content of a basic layout component;
- immediately following a control function CR (Carriage Return);
- immediately following another LF.

11.1.5 PLD – Partial Line Down
A control function which causes either the start of subscript rendition or the end of superscript rendition of graphic characters.
When superscript rendition is in effect, it is terminated by PLD; otherwise, subscript rendition is initiated by PLD.
Any occurrence of PLD to start subscript rendition shall be followed by a control function PLU (Partial Line Up) in the same line before another PLD or control function LF (Line Feed) is used.
PLD does not affect the position of any (graphic) lines used to implement the graphic rendition ‘underlined’, ‘crossed-out’, or ‘doubly underlined’ when such a graphic rendition is in effect prior to the occurrence of PLD.

NOTE 6–20
The implementation of the subscript rendition initiated by PLD may be accomplished with special character fonts and/or movement of the active position not exceeding a half line space.

NOTE 6–21
The graphic rendition ‘underlined’ may have been effected, prior to the occurrence of PLD, either by the control function SGR (Select Graphic Rendition) or by the non-spacing underline character (see ISO 6937).

11.1.6 PLU – Partial Line Up
A control function which causes either the start of superscript rendition or the end of subscript rendition of graphic characters.
When subscript rendition is in effect, it is terminated by PLU; otherwise, superscript rendition is initiated by PLU.
Any occurrence of PLU to start superscript rendition shall be followed by a control function PLD (Partial Line Down) in the same line before another PLU or control function LF (Line Feed) is used.
PLU does not affect the position of any (graphic) lines used to implement the graphic rendition ‘underlined’, ‘crossed–out’ or ‘doubly underlined’ when such a graphic rendition is in effect prior to the occurrence of PLU.

NOTE 6–22
The implementation of the superscript rendition initiated by PLU may be accomplished with special character fonts and/or movement of the active position not exceeding a half line space.

NOTE 6–23
The graphic rendition ‘underlined’ may have been effected, prior to the occurrence of PLU, either by the control function SGR (Select Graphic Rendition) or by the non-spacing underline character (see ISO 6937).

11.1.7 SCS – Set Character Spacing
A control function with one numeric parameter which specifies the character spacing to be applied to constant spacing fonts in subsequent text.
The specified character spacing takes effect immediately and remains in effect until it is changed by a subsequent occurrence of either SCS or the control function SHS (Select Character Spacing) in the current basic component.
The character spacing is expressed as an integral multiple of SMUs.
The default value of the parameter is the equivalent of 120 BMUs.

11.1.8 SGR – Select Graphic Rendition
A control function with one or more selective parameters which specify one or more graphic rendition aspects for graphic characters and space characters in the subsequent text. The specified graphic rendition(s) takes effect immediately and remains in effect until a subsequent occurrence of SGR in the basic object.
The meaning of the parameter value is shown in table 4.
The default value of the parameter is 0.
Any graphic rendition aspect specified by an occurrence of SGR, with the exceptions as noted in notes 2 and 3 below, is combined with the graphic rendition aspects that are in effect prior to that occurrence of SGR as a result of either an earlier occurrence of SGR or the presentation attribute “graphic rendition” of the current basic object.

When SGR is used to start underlining (singly or doubly), or crossing out, within the scope of subscript or superscript image – see control functions PLD (Partial Line Down) and PLU (Partial Line Up), any lines used to implement such a graphic rendition are lowered or raised in order that the graphic rendition concerned applies to the subscript or superscript characters.

NOTE 6–24
Several parameter values can be used in combination, in order to obtain, for example, underlined italics.

NOTE 6–25
The default parameter value cannot be used in combination with any other parameter value.

NOTE 6–26
When a designated font is invoked, any specification of weight or posture by an SGR parameter value is ignored. This applies to the parameter values 1, 2, 3, 22 and 23. These parameter values are enabled when a primary or alternative font is invoked for which no designation has been made.

NOTE 6–27
The use of parameter values 26 and 50 in document application profiles based on this Standard is deprecated. These values are included in this part of this Standard only for compatibility with some existing applications such as those based upon CCITT Recommendation T.61 (1984).

<td>not variable spacing</td>
</tr>
</tbody>
</table>
11.1.9 SHS – Select Character Spacing
A control function with a selective parameter which specifies the character spacing to be applied to constant spacing fonts in subsequent text.
The specified character spacing remains in effect until it is changed by a subsequent occurrence of either SHS or the control function SCS (Set Character Spacing) in the current basic object.
The meaning of the parameter value is:

<table>
<thead>
<tr>
<th>Value</th>
<th>BMUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>120</td>
</tr>
<tr>
<td>1</td>
<td>100</td>
</tr>
<tr>
<td>2</td>
<td>80</td>
</tr>
<tr>
<td>3</td>
<td>200</td>
</tr>
<tr>
<td>4</td>
<td>400</td>
</tr>
</tbody>
</table>

The default value of the parameter is 0.

11.1.10 SLS – Set Line Spacing
A control function with one numeric parameter which specified the line spacing for subsequent text.
The specified line spacing takes effect immediately and remains in effect until it is changed by a subsequent occurrence of either SLS or the control function SVS (Select Line Spacing) in the current basic component.
The line spacing is expressed as an integral multiple of SMUs.
The default value of the parameter is the equivalent of 200 BMUs.

11.1.11 SRS – Start Reverse String
A control function with one parameter which is used to indicate either the start or end of a string of graphic characters that are to be imaged in the direction opposite to that of the immediately preceding text (see 5.2.4).
SRS with parameter value 1 indicates the start of the string.
SRS with parameter value 0 indicates the end of the string.
Hard and soft line terminators shall not be used between SRS 1 and SRS 0.
Any occurrence of the control functions PLD (Partial Line Down), PLU (Partial Line Up), VPB (Line Position Backward) or VPR (Line Position Relative) within the string of characters delimited by SRS 1 and SRS 0 must be matched by an occurrence of the opposite control function within the string.
Strings delimited by SRS may be nested.

11.1.12 STAB – Selective Tabulation
A control function with a selective parameter which references a tabulation stop position in an associated “line layout table” (see 7.1.13).
This control function specifies the positioning of the subsequent text, until either the occurrence of another STAB or the end of the current line.
This text is to be positioned at the referenced tabulation stop and aligned in accordance with the properties specified for that tabulation stop.
No default value of the parameter is specified.

11.1.13 SUB – Substitute Character
A control function which is used in the place of a character that has been found invalid or in error.

11.1.14 SVS – Select Line Spacing
A control function with a selective parameter which specifies the line spacing for subsequent text. The specified line spacing takes effect immediately and remains in effect until it is changed by a subsequent occurrence of either SVS or the control function SLS (Set Line Spacing) in the current basic object.
The meaning of the parameter value is:

<table>
<thead>
<tr>
<th>Value</th>
<th>BMUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>200</td>
</tr>
<tr>
<td>1</td>
<td>300</td>
</tr>
<tr>
<td>2</td>
<td>400</td>
</tr>
<tr>
<td>3</td>
<td>100</td>
</tr>
<tr>
<td>4</td>
<td>150</td>
</tr>
<tr>
<td>9</td>
<td>600</td>
</tr>
</tbody>
</table>

The default value of the parameter is 0.

11.1.15 VPB – Line Position Backward

A control function with one numeric parameter which causes the active position to be moved in the opposite direction to the line progression the number of SMUs specified by the parameter. The combined effect of all occurrences of the control functions VPB and VPR within a given line must be such that the active position is returned to the reference line before the occurrence of a hard or soft line terminator.

The default value of the parameter is the equivalent of 100 BMUs.

*NOTE 6–28*

The main purposes of VPB are to provide for positioning of parallel annotation and for explicit control for the positioning of superscripts.

11.1.16 VPR – Line Position Relative

A control function with one numeric parameter which causes the active position to be moved in the direction of line progression the number of SMUs specified by the parameter.

The combined effect of all occurrences of the control functions VPB and VPR within a given line must be such that the active position is returned to the reference line before the occurrence of a hard or soft line terminator.

The default value of the parameter is the equivalent of 100 BMUs.

*NOTE 6–29*

The main purposes of VPR are to provide for positioning of parallel annotation and for explicit control for the positioning of subscripts.

11.1.17 Code extension control functions

This is a category of control functions used for the designation and invocation of graphic character sets. They are defined in ISO 6429 and their use is defined in ISO 2022.

11.2 Layout control functions

11.2.1 BS – Backspace

A control function that causes the active position to be moved, in the direction opposite to the character path, a distance specified by the most recent occurrence either of the control functions SHS (Select Character Spacing) or SCS (Set Character Spacing), if any, or otherwise by the presentation attribute “character spacing”.

*NOTE 6–30*

BS allows for the positioning of item identifiers (see other document application profiles based upon this Standard is deprecated. It shall not be used to cause character images to be superimposed.

*NOTE 6–31*

The control function SSW (Set SPACE Width) has no effect on BS.

11.2.2 HPB – Character Position Backward

A control function with one numeric parameter which causes the active position to be moved in the opposite direction to the character path the number of SMUs specified by the parameter. The default value of the parameter is the equivalent of 120 BMUs.

*NOTE 6–32*

The main purposes of HPB are to move the active position backwards from the line home position, and to provide for the positioning of parallel annotation.
11.2.3 HPR – Character Position Relative
A control function with one numeric parameter which causes the active position to be moved in the direction of the character path the number of SMUs specified by the parameter.
The default value of the parameter is the equivalent of 120 BMUs.

NOTE 6-33
Although HPR has a control effect similar to that of one or more space characters, it does not have the graphic equivalence of space characters. Therefore, HPR does not cause spaces to be imaged in accordance with the current graphic rendition, such as underlined, possibly specified by a preceding occurrence of the control function SGR (Select Graphic Rendition).

NOTE 6-34
HPR also provides for the positioning of parallel annotation.

11.2.4 JFY – No Justify
A control function with a selective parameter which is used at the beginning of a line to indicate that the line must not be justified. It has no effect on subsequent lines.
The only parameter value that is permitted to be used is zero, which is also the default parameter value.

11.2.5 SACS – Set Additional Character Separation
A control function with one numeric parameter which specified increased escapement between graphic characters in subsequent text i.e. a positive value for the inter-character space (see 5.2.1).
The specified value applies after the first subsequent graphic character and remains in effect until the next occurrence of SACS or a control function SRCS (Set Reduced Character Separation) or until it is reset to 0 by a subsequent occurrence of a hard or soft line terminator.
The parameter value is expressed in SMUs.
The default value of the parameter is 0.

11.2.6 SRCS – Set Reduced Character Separation
A control function with one numeric parameter which specifies reduced escapement between graphic characters in subsequent text i.e. a negative value for the inter-character space (see 5.2.1).
The specified value applies after the first subsequent graphic character and remains in effect until the next occurrence of SRCS or a control function SACS (Set Additional Character Separation) or until it is reset to 0 by a subsequent occurrence of a hard or soft line terminator.
The parameter value is expressed in SMUs.
The default value of the parameter is 0.

11.2.7 SSW – Set SPACE Width
A control function with one numeric parameter which specifies the character escapement associated with the character SPACE for subsequent text. The specified value takes effect immediately and remains in effect until it is changed by a subsequent occurrence of SSW or reset to the default value by a subsequent occurrence of a hard or soft line terminator.
The parameter value is expressed in SMUs.
No default parameter is specified. The default width of SPACE is equal to the character spacing if the current font has constant spacing and is otherwise determined by the font concerned.

11.3 Logical control functions

11.3.1 BPH – Break Permitted Here
A control function which indicates a point where a line break may occur when text is formatted (see 12.2.1.3.2).
11.3.2 NBH – No Break Here
A control function which indicates a point where no line break must occur when text is formatted (see 12.2.1.3.2).

NOTE 6–35
The graphic character NBSP (No Break Space) should be taken to be equivalent to SPACE followed by NBH.

11.3.3 PTX – Parallel Texts
A control function which delimits passages of text which are interchanged one after the other, but intended to be presented in parallel with one another (see 5.2.5).
The only parameter values permitted are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>end of parallel texts</td>
</tr>
<tr>
<td>1</td>
<td>start of principal text</td>
</tr>
<tr>
<td>3</td>
<td>start of supplementary Japanese Ruby annotation</td>
</tr>
</tbody>
</table>

The default value of the parameter is 0.
PTX with parameter value 1 is the opening delimiter of the first (principal) of two passages of text intended to be presented in parallel with one another.
PTX with parameter value 3 is the closing delimiter of the first passage of text and the opening delimiter of the second (supplementary) passage intended to be presented in parallel with the first.
PTX with parameter value 0 indicates the end of the supplementary passage of text.

NOTE 6–36
Japanese Ruby permits the specification of exactly one supplementary passage of text.

11.4 Delimiters

11.4.1 SOS – Start Of String
A control function that acts as the opening delimited of a string of graphic characters and/or control functions that is marked to facilitate its removal by a subsequent content layout process. The string is closed by the terminating delimited control function ST (String Terminator).

A string thus delimited may contain occurrences of graphic characters and control functions, in particular CR (Carriage Return), LF (Line Feed) and HYPHEN, introduced as a result of a formatting process (see 12.2.1.3).

11.4.2 ST – String Terminator
A control function that acts as the terminating delimiter of a string opened by the delimiter control function SOS (Start Of String).

11.5 SP – Space
A character with properties of both a graphic character and a logical control function.
As a control function, SP is significant to the content layout process. It acts as a word delimiter and indicates a potential line break point except when it is immediately followed by another SP or by an occurrence of the control function NBH (No Break Here) (see 11.3.2).
As a graphic character, SP causes the active position to be advanced without a graphic symbol to be imaged. However, any graphic renditions that are in effect e.g. underlining, also apply to SP.
Any SP(s) that precede a line terminator, and follow the last graphic character of a line, are ignored by the imaging process.
12. **CONTENT LAYOUT PROCESS**

This clause describes a content layout process for basic logical objects associated with content architecture of type character. Its purpose is to aid understanding of the semantics of the presentation attributes and control functions by describing the required results of such a process. However, it is not intended to specify any process that might be carried out in a particular implementation to achieve these results.

12.1 **Introduction**

12.1.1 **Purpose**

The content layout process defines a process of formatting and laying out character content into an allocated area. This area is referred to as the available area and is determined by the document layout process defined in part 2 of this Standard.

The purpose of the content layout process is to convert content associated with basic logical components into content associated with basic layout objects. This might imply a transformation of the content from one form to another.

The content layout process results in the creation of basic layout object(s) into which the content is to be positioned. The dimensions of the basic layout object(s) are returned to the document layout process which determines the precise position of that basic layout object within the available area.

12.1.2 **Available area**

The content layout process is constrained by the available area. That is, the maximum line length is constrained by the dimension of the available area in the direction of the character path. During the layout of the content of a basic logical object into a basic layout object, the following cases can occur:

- the formatted or formatted processable content fits into the available area;
- the formatted or formatted processable content does not fit into the dimension of the available area in the direction of line progression. In this case, an additional or a new available area is required depending upon any constraints imposed by the document layout process;
- the formatted content does not fit into the dimension of the available area in the direction of the character path. In this case, a larger available area is required.

*NOTE 6-37*

This case is most likely to occur when laying out formatted content associated with a basic logical component.

12.1.3 **Presentation attributes**

The content layout process is carried out taking into account the presentation attributes applying to the basic logical object with which the content is associated. The content layout process must also take into account any control functions that are embedded in the content.

The presentation attributes applying to the content layout process can be specified in the generic layout structure and presentation styles. The values of these presentation attributes are determined according to the defaulting rules specified in part 2 of this Standard.

12.1.4 **Character content architecture classes**

The content layout process is described for basic logical objects associated with content that conforms to any of the three character content architecture classes (see 4.1) as follows:

- processable form character content in which the content layout process provides for formatting of the content. The content layout process results in the output of content in formatted or formatted processable form depending upon the desired form of document;
- formatted processable form character content in which the content layout process provides for reformatting of the content. This involves an initialisation process which must be carried out on the content before the content layout process can be applied to that content. The content layout process results in the output of content in formatted or formatted processable form depending upon the desired form of document;
formatted form character content in which the content layout process has no effect on the content itself but still determines the dimensions of the basic layout object into which that content is to be positioned.

12.1.5 **Use of delimiters**

When formatted processable form content is created as a result of the content layout process, all shared control functions and graphic characters inserted into the content as a result of the content layout process are enclosed between the delimiter control functions SOS (Start Of String) and ST (String Terminator).

12.1.6 **Layout of the content**

For each of the three character content architecture classes, three cases of laying out the content of basic logical objects into basic layout objects are possible:

- single basic logical object to single basic layout object: the content of a single basic logical object can be laid out into a single basic layout object and is the only content associated with this basic layout object;
- single basic logical object to multiple basic layout object: the content of a single basic logical object is split among two or more basic layout objects, i.e. the content portions associated with two or more basic layout objects are derived from a single basic logical object;
- multiple basic logical object to single basic layout object: the content of two or more basic logical objects is laid out into a single basic layout object, i.e. the content portions of two or more basic logical objects are associated with a single basic layout object.

Multiple basic logical object to multiple basic layout object is also possible, but not described explicitly since this is a combination of the last two cases above.

12.1.7 **Layout sequence**

In all cases, the same sequence of steps for laying out content associated with a basic logical object is executed as follows:

- initialisation;
- determination of initial point;
- formatting of the content;
- identification of content portions;
- determination of basic layout object dimensions;
- determination of the value of the presentation attribute “initial offset”.

This also results in the creation of a basic layout object.

Although the sequence of steps is the same in all cases, the action performed at individual steps may vary.

12.2 **Content layout process for processable content**

12.2.1 **Single basic logical object to single basic layout object**

12.2.1.1 **Initialisation**

In the case of processable form content, no initialisation of the content is necessary.

12.2.1.2 **Determination of initial point**

The location of the initial point depends upon:

- the presentation attributes “character path” and “line progression” (determining the start edge and top edge of the basic layout object);
- the presentation attribute “kerning offset” (specifying the location of the start edge of the positioning area relative to the start edge of the basic layout object);
- the presentation attribute “indentation” (specifying the distance between the initial point and the start edge of the positioning area);
- the invocation of a font by the presentation attribute “graphic rendition” and the presentation attribute “character orientation” (specifying the minimum backward extent of the first line box);
the presence of control functions PLU (Partial Line Up), PTX (Parallel Texts), VPB (Line Position Backward) and font invocation by SGR (Select Graphic Rendition) in the first line of characters to be imaged (modifying the backward extent of the first line box).

The position of the initial point relative to the start edge and top edge of the positioning area is determined such that:

- its distance from the top edge of the positioning area is equal to the backward extent of the first line box;
- its distance from the start edge of the positioning area is equal to the value specified by the presentation attribute “indentation”.

The position of the initial point relative to the upper left corner of the basic layout object can be determined only after the dimension of the basic layout object has been determined (see 12.2.1.5). This value is assigned to the presentation attribute “initial offset” and should always be specified explicitly in order to achieve the desired result by the content imaging process.

12.2.1.3 Formatting of the content

Formatting of the content involves:

- the positioning of character images within a line box (see 5.2);
- the determination of line breaks;
- the positioning of line boxes within the basic layout object (see 5.3).

It may involve the insertion of control functions and the assignment of presentation attribute values to the basic layout object.

As a general rule, the available area is utilized as much as possible in the direction of the character path.

12.2.1.3.1 Positioning of character images within a line box

There are two sets of operations that have an effect on the positioning of character images within a line box. One of these sets is related to the presentation attribute “formatting indicator”, the other is not.

The operations related to the attribute “formatting indicator” are:

- alignment (presentation attribute “alignment”);
- tabulation (presentation attribute “line layout table” and the control function STAB);
- first line offset (presentation attribute “first line offset”);
- itemisation (presentation attribute “itemisation”);
- pairwise kerning (presentation attribute “pairwise kerning”).

Alignment and tabulation are mutually exclusive but itemisation and first line offset may be applied in combination with either of them.

These operations may be performed by either the content layout process or the content imaging process. However, they can be performed by the content layout process only if the presentation attribute “formatting indicator” and the control functions HPB (Character Position Backward), HPR (Character Position Relative), SACS (Set Additional Character Separation), SRCS (Set Reduced Character Separation) and SSW (Set SPACE Width) are available in the content architecture level concerned.

The result of performing these operations by the content layout process is the insertion of the above control functions in the content.

If the content layout process has performed all of the specified operations for a basic layout object and inserted all necessary control functions, the value of the presentation attribute “formatting indicator” is set to ‘yes’, otherwise it is set to ‘no’.

Whether or not the content layout process inserts these control functions, it always determines the allocation of characters to each line box and the dimensions of each line box.
NOTE 6-38
If the value of the presentation attribute “formatting indicator is ‘no’ or if the font substitution has been made, then the content imaging process should perform these operations.

The other set of operations which are not related to the presentation attribute “formatting indicator” are:

- character ordering (control function SRS);
- parallel annotation (control function PTX);
- graphic character composition (control function GCC).

12.2.1.3.1.1 Pairwise kerning
If the presentation attribute “pairwise kerning” specifies ‘yes’ and the content layout process is capable of performing this function and the font used provides the necessary information, then certain combinations of character images are positioned closer to (or further apart from) each other than determined by their position and escapement points.

When pairwise kerning is performed by the content layout process, it will result in the insertion of control functions HPB (Character Position Backward) or HPR (Character Position Relative) between the two characters involved.

12.2.1.3.1.2 First line offset
The characters associated with the first line can be controlled to be laid out differently from the rest of the lines in this object.

The presentation attribute “first line offset” specifies if the first line has an overhang or indentation relative to the line home position.

When first line offset is performed by the content layout process, it will result in the insertion of a control function HPB (Character Position Backward) or HPR (Character Position Relative).

12.2.1.3.1.3 Itemisation
The first line of a basic layout object may contain an item identifier. The position of the item identifier is controlled by the presentation attribute “itemisation”.

When itemisation is performed by the content layout process, it will result in the insertion of a control function HPB (Character Position Backward) or HPR (Character Position Relative) before the text of the item identifier.

12.2.1.3.1.4 Alignment
None of the alignments except ‘start–aligned’ can be performed until the dimensions of the basic layout object have been determined (see 12.2.1.5).

When alignment is performed by the content layout process, the line length for alignment is determined to be:

- for the first line, the distance between the line home position and the end edge of the positioning area minus the value of the presentation attribute “first line offset”;
- for all other lines, the distance between the line home position and the end edge of the positioning area.

The various values of the presentation attribute “alignment” are treated as follows:

- ‘start–aligned’ does not affect the output of the content layout process;
- ‘end–aligned’ and ‘centred’ result in the insertion of a control function HPR (Character Position Relative) either before the first graphic character of each line or after the CR (Carriage Return) delimiting the item identifier if the presentation attribute “itemisation” specifies a value other than ‘no itemisation’;
- ‘justified’ results in the insertion of zero, one or more control functions SSW (Set SPACE Width), SACS (Set Additional Character Separation) and/or SRCs (Set Reduced Character Separation) in each line which ends with a line terminator inserted by the content layout process. The precise usage of SACS, SRCs and SSW is implementation dependent.
NOTE 6-39
The presentation attribute "alignment" does not apply to the item identifier.
When the presentation attribute "alignment" has the value 'justified', irrespective of whether the alignment is performed by the content layout process or the content imaging process, the control function JFY (No Justify) is inserted at the beginning of the last line of a character sequence in order to avoid justification of this line by the content imaging process.

12.2.1.3.1.5 Tabulation
When tabulation is performed by the content layout process, it results in the insertion of each occurrence of a control function HPR (Character Position Relative) or HPB (Character Position Backward) between each occurrence of the control function STAB (Selective Tabulation) and the first graphic character following it.

12.2.1.3.1.6 Parallel annotation
The occurrence of the control function PTX (Parallel Texts) in the content specifies that a string of characters is to be laid out as a parallel annotation to another specified string of characters. The result of the content layout process is as described in 5.2.5.
If the output of the content layout process is in formatted form, the positioning of the parallel annotation is achieved by the removal of all occurrences of PTX and the insertion of the appropriate control functions HPR (Character Position Relative), HPB (Character Position Backward), VPR (Line Position Relative) and VPB (Line Position Backward).
If the output of the content layout process is in formatted processable form, the positioning of the parallel annotation is achieved by inserting the control functions HPR (Character Position Relative), HPB (Character Position Backward), VPR (Line Position Relative) and VPB (Line Position Backward) and enclosing them by the delimiter control functions SOS (Start Of String) and ST (String Terminator).

12.2.1.3.1.7 Character ordering
The occurrence of the control function SRS (Start Reverse String) in the content of a basic logical object controls the direction of imaging of the interchanged characters. The result of the content layout process is as described in 5.2.4.

12.2.1.3.1.8 Graphic character composition
The control function GCC (Graphic Character Composition) is used to combine two or more graphic characters into a single symbol, the width of which may be less than the sum of the widths of the component characters.

12.2.1.3.2 Insertion of line breaks
The formatting process may cause the insertion of additional line breaks into the content. Existing hard line terminators (CR/LF combinations) that are already in the content remain in the content but must be taken into account during the formatting process.
If the output is in formatted processable form, the inserted line breaks consist of soft line terminators represented by the control function sequence SOS CR LF ST. Optionally, characters inserted by an implementation dependent hyphenation algorithm are included in the SOS–ST string. No characters are deleted from the content.
If the output is in formatted form, the inserted line breaks consist of hard line terminators represented by the control function sequence CR LF. All occurrences of the control functions BPH (Break Permitted Here) and NBH (No Break Here) are deleted.
It is the intention of the formatting process that the number of characters between the inserted line breaks is the maximum possible for each line. The exact algorithm for inserting line breaks is implementation dependent and is not defined in this Standard. However, the line break algorithm shall conform to the following constraints:
- a soft line break may be inserted;
- after a SP which is not immediately followed by another SP or the control function NBH (No Break Here);
- after the control function BPH (Break Permitted Here);
at a point determined by an implementation or language dependent algorithm;
- a line break is not permitted;
- when a subscripted rendition is active;
- within a string with reversed presentation direction;
- within a string of parallel annotation.

12.2.1.3.3 Positioning of line boxes

The first line box is positioned with its line home position at the initial point as described in 12.2.1.2.

Each line box is positioned with its line home position on the line from the initial point in the direction of line progression.

When proportional line spacing is not to be performed, the distance between the line home positions of two successive line boxes is equal to the current line spacing. The initial value of the current line spacing is the value of the presentation attribute “line spacing”. This value may be altered by occurrences of the control function SVS (Select Line Spacing) and SLS (Set Line Spacing).

When proportional line spacing is to be performed by the content layout process, the distance between the line home positions of two successive line boxes is evaluated by an implementation dependent algorithm. If the evaluated distance differs from the current value of line spacing, the control function SLS (Set Line Spacing) is inserted before the line terminator of the first line. The evaluated distance is inserted as the parameter of this control function and also becomes the current line spacing.

If the output of the content layout process is in formatted processable form, those occurrences of the control function SLS (Set Line Spacing) inserted by the content layout process are enclosed by the delimiters SOS (Start Of String) and ST (String Terminator).

12.2.1.4 Identification of content portions

The content layout process shall also provide a value for the attribute “Content portion identifier – layout” for each content portion associated with the layout structure.

12.2.1.5 Determination of object dimensions

The formatting action continues until all the available content has been allocated or all the available area has been filled.

The content layout process attempts to allocate the minimum portion of the available area sufficient to hold all of the available content. Hence, the dimensions of the basic layout object can only be determined once formatted is complete.

The mapping to horizontal and vertical dimensions of the basic layout object is dependent upon the character path as follows:

<table>
<thead>
<tr>
<th>Character path</th>
<th>Dimension in direction of character path</th>
<th>Dimension in direction orthogonal to character path</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 180 90, 270</td>
<td>horizontal dimension vertical dimension</td>
<td>vertical dimension horizontal dimension</td>
</tr>
</tbody>
</table>

12.2.2 Single basic logical object to multiple basic layout objects

If the formatted content does not fit into the available area in the direction of line progression then an additional available area has to be obtained from the document layout process e.g. in the case of a page boundary. In this case, the content of a single basic logical object is allocated to more than one basic layout object. The original content portion is split into several content portions, each corresponding to a different basic layout object.
There are two changes with respect to the description in 12.2.1:
- the presentation attributes of the second and subsequent basic layout object are given values corresponding to the status of rendition (line spacing, character spacing, graphic renditions etc) at the end of the previous basic layout object;
- the allocation of content to basic layout objects is performed such that the presentation attributes “orphan size” and “widow size” are fulfilled.

12.2.3 **Multiple basic logical objects to single basic layout object**

When concatenation results in the content associated with a more than one basic logical object being laid out in a single basic layout object (see 7.5), it may be necessary for the content layout process to insert control functions at the beginning of the second and subsequent basic logical objects so that the values of certain presentation attributes associated with those basic logical objects are applied. These control functions are:
- SHS (Select Character Spacing) or SCS (Set Character Spacing) for “character spacing”;
- Designation and/or invocation sequences for “graphic character sets”;
- IGS (Identify Graphic Subrepertoire) for “graphic character subrepertoire”;
- SGR (Select Graphic Rendition) for “graphic rendition”;
- SVS (Select Line Spacing) or SLS (Set Line Spacing) for “line spacing”.

If the output of the content layout process is in formatted processable form, then the control functions inserted by the content layout process are enclosed by the delimiters SOS (Start Of String) and ST (String Terminator).

The presentation attribute “proportional line spacing” specified for the second or subsequent basic logical objects is interpreted by the content layout process as described in 12.2.1.

The other presentation attributes specified for the second and subsequent basic logical objects are ignored (see 7.5).

12.3 **Content layout process for formatted processable content**

For formatted processable form content, the initialisation step of the content layout process shall
- remove all SOS–ST control strings from the content;
- remove all layout control functions (BS, HPB, HPR, JFY, SACS, SRCS and SSW) from the content (see 11.2);
- combine all content portions associated with the same basic logical object into a single content portion in order to prevent unnecessary fragmentation of the document content which could otherwise occur;
- delete the content portion attribute “content layout identifier – layout”, if present.

After initialisation, the content is in processable form. The remaining steps of the content layout process are as described for processable content (see 12.2).

12.4 **Content layout process for formatted content**

For formatted content, the content layout process still has to determine the dimension of the basic layout object to be allocated.

The same steps of the content layout process are used as for processable form content. In this case, however, formatting only involves
- the positioning of character images within a line box as described in 5.2 and 12.2.1.3.1;
- the positioning of line boxes within a basic layout object as described in 5.3.

13. **CONTENT IMAGING PROCESS**

This clause describes a content imaging process for basic logical objects associated with content architecture of type character.

Its purpose is to aid understanding of the semantics of the presentation attributes and control functions by describing the required results of such a process. However, it is not intended to specify any process that might be carried out in a particular implementation to achieve these results.
13.1 Introduction
The content imaging process is only concerned with the layout structures, the presentation styles and the content of basic layout components conforming to this part of this Standard.
All logical control functions, if any, are ignored.
The content imaging process is only applicable to the formatted and formatted processable form character content architecture classes.

13.2 Content imaging process for formatted content
This subclause describes how the various shared and layout presentation attributes and shared and layout control functions influence the image of the contents.
Most shared presentation attributes and shared control functions serve the purpose of positioning and orienting character images along reference lines and for positioning and orienting these reference lines within the basic layout object.
Thus, the effect of most shared presentation attributes and shared control functions have already been described in the content layout process.
Most layout presentation attributes and control functions are related to positioning and, thus, have already been described as the result of the content layout process.
The following sub-clauses provide additional information relating to the content imaging process.

13.2.1 Determination of initial point
The active position for imaging is set on the initial point within the basic layout object. This information is derived from the presentation attribute “initial offset”.

13.2.2 Choosing character images
The following presentation attributes and control functions determine the character images to be chosen for imaging:
- “graphic character sets” and code extension announcer, designation and invocation control functions;
- “character fonts” (together with the attribute “fonts list” in the document profile);
- “graphic rendition” and SGR (Select Graphic Rendition).
If the specified font is not available, the content imaging process may decide to substitute this font by making use of the font information available in the document profile attribute “fonts list”.

13.2.3 Formatting indicator
The presentation attribute “formatting indicator” specifies whether first line offset, itemisation, alignment, tabulation and pairwise kerning have already been performed by the content layout process or not.
If not, or if the result from the content layout process has been invalidated by a font substitution, then the content imaging process must perform the task in the same way as described in the content layout process (see 12.2.1.3.1).

13.3 Content imaging process for formatted processable content
For content in formatted processable form, the only difference from the case of formatted form is that all logical control functions and the delimiter control functions SOS (Start Of String) and ST (String Terminator) are ignored.
The effect of shared and layout presentation attributes and shared and layout control functions is as described in 13.2.

14. INTERACTIONS BETWEEN PRESENTATION ATTRIBUTES AND CONTROL FUNCTIONS
This clause contains a summary of the interactions among and between presentation attributes and control functions defined in various places in this part of this Standard as follows:
- LF is restricted to be used in the following cases:
  1) at the beginning of the content of a basic layout component;
  2) immediately following a control function CR (Carriage Return);
3) immediately following another LF.
   - BPH or CR is not permitted in the following cases:
     1) when PLU or PLD is active;
     2) after VPR and/or VPB have moved the active position away from the reference line;
     3) between the control functions SRS 1 and SRS 0;
     4) between the control functions PTX 1 and PTX 0.
   - Rendition aspects defined by some presentation attributes can be overridden by control functions embedded in content portions as follows:

<table>
<thead>
<tr>
<th>Presentation attribute</th>
<th>Control function</th>
</tr>
</thead>
<tbody>
<tr>
<td>character spacing</td>
<td>SHS, SCS</td>
</tr>
<tr>
<td>line spacing</td>
<td>SVS, SLS</td>
</tr>
<tr>
<td>graphic rendition</td>
<td>SGR</td>
</tr>
<tr>
<td>graphic character subreperoire</td>
<td>IGS</td>
</tr>
<tr>
<td>graphic character sets</td>
<td>Code extension</td>
</tr>
<tr>
<td></td>
<td>control functions</td>
</tr>
</tbody>
</table>

- When the presentation attribute “line layout table” specifies any tabulation stops, the presentation attribute “alignment” is assumed to have the value “start-aligned”.

15. DEFINITION OF CHARACTER CONTENT ARCHITECTURE CLASSES
This clause defines the three classes of character content architecture as described in clause 5, namely:
   - a formatted form character content architecture which allows for document content to be presented (e.g. printed or displayed) as intended by the originator. Formatted form can be used in any basic component;
   - a processable form character content architecture which allows for document content to be processed (e.g. edited or formatted). Processable form can be used in any basic logical component;
   - a formatted processable form character content architecture which allows for document content to be processed and also to be presented as intended by the originator. Formatted processable form can be used in any basic component.

Subclauses 15.1, 15.2 and 15.3 specify the categories of presentation attributes and control functions that pertain to these content architecture classes. The individual presentation attributes and control functions are summarised in tables 5 and 6. The permissible values and the default values of the presentation attributes and the control functions parameter values are defined in clauses 7 and 11 respectively.

In order to aid the definition of content architecture levels for use in document application profiles (see part 1 of this Standard), the presentation attributes and the control functions that are applicable to each content architecture class are listed in Appendix A, together with their permissible values and default values.

15.1 Formatted character content architecture class
The following categories of presentation attributes and control functions pertain to the formatted character content architecture class:
   - shared presentation attributes (see 7.1);
   - layout presentation attributes (see 7.2);
   - shared control functions (see 11.1);
   - layout control functions (see 11.2).

15.2 Processable character content architecture class
The following categories of presentation attributes and control functions pertain to the processable character content architecture class:
   - shared presentation attributes (see 7.1);
   - logical presentation attributes (see 7.3);
- shared control functions (see 11.1);
- logical control functions (see 11.3).

15.3 Formatted processable character content architecture class

The following categories of presentation attributes and control functions pertain to the formatted processable character content architecture class:
- shared presentation attributes (see 7.1);
- layout presentation attributes (see 7.2);
- logical presentation attributes (see 7.3);
- shared control functions (see 11.1);
- layout control functions (see 11.2);
- logical control functions (see 11.3);
- delimiters (see 11.4).

Appendix A

Presentation Attributes and Control Functions

(This Appendix is not part of the Standard)

This appendix summarizes the presentation attributes and control functions that apply to each of the three content architecture classes (formatted, processable and formatted processable) defined in 15, together with their permissible values and default values.

The purpose of this appendix is to facilitate the definition of content architecture levels for use in document application profiles (see part 1 of this Standard).

A.1 Formatted character content architecture class

A.1.1 Presentation attributes

<table>
<thead>
<tr>
<th>Attribute</th>

</table>

In addition, any code extension control function defined in ISO 2022, within the scope of the value of the attribute “code extension announcers”, is permitted.
Appendix B

Character content architecture levels

(This Appendix is not part of the Standard)

The content of this appendix is for information only and may be included in a future register of character content architecture levels and will then be deleted from this part of this Standard.

This appendix contains the definitions of nine character content architecture levels for use in document application profiles. These have been defined in accordance with the rules contained in part 1 of this Standard.

The content architecture levels defined in this clause are listed below. They are grouped into four formatted content architecture levels (CF), three processable content architecture levels (CP) and two formatted processable content architecture levels (CFP):

- CF-0: This content architecture is functionally equivalent to Telex (CCITT ITA2);
- CF-1: This content architecture is functionally equivalent to conventional implementations of ISO 646;
- CF-2: This content architecture is functionally equivalent to Teletex (CCITT Recommendation T.61);
- CF-3: This content architecture is an enhanced formatted form architecture which does not correspond to any existing standard and which incorporates all the features defined for its class;
- CP-0: This content architecture is functionally equivalent to CCITT Recommendation X.420 (Simple Formattable Documents);
- CP-2: This content architecture is a processable form architecture that functionally corresponds to the formatted content architecture CF-2;
- CP-3: This content architecture is a processable form content architecture which does not correspond to any existing standard and which incorporates all the features defined for its class;
- CFP-2: This content architecture is the formatted processable form architecture which corresponds to the formatted form content architecture CF-2 and the processable form content architecture CP-2;
- CFP-3: This content architecture is a formatted processable form content architecture which does not correspond to any existing standard and which incorporates all the features defined for its class.

CF-0 is a subset of CF-1, which is a subset of CF-2, which in turn is a subset of CF-3.
CP-0 is a subset of CP-2, which in turn is a subset of CP-3.
CF-2 and CP-2 are subsets of CFP-2, which is a subset of CFP-3.
CF-3 and CP-3 are subsets of CFP-3.

B.1 Character content architecture level CF-0

B.1.1 Type

CF-0 is a character content architecture level pertaining to the formatted character content architecture class.

B.1.2 Presentation attributes

None are permitted to be specified. It is assumed that all presentation attributes that are applicable to formatted character content architectures have values equal to the default values specified in part 6 of this Standard except:

- "graphic character set": default value is the primary character set of ISO 6937-2;
- "graphic character subrepertoire": default value is the minimum subrepertoire of ISO 6937-2.
B.1.3 Control functions

<table>
<thead>
<tr>
<th>Control function</th>
<th>Basic value(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>LF</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>SP</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
</tbody>
</table>

B.2 Character content architecture level CF-1

B.2.1 Type
CB-1 is a character content architecture level pertaining to the formatted character content architecture class.

B.2.2 Presentation attributes

<table>
<thead>
<tr>
<th>Presentation attribute</th>
<th>Basic value(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>code extension announcers</td>
<td>any string of escape sequences in accordance with ISO 2022</td>
<td>none</td>
</tr>
<tr>
<td>graphic character sets</td>
<td>the escape sequences to designate, and the locking shift functions to invoke, the primary graphic character set of ISO 6937–2</td>
<td>the escape sequences to designate, and any required locking shift functions to invoke, any other registered graphic character sets</td>
</tr>
<tr>
<td>graphic character subrepertoire</td>
<td>0</td>
<td>the identifier of any registered sub-repertoire of ISO 6937</td>
</tr>
</tbody>
</table>

The default value of these presentation attributes is as specified in part 6 of this Standard. It is assumed that all presentation attributes that are applicable to formatted character content architectures, and that are not specified in the above table, have values equal to the default values specified in part 6 of this Standard.
B.2.3 Control functions

<table>
<thead>
<tr>
<th>Control function</th>
<th>Basic value(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>LF</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>SP</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
</tbody>
</table>

Any code extension control function defined in ISO 2022, within the scope of the value of the attribute “code extension announcers”, is permitted.

B.3 Character content architecture level CF-2

B.3.1 Type
CF-2 is a character content architecture level pertaining to the formatted character content architecture class.

B.3.2 Presentation attributes

<table>
<thead>
<tr>
<th>Presentation attribute</th>
<th>Basic value(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>alignment</td>
<td>start aligned</td>
<td>none</td>
</tr>
<tr>
<td>character orientation</td>
<td>0°</td>
<td>90°</td>
</tr>
<tr>
<td>character path</td>
<td>0°, 90°</td>
<td>270°</td>
</tr>
<tr>
<td>character spacing</td>
<td>the equivalent of 120 BMUs</td>
<td>the equivalent of 80, 100, 120 BMUs</td>
</tr>
<tr>
<td>code extension announcers</td>
<td>any string of escape sequences in accordance with ISO 2022</td>
<td>none</td>
</tr>
<tr>
<td>graphic character sets</td>
<td>the escape sequences to designate, and the locking shift functions to invoke, the graphic character sets of ISO 6937–2</td>
<td>the escape sequences to designate, and any required locking shift functions to invoke, any other registered graphic character sets</td>
</tr>
<tr>
<td>graphic character subrepertoire</td>
<td>3</td>
<td>the identifier of any other registered sub-repertoire of ISO 6937</td>
</tr>
<tr>
<td>graphic rendition</td>
<td>0, 4,</td>
<td>1, 3, 10–19, 22–24, 26,50</td>
</tr>
<tr>
<td>initial offset 1) 2)</td>
<td>any non-negative integer</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>any non-negative integer</td>
<td>none</td>
</tr>
<tr>
<td>Presentation attribute</td>
<td>Basic valu(s)</td>
<td>Non-basic value(s)</td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>line progression</td>
<td>270°</td>
<td>90°</td>
</tr>
<tr>
<td>line spacing</td>
<td>the equivalent of 100, 200, 300, 400 BMUs</td>
<td>the equivalent of 150 BMUs</td>
</tr>
</tbody>
</table>

The default value of these presentation attributes is as specified in part 6 of this Standard except “graphic character subrepertoire”.

It is assumed that all presentation attributes that are applicable to formatted character content architectures, and that are not specified in the above table, have values equal to the default values specified in part 6 of this Standard.

### B.3.3 Control functions

<table>
<thead>
<tr>
<th>Control function</th>
<th>Basic valu(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>BS</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>CR</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>IGS</td>
<td>3</td>
<td>the identifier of any other registered sub-repertoire of ISO 6937</td>
</tr>
<tr>
<td>LF</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>PLD</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>PLU</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>SGR</td>
<td>0, 4</td>
<td>1, 3, 10–19, 22–24, 26, 50</td>
</tr>
<tr>
<td>SHS</td>
<td>0</td>
<td>1, 2, 3</td>
</tr>
<tr>
<td>SP</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>SUB</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>SVS</td>
<td>0, 1, 2, 3</td>
<td>4</td>
</tr>
</tbody>
</table>

Any code extension control function defined in ISO 2022, within the scope of the value of the attribute “code extension announcers”, is permitted.

The default value of these control function parameters is as specified in part 6 of this Standard except IGS (default value = 3).
### B.4 Character content architecture level CF–3

#### B.4.1 Type
CF–3 is a character content architecture level pertaining to the formatted character content architecture class.

#### B.4.2 Presentation attributes

<table>
<thead>
<tr>
<th>Presentation attribute</th>
<th>Basic value(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>
</table>
| alignment                     | start aligned  
end aligned  
centred  
justified |
| character fonts 1)            | none  
2) none |
| character orientation         | $0^\circ$ |
| character path                | $0^\circ$, $90^\circ$ |
| character spacing             | the equivalent of 100  120 BMUs |
| code extension announcers     | any string of escape sequences in accordance with ISO 2022 |
| formatting indicator          | no, yes |
| graphic character sets        | the escape sequences to designate, and the locking shift functions to invoke, the graphic character sets of ISO 6937–2 |
| graphic character subrepertoire | 0 |
| graphic rendition             | 0, 1, 3–4, 9, 10–19, 21–24, 29 |
| first line offset             | any integer |
| initial offset 1)             | any non-negative integer |

<tr>
<td></td>
<td>aligned-around</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>any</td>
<td>none</td>
</tr>
<tr>
<td>line progression 4)</td>
<td>270 degrees</td>
<td>90 degrees</td>
</tr>
<tr>
<td>line spacing</td>
<td>the equivalent of 100, 200, 300, 400 BMUs</td>
<td>any other positive integer</td>
</tr>
<tr>
<td>pairwise kerning</td>
<td>yes, no</td>
<td>none</td>
</tr>
</tbody>
</table>

The default value of these presentation attributes is as specified in part 6 of this Standard.

### B.4.3 Control functions

<table>
<thead>
<tr>
<th>Control function</th>
<th>Basic value(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>BS</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>CR</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>GCC</td>
<td>0, 1, 2</td>
<td>none</td>
</tr>
<tr>
<td>HPB</td>
<td>any positive integer</td>
<td>none</td>
</tr>
<tr>
<td>HPR</td>
<td>any positive integer</td>
<td>none</td>
</tr>
<tr>
<td>IGS</td>
<td>0</td>
<td>none</td>
</tr>
<tr>
<td>JFY</td>
<td>0</td>
<td>the identifier of any registered sub-repertoire of ISO 6937</td>
</tr>
<tr>
<td>LF</td>
<td>not applicable</td>
<td>none</td>
</tr>
<tr>
<td>PLD</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>PLU</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>SACS</td>
<td>any non-negative integer</td>
<td>none</td>
</tr>
<tr>
<td>SCS</td>
<td>any positive integer</td>
<td>none</td>
</tr>
<tr>
<td>SGR</td>
<td>0, 1, 3–4, 9, 10–19, 21–24, 29</td>
<td>2, 5–7, 25–27, 50</td>
</tr>
<tr>
<td>SHS</td>
<td>0, 1</td>
<td>2, 3, 4</td>
</tr>
<tr>
<td>SLS</td>
<td>any positive integer</td>
<td>none</td>
</tr>
<tr>
<td>SP</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>Control function</td>
<td>Basic value(s)</td>
<td>Non-basic value(s)</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>SRCS</td>
<td>any non-negative integer</td>
<td>none</td>
</tr>
<tr>
<td>SRS</td>
<td>0, 1</td>
<td>none</td>
</tr>
<tr>
<td>SSW</td>
<td>any positive integer</td>
<td>none</td>
</tr>
<tr>
<td>STAB</td>
<td>any</td>
<td>none</td>
</tr>
<tr>
<td>SUB</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>SVS</td>
<td>0, 1, 2, 3</td>
<td>4, 9</td>
</tr>
<tr>
<td>VPB</td>
<td>any positive integer</td>
<td>none</td>
</tr>
<tr>
<td>VPR</td>
<td>any positive integer</td>
<td>none</td>
</tr>
</tbody>
</table>

Any code extension control function defined in ISO 2022, within the scope of the value of the attribute “code extension announcers”, is permitted. The default value of these control function parameters is as specified in part 6 of this Standard.

B.5 Character content architecture level CP-0

B.5.1 Type
CP-0 is a character content architecture level pertaining to the processable character content architecture class.

B.5.2 Presentation attributes

<table>
<thead>
<tr>
<th>Presentation attribute</th>
<th>Basic value(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>alignment</td>
<td>start aligned</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>centred</td>
<td></td>
</tr>
<tr>
<td></td>
<td>justified</td>
<td></td>
</tr>
<tr>
<td>code extension</td>
<td>any string of escape sequences in</td>
<td>none</td>
</tr>
<tr>
<td>announcers</td>
<td>accordance with ISO 2022</td>
<td></td>
</tr>
<tr>
<td>graphic rendition</td>
<td>0, 4,</td>
<td>none</td>
</tr>
</tbody>
</table>

The default value of these presentation attributes is as specified in part 6 of this Standard. It is assumed that all presentation attributes that are applicable to processable character content architectures, and that are not specified in the above table, have values equal to the default values specified in part 6 of this Standard except:
- “graphic character subrepertoire”: default value = 3.
### B.5.3 Control functions

<table>
<thead>
<tr>
<th>Control function</th>
<th>Basic value(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>LF</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>SUB</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
</tbody>
</table>

Any code extension control function defined in ISO 2022, within the scope of the value of the attribute “code extension announcers”, is permitted.

### B.6 Character content architecture level CP–2

#### B.6.1 Type

CP–2 is a character content architecture level pertaining to the processable character content architecture class.

#### B.6.2 Presentation attributes

<table>
<thead>
<tr>
<th>Presentation attribute</th>
<th>Basic value(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>alignment</td>
<td>start aligned, end aligned, centred, justified</td>
<td>none</td>
</tr>
<tr>
<td>character orientation</td>
<td>0°</td>
<td>90°</td>
</tr>
<tr>
<td>character path</td>
<td>0°, 90°</td>
<td>270°</td>
</tr>
<tr>
<td>character spacing</td>
<td>the equivalent of 120 BMUs</td>
<td>the equivalent of 80, 100, 200 BMUs</td>
</tr>
<tr>
<td>code extension announcers</td>
<td>any string of escape sequences in accordance with ISO 2022</td>
<td>none</td>
</tr>
<tr>
<td>graphic character sets</td>
<td>the escape sequences to designate, and the locking shift functions to invoke, the graphic character sets of ISO 6937–2</td>
<td>the escape sequences to designate, and any required locking shift functions to invoke, any other registered graphic character sets</td>
</tr>
<tr>
<td>graphic character subrepertoire</td>
<td>3</td>
<td>the identifier of any other registered sub-repertoire of ISO 6937</td>
</tr>
<tr>
<td>graphic rendition</td>
<td>0, 4</td>
<td>1, 3, 10–19, 22–24, 26, 50</td>
</tr>
<tr>
<td>indentation</td>
<td>any non-negative integer</td>
<td>none</td>
</tr>
<tr>
<td>Presentation attribute</td>
<td>Basic value(s)</td>
<td>Non-basic value(s)</td>
</tr>
<tr>
<td>------------------------</td>
<td>----------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>line layout</td>
<td>any</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>any</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>start–aligned</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>end–aligned</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>centred</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>aligned–around</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>any</td>
<td>none</td>
</tr>
<tr>
<td>table</td>
<td>2)</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>3)</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>4)</td>
<td>none</td>
</tr>
<tr>
<td>line progression</td>
<td>270°</td>
<td>none</td>
</tr>
<tr>
<td>line spacing</td>
<td>the equivalent of 100, 200, 300, 400 BMUs</td>
<td>the equivalent of 150 BMUs</td>
</tr>
</tbody>
</table>

The default value of these presentation attributes are as specified in part 6 of this Standard except "graphic character subrepertoire".

It is assumed that all presentation attributes that are applicable to processable character content architectures, and that are not specified in the above table, have values equal to the default values specified in part 6 of this Standard.
### B.6.3 Control functions

<table>
<thead>
<tr>
<th>Control function</th>
<th>Basic value(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>BPH</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>CR</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>IGS</td>
<td>3</td>

<tr>
<td>PLU</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>SGR</td>
<td>0, 4</td>
<td>1, 3, 10–19, 22–24, 26, 50</td>
</tr>
<tr>
<td>SHS</td>
<td>0</td>
<td>1, 2, 3</td>
</tr>
<tr>
<td>SP</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>STAB</td>
<td>any</td>
<td>none</td>
</tr>
<tr>
<td>SUB</td>
<td>not applicable</td>
<td>not applicable</td>
</tr>
<tr>
<td>SVS</td>
<td>0, 1, 2, 3</td>
<td>4, 9</td>
</tr>
</tbody>
</table>

Any code extension control function defined in ISO 2022, within the scope of the value of the attribute “code extension announcers”, is permitted.

The default value of these control function parameters is as specified in part 6 of this Standard except IGS (default value = 3).

### B.7 Character content architecture level CP-3

#### B.7.1 Type
CP-3 is a character content architecture level pertaining to the processable character content architecture class.

#### B.7.2 Presentation attributes

<table>
<thead>
<tr>
<th>Presentation attribute</th>

</tr>
<tr>
<td>VPB</td>
<td>any positive integer</td>
<td>none</td>
</tr>
<tr>
<td>VPR</td>
<td>any positive integer</td>
<td>none</td>
</tr>
</tbody>
</table>

Any code extension control function defined in ISO 2022, within the scope of the value of the attribute “code extension announcers”, is permitted.

The default value of these control function parameters is as specified in part 6 of this Standard.
### B.8 Character content architecture level CFP-2

#### B.8.1 Type

CFP-2 is a character content architecture level pertaining to the formatted processable character content architecture class.

#### B.8.2 Presentation attributes

<table>
<thead>
<tr>
<th>Presentation attribute</th>
<th>Basic value(s)</th>
<th>Non-basic value(s)</th>
</tr>
</thead>

Any code extension control function defined in ISO 2022, within the scope of the value of the attribute "code extension announcers", is permitted.
Appendix C

Coded representations of control functions

(This Appendix is not part of the Standard)

Coded representations of control functions are defined in ISO 6429. A summary of the coded representations of the control functions defined in this part of this Standard is given below.

In this table, CSI denotes the Control Sequence Introducer represented by the bit–combination 09/11 and Pn and Ps denote respectively numeric and selective parameter values represented by one or more bit combinations in the range 03/00 to 03/09.

The coded representation of a control function with parameters but with Pn or Ps omitted represents that control function with the default value of the parameter.

Standard ECMA-101 – Open Document Architecture (ODA) and Interchange Format

Part 7 – Raster Graphics Content Architectures

This second edition of Standard ECMA-101 has been prepared by ECMA/TC29 to align ECMA-101 with the current ISO/CCITT publications.

At present this standard consists of seven parts:
- Part 1, Introduction and General Principles;
- Part 2, Document Structures;
- Part 4, Document Profile;
- Part 5, Open Document Interchange Format (ODIF);
- Part 6, Character Content Architectures;
- Part 7, Raster Graphics Content Architectures;
- Part 8, Geometric Graphics Content Architectures.

At present, there is no part 3.
Further parts may be added to this ECMA Standard.

This part 7 contains three Appendices:
- Appendix A: Summary of Raster Graphics Content Architecture Classes;
- Appendix B: Recommendations for the Development of Raster Graphics Content Architecture Levels in Document Application Profiles;
- Appendix C: Summary of ASN.1 Object Identifiers.
1. SCOPE

The purpose of this ECMA-101 Standard is to facilitate the interchange of documents.

In the context of this Standard, documents are considered to be items such as memoranda, letters, invoices, forms and reports, which may include pictures and tabular material. The content elements used within the documents may include graphic characters, geometric graphics elements and raster graphics elements, all potentially within one document.

NOTE 7–1

This Standard is designed to allow for extensions, including typographical features, colour, spreadsheets and additional types of content such as sound.

This Standard applies to the interchange of documents by means of data communications or the exchange of storage media.

It provides for the interchange of documents for either or both of the following purposes:

- to allow presentation as intended by the originator;
- to allow processing such as editing and reformatting.

The composition of a document in interchange can take several forms:

- formatted form, allowing presentation of the document;
- processable form, allowing processing of the document;
- formatted processable form, allowing both presentation and processing.

This Standard also provides for the interchange of ODA information structures used for the processing of interchanged documents.

Furthermore, this Standard allows for the interchange of documents containing one or more different types of content, such as character text, images, graphics and sound.

This part of ECMA–101 defines:

- the raster graphics content architectures that can be used in conjunction with the document architecture defined in part 2 of this Standard;
- the internal structure of content portions that are structured according to a raster graphics content architecture;
- those aspects of positioning and imaging applicable to the presentation of raster graphics contents in a basic layout object;
- a content layout process which, together with the document layout process defined in part 2 of this Standard, specifies the method for determining the dimensions of basic layout objects for raster graphics content portions;
- the presentation and content portion attributes applicable to raster graphics content architectures.

2. REFERENCES

Part 1 - introduction and general principles;
Part 2 - Document structures;
Part 4 - Document profile;
Part 5 - Open document interchange format (ODIF)

3. DEFINITIONS
For the purpose of this part of this Standard, the definitions given in part 1 apply.

4. GENERAL PRINCIPLES

4.1 Content architectures
This part of this standard defines two classes of raster graphics content architectures:
- Formatted raster graphics content architecture class, which allows for document content to be presented as intended by the originator. Formatted form content can only be associated with basic layout components;
- Formatted processable raster graphics content architecture class, which allows for document content to be processed and also to be presented as intended by the originator. Formatted processable content can be associated with any basic component.

4.1.1 Formatted content architecture class
Formatted raster graphics content is intended to be laid out, or imaged by the recipient in accordance with the originator's intent. It is not intended to be reformatted. This form of content may only be used in formatted form documents.

For this form of content, all the necessary information for positioning of pels has been specified. The method of positioning is specified in clause 5.

A particular feature of this form of content is that the position of the pel array can be offset relative to the position of the basic layout object. As a result, it is possible that not all of the area of the basic layout object is utilised for positioning pels. Also a portion of the pel array may be positioned such that it is outside the basic layout object. Such a portion, if any, is not imaged.

4.1.2 Formatted processable content architecture class
Formatted processable raster graphics content is intended to be laid out, reformatted or imaged by the recipient in accordance with the originator's intent. This form of content may be used in formatted, processable and formatted processable form documents.

The originator may, when using this form of content, specify the precise requirements for the layout and imaging of the pel array. Alternatively, the originator may specify various constraints concerning the intended layout and imaging of the pel array, i.e. the precise requirements are not specified and the layout is determined by the content layout process performed by the recipient.

When the precise requirements for the layout are specified, the fixed dimension layout method is used to layout and image the content. Otherwise, the content is laid out and imaged using the scalable dimension layout method. These layout methods are defined in clause 10.

A particular feature of these layout methods is that in both cases the content is laid out such that the entire basic layout object is utilised. In addition it is possible to specify that only a portion of the pel array is to be laid out.

4.2 Content
The content of a basic component that conforms to a raster graphics content architecture represents a two-dimensional pictorial image in the form of a rectangular two-dimensional array of picture elements (pels).

Each element of the pel array comprises data used to determine the image of the corresponding pel. Each basic component contains exactly one content portion.

The data which determines the image of a pel specifies one of two states, named “set” and “unset”. The set state is used to identify the foreground colour and the unset to identify the background colour. The representation of foreground and background within an image is not defined by this standard.

NOTES 7–2
For reproduction on paper, the background colour will normally be the colour of the paper, for instance white, and the foreground colour a contrasting colour, for instance black.

NOTE 7–3
A future version of this Standard may allow specification of more information for each pel, enabling the representation of multi-colour images.
4.3 Presentation attributes

Presentation attributes are applicable to basic components and specify information for laying out and imaging the content of the basic component, and are defined in clause 6. This information cannot be modified within the content of the basic component to which it applies.

4.4 Content portion attributes

Content portion attributes are applicable to content portions and specify information related to the identification and coding of the content. They are also used in laying out and imaging the content of the content portion. Content portion attributes are defined in clause 7.

4.5 Coding of content information

The methods of encoding the pel array in a content portion structured according to a raster graphics content architecture are specified in clause 9.

4.6 Picture element (pel) array

The picture elements in an array have a defined order. The array consists of an ordered sequence of rows of picture elements. Each row in the array contains the same number of picture elements and consists of an ordered sequence of picture elements that represents a line of the image.

5. PRINCIPLES OF POSITIONING PELS

Two methods of positioning pels within a basic layout object are described in this clause. One of these applies to content portions which pertain to the formatted form content architecture. The other applies to content portions which pertain to the formatted processable form content architecture.

The general principles of positioning that apply to both these methods are described in 5.4.1. Subclauses 5.4.2 and 5.4.3 then describe the specific principles that apply to the formatted and formatted processable forms of content.

A basic logical component with a formatted processable form content architecture class must undergo the content layout process before it can be positioned and imaged. The content layout process (defined in clause 10) determines the block size into which the content portion is to be imaged. The content is then positioned in accordance with the positioning rules for content pertaining to the formatted processable form content architecture class.

Any parts of a raster graphics content portion which extend beyond the boundaries of the basic layout object are not imaged.

5.1 Basic concepts

5.1.1 Measurement units and directions

For raster graphics content, the unit for positioning pels is the Scaled Measurement Unit (SMU). The SMU is derived from the Basic Measurement Unit (BMU) by multiplying the BMU with a factor which is specified by the attribute “unit scaling” (defined in part 4 of this Standard). The BMU and SMU are defined in subclauses 3.3.4.1 and 3.3.4.2 respectively of part 2 of this Standard.

All directions are expressed as counter clockwise angles of rotation relative to some specified reference direction (as illustrated in figure 7-1).
5.1.2 Coordinate systems
Two rectangular coordinate systems are used in the positioning of pels.
One system is a dimensionless coordinate system used to identify the pels that constitute a clipped pel array (defined in 5.3.1). In this system, the origin of the coordinate system is positioned at the first pel in the pel array. One axis is in the direction of the pels in each row of pels. The second axis is in the direction of the columns of pels. This system uses non-negative dimensionless integer values and coordinate pairs are denoted using upper case letters.
The second system is used for the positioning of pels associated with basic layout objects. In this system, one axis is parallel to the horizontal axis of the page coordinate system (defined in part 2 of this Standard) and the other axis is in a direction 270° relative to the horizontal axis. This system uses rational values in scaled measurements units (SMUs) to identify points or specify lengths within a basic layout object. Coordinate pairs are indicated in lower case letters.

5.2 Pel image model
Each pel is associated with a reference area. The side of the reference area along the direction of the pel path equals the pel spacing and the side along the direction of line progression equals the line spacing.
Each reference area has a reference point, which is used for positioning the pel. The reference point is defined as the corner of the reference area situated in the opposite direction of both pel path and line progression. The position of a pel in a basic layout object is defined as the position of reference point of the reference area of that pel.

NOTE 7–4
The position of the image of the pel relative to the reference area is implementation dependent, but it is the intention that the main part of the image of pel is positioned within the reference area.

5.3 Positioning of pels
In general, when positioning (and subsequently imaging) the content of a content portion in relation to a basic layout object, only part of the content is considered. Two methods of selecting the required part of the content are provided:
– specification of a clipped pel array;
– discarding of pels.

5.3.1 The clipped pel array
The clipped pel array is a rectangular array of pels defined by two coordinate pairs in the dimensionless coordinate system. The diagonally opposite pairs of the clipped pel array are identified by the coordinate pairs (X1, Y1) and (X2, Y2) where X1≤X2 and Y1≤Y2. Figure 7–2 illustrates the clipping of a content portion.
5.3.2 Discarded pels

In the formatted raster graphics content architecture class, the number of pels to be discarded at the beginning and the end of each line of pels can be specified by a coding attribute.

5.4 Positioning of pels in a basic layout object

5.4.1 Positioning parameters

The positioning of pels within a basic layout object is determined by the following parameters (illustrated in figure 3):
- initial point;
- pel path;
- line progression;
- pel spacing;
- line spacing.

The values of these parameters remain constant within the content associated with a particular basic layout object.

The general use of these parameters when positioning pels is described below and illustrated in figure 7–3. The particular applicability of these parameters to formatted and formatted processable form content is described in 5.4.2 and 5.4.3 respectively.
Figure 7-3 – Positioning of pels of the clipped pel array within a basic layout object

The initial point is the point relative to which all pels are positioned within a basic layout object. The value of the initial point is a coordinate pair (x,y), where x and y are the horizontal and vertical distances respectively, of the initial point from the reference point of the basic layout object.

The pel path is the direction of progression of successive pels along a line and is expressed as a direction relative to the horizontal axis of the page coordinate system (as defined in part 2 of this Standard).

Line progression is the direction of progression of successive lines and is expressed as a direction relative to the pel path.

Lines of pels are positioned such that the first pel to be positioned on each line falls on an imaginary line through the initial point in the direction of line progression.

The pel spacing is the distance between two adjacent pels along a line, in the direction of the pel path.

The line spacing is the distance between adjacent pels in the direction of line progression. The line spacing may be less than, greater than or equal to the pel spacing.

The spacing ratio is defined as the ratio of the line spacing to pel spacing.

The aspect ratio of a clipped pel array that has been positioned in a basic layout object is defined as the ratio of the dimension of the pel array in the direction of pel path to the dimension in the direction of line progression.

The first pel of the clipped pel array is positioned at the initial point.

Each pel on the first line is positioned along a line through the initial point in the direction of the pel path.

The first pel of each line is positioned along a line through the initial point in the direction of line progression.
5.4.2 Positioning rules for formatted form content

For this form of content, the positioning parameters are explicitly specified by applicable presentation attributes (see clause 6).

It is not possible to define a clipped pel array when using this form of content. However, a coding attribute can be used to indicate that a specified number of pels are to be discarded at the beginning and end of each line of the content portion. In this case, only the remaining pels in the content position are considered for positioning.

The line spacing and pel spacing are both specified by the same presentation attribute, and take the same value from the limited set of values specified in 6.2.2.

The initial point can be positioned anywhere inside or outside of the basic layout object. Its default position (see 6.2.1) is the corner of the basic layout object in the opposite direction of both pel path and line progression.

All the pels within a content portion are to be considered for positioning (apart from any pels that are to be discarded). However, pels that would be positioned outside of the basic layout object are not to be imaged by the imaging process.

5.4.3 Positioning rules for formatted processable content

For this form of content, the positioning parameters are determined from information specified in presentation and coding attributes and from the dimensions of the basic layout object.

The clipped pel array is specified by a presentation attribute, which selects the portion of the content portion to be positioned.

The pel path and line progression are explicitly specified by presentation attributes. The initial point is determined from the pel path and line progression specified, such that it is situated in the corner of the basic layout object in the opposite direction of both pel path and line progression (see table 2); other values for the initial point cannot be specified.

The pel spacing is set to be equal to the dimensions of the basic layout object in the direction of the pel path divided by the number of pels per line in the clipped pel array. Similarly, the line spacing is set to be equal to the dimensions of the basic layout object in the direction of line progression divided by the number of lines in the clipped pel array.

Thus the clipped pel array is positioned within the basic layout object such that the reference areas of all the pels completely fill the basic layout object. None of the pels in the clipped pel array can be positioned outside of the basic layout object.

6. DEFINITION OF RASTER GRAPHICS PRESENTATION ATTRIBUTES

Presentation attributes specify the initial conditions relating to the layout and imaging of the content of a basic component. They may be specified for basic logical and layout components and for presentation styles.

There are three categories of raster graphics presentation attributes:

- Logical presentation attributes which take effect during the content layout process, but are ignored during the content imaging process;
- Layout presentation attributes which take effect during the content imaging process. Their values are generated either by the content layout process, or by a process that creates or edits the content;
- Shared presentation attributes which take effect during either or both the content layout and imaging processes.

These attributes are listed in table 7–1.

For each presentation attribute a default value is defined. This value is used in the defaulting mechanism as defined in part 2 of this Standard.

This clause also defines values for the content architecture attributes specific to raster graphics content architectures. These attributes are defined in part 2 of this Standard.

6.1 Shared presentation attributes

6.1.1 Clipping

**CATEGORY:** Shared

**APPLICABILITY:** Formatted processable content architecture class

**STRUCTURE:**
- First coordinate pair: X coordinate, Y coordinate
- Second coordinate pair: X coordinate, Y coordinate

**PERMISSIBLE VALUES:**
- First coordinate pair: non-negative integer, non-negative integer
- Second coordinate pair: non-negative integer, non-negative integer

**DEFAULT VALUES:**
- First coordinate: (0,0)
- Second coordinate: (N-1,L-1) where:
  - N is the number of pels per line,
  - L is the number of lines

**DEFINITION:**
This attribute determines the subregion of the pel array, as described by the content portion, which is to be considered by the content layout process and the content imaging process.

This attribute consists of two coordinate pairs. The first pair specifies the first pel that is part of the selected array. The second pair specifies the last pel that is part of the selected array.

Each coordinate of the first pair must be less than or equal to the corresponding coordinate of the second pair.

6.1.2 Line progression

**CATEGORY:** Shared

**APPLICABILITY:** Formatted and formatted processable content architecture classes

**PERMISSIBLE VALUES:** 90°, 270°

**DEFAULT VALUE:** 270°

**DEFINITION:**
This attribute specifies the direction of the progression of successive lines, relative to the pel path.
6.1.3 Pel path

**CATEGORY:** Shared

**APPLICABILITY:** Formatted and formatted processable content architecture classes

**PERMISSIBLE VALUES:** 0°, 90°, 180°, 270°

**DEFAULT VALUE:** 0°

**DEFINITION:**
This attribute specifies the direction of the progression of successive pels along a line, relative to the horizontal axis of the basic layout object.

6.2 Layout presentation attributes

6.2.1 Initial offset

**CATEGORY:** Layout

**APPLICABILITY:** Formatted content architecture class

**STRUCTURE:** Two parameters: horizontal coordinate, vertical coordinate

**PERMISSIBLE VALUES:**
- Horizontal coordinate: any integer
- Vertical coordinate: any integer

**DEFAULT VALUES:** The default value of this attribute depends on the pel path and line progression as defined in table 2

**Table 7.2 – Default values of the presentation attribute “Initial offset” (position of initial point)**

<table>
<thead>
<tr>
<th>Pel Line path (degrees)</th>

<td>0</td>
</tr>
<tr>
<td></td>
<td>90</td>
<td>BDH</td>
<td>BDV</td>
</tr>
</tbody>
</table>

**NOTE:** The notation used in this table is

BDV = Vertical dimension of block;

BDH = Horizontal dimension of block.

**DEFINITION:**
This attribute specifies the position of the initial point relative to the basic layout object.
The parameters “horizontal coordinate” and “vertical coordinate” specify the horizontal and vertical coordinates, in SMUs, of the initial point relative to the reference point of the basic layout object. The value of each coordinate may be positive, zero or negative; if either or both coordinates are negative then the initial point will be outside the basic layout object.

**NOTE 7-5**
The facility to specify negative coordinate values for the initial point is intended only for use with content architectures based on CCITT Recommendation T.73, such as RFI (see Appendix B), which provide no other clipping mechanism.
6.2.2 Pel transmission density

CATEGORY: Layout

APPLICABILITY: Formatted content architecture class

PERMISSIBLE VALUES: 1, 2, 3, 4, 5, 6 BMU

DEFAULT VALUE: 6 BMU

DEFINITION:
This attribute specifies a single value for both the pel spacing and line spacing.

*NOTE 7-6*

The correspondence between pel spacing, line spacing and resolution is

<table>
<thead>
<tr>
<th>pel spacing and line spacing in BMU</th>
<th>resolution in number of pels per 1 200 BMU</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

6.3 Logical presentation attributes

6.3.1 Image dimensions

CATEGORY: Logical

APPLICABILITY: Formatted processable content architecture class

STRUCTURE: One of four parameters:

a) “width controlled” with sub-parameters:
   “minimum width”,
   “preferred width”

b) “height controlled” with sub-parameters:
   “minimum height”,
   “preferred height”

c) “area controlled” with sub-parameters:
   “minimum width”,
   “preferred width”,
   “minimum height”,
   “preferred height”,
   “aspect ratio flag”

d) “automatic” with no sub-parameters.

PERMISSIBLE VALUES: “minimum width”: non-negative integer,
   “preferred width”: non-negative integer,
   “minimum height”: non-negative integer,
   “preferred height”: non-negative integer,
   “aspect ratio flag”: ‘fixed’, ‘variable’

   “automatic”: ‘null’

DEFAULT VALUE: “automatic”.

DEFINITION:
This attribute specifies the intended dimensions of the basic layout object that is to contain the clipped pel array.
The values of “minimum width” and “preferred width” specify, respectively, the lower limit and the upper limit of the allowed dimensions of the basic layout object in the direction of the pel path. The value of the “minimum width” shall not to be greater than the value of the “preferred width”.

The values of “minimum height” and “preferred height” specify, respectively, the lower limit and the upper limit of the dimensions of the basic layout object in the direction of the line progression. The value of the “minimum height” shall not to be greater than the value of the “preferred height”.

If either or both of the values of the preferred parameters are specified, the corresponding dimensions of the basic layout object are required to be as close to these values as possible.

If only the range of allowed widths is specified (case a), this attribute specifies that the height shall be such that the aspect ratio of the clipped pel array is maintained.

If only the range of allowed heights is specified (case b), this attribute specifies that the width shall be such that the aspect ratio of the clipped pel array is maintained.

If both the ranges of allowed widths and heights are specified (case c) the value of “aspect ratio flag” determines whether or not the aspect ratio of the clipped pel array shall be maintained during the determination of the dimensions of the basic layout object.

If neither the range of allowed heights nor the range of allowed widths is specified (case d), this attribute specifies that the aspect ratio of the basic layout object shall be the same as the aspect ratio of the clipped pel array, and also that the dimension of the basic layout object in the direction of the pel path shall be equal to the dimension of the available area in that direction. All parameters specifying a width or height are specified in SMUs.

6.3.2 Pel spacing

CATEGORY: Logical

APPLICABILITY: Formatted processable content architecture class

STRUCTURE:

Two parameters: “length” “pel spaces”

or the value: ‘null’

PERMISSIBLE VALUES:

“length”: positive integer

“pel spaces”: positive integer

‘null’

DEFAULT VALUE:

“length::” 4

“pel spaces::” 1

DEFINITION:

This attribute specifies the method for determining the distance between successive pels along a line. The attribute consists of either ‘null’, or the two parameters “length” (with integer value m) and “pel spaces” (with integer value n).

If the attribute takes a value of ‘null’ the scalable dimension content layout method is followed.

If the attribute consists of the two parameters, the ratio of the integers m and n (m/n) specifies the spacing in SMUs between two successive pels, and the fixed dimension content layout method is followed.

NOTE 7–7

The scalable and fixed dimension content layout methods are described in clause 10.
6.3.3 Spacing ratio

CATEGORY: Logical
APPLICABILITY: Formatted processable content architecture class
STRUCTURE: Two parameters: “line spacing value” “pel spacing value”
PERMISSIBLE VALUES: “line spacing value”: positive integer “pel spacing value”: positive integer
DEFAULT VALUE: “line spacing value”: 1 “pel spacing value”: 1

DEFINITION:
This attribute specifies the ratio between the line spacing and the pel spacing of the image represented by the content portion. This ratio is to be observed by the raster graphics content layout process (defined in 10) in determining the block size, and by the imaging process (defined in 11) to avoid image distortion.

The value of this attribute consists of two parameters, the “line spacing value” and the “pel spacing value”, the ratio of which equals the ratio of the line spacing to the pel spacing.

The attribute “spacing ratio” is only applicable when the value of the parameter “aspect ratio flag” in the attribute “image dimensions” is set to ‘fixed’.

6.4 Content architecture class attributes

6.4.1 Content architecture class

The value of the attribute “content architecture class” of a basic component description that conforms to this part of this Standard is an ASN.1 object identifier with one of the following values:
{ 2 8 2 7 0 } for the formatted content architecture class;
{ 2 8 2 7 2 } for the formatted processable content architecture class.

6.4.2 Content type

The formatted content architecture class can be specified by the attribute “content type” with the value 1.

NOTE 7–8
Use of the attribute “content type” as an alternative to use of the content architecture class attribute “content architecture class” is permitted only for compatibility with CCITT Recommendation T.73.

7. DEFINITION OF RASTER GRAPHICS CONTENT PORTION ATTRIBUTES

According to part 2 of this Standard, content portion attributes consist of four categories:
- identification attributes;
- common coding attributes;
- coding attributes;
- content information attributes.

The identification attributes are completely defined in part 2 of this Standard.

The common coding attributes are described in part 2 of this Standard; attribute values that are specific to raster graphics content architectures are specified in 7.1.

Coding attributes are defined in 7.2 and the format of the content information, i.e. the possible values of content information attributes, is specified in 7.3.
7.1 Common coding attributes

7.1.1 Type of coding

CLASSIFICATION: Defaultable
APPLICABILITY: Formatted and formatted processable content architecture class
STRUCTURE: ASN.1 object identifier or non-negative integer
PERMISSIBLE VALUES: ASN.1 object identifier:
\{ 2 8 3 7 0 \} for 'T6 encoding',
\{ 2 8 3 7 1 \} for 'T4 one dimensional encoding',
\{ 2 8 3 7 2 \} for 'T4 two dimensional encoding',
\{ 2 8 3 7 3 \} for 'bitmap encoding'
non-negative integer: 0 for 'T6 encoding'.

DEFAULT VALUE: 'T6 encoding'

DEFINITION:
For the raster graphics content architectures, the possible values of this attribute are
- 'T6 encoding', according to the two dimensional encoding scheme defined in CCITT Recommendation T.6;
- 'T4 one dimensional encoding', according to the one dimensional encoding scheme defined in CCITT Recommendation T.4;
- 'T4 two dimensional encoding', according to the two dimensional encoding scheme defined in CCITT Recommendation T.4;
- 'bitmap encoding'.
An explanation of these coding schemes is given in clause 9.
The value of the attribute "type of coding" of a content portion description, that conforms to this part of this Standard, is an ASN.1 object identifier or an integer.
For bitmap encoding, the relationship between the order of pels and the order of bits within an octet is such that the first pel in the order of bits is allocated to the most significant bit of an octet.

7.2 Coding attributes

These attributes provide information required for encoding and decoding the content information, as well as other information that is intrinsic to the content portion and required by the content layout and imaging processes.

7.2.1 Compression

CLASSIFICATION: Defaultable
APPLICABILITY: Formatted and formatted processable content architecture class
PERMISSIBLE VALUES: 'compressed', 'uncompressed'
DEFAULT VALUE: 'compressed'

DEFINITION:
This attribute indicates if the code extension technique for uncompressed mode is present in the content portion. This attribute can have one of two values:
- 'compressed' indicates that the code extension technique for uncompressed mode is not used;
- 'uncompressed' indicates that the code extension technique for uncompressed mode may be used.
NOTE 7-9
Basic mode (compressed) encoding is used initially for coding all such content portions. The occurrence of the code extension technique for uncompressed mode coding results in subsequent content being coded in uncompressed mode.
This attribute is only applicable if the value of the attribute "type of coding" is 'T6 encoding' or 'T4 two dimensional encoding'.

7.2.2 Number of lines

CLASSIFICATION: Non-mandatory
APPLICABILITY: Formatted processable content architecture class
PERMISSIBLE VALUES: Positive integer
DEFINITION:
This attribute specifies the number of lines of pels within a content portion.

NOTE 7-10
This attribute takes effect during the content layout process.

7.2.3 Number of pels per line

CLASSIFICATION: Defaultable for components of the formatted content architecture class; Mandatory for components of the formatted processable content architecture class.
APPLICABILITY: Formatted and formatted processable content architecture classes
PERMISSIBLE VALUES: Non-negative integer
DEFAULT VALUE:
The default value for components of the formatted content architecture class depends upon the "pel transmission density" as specified in table 7-3.

Table 7–3 – Default value of the presentation attribute “number of pels per line”

<table>
<thead>
<tr>
<th>Pel transmission density (BMU)</th>
<th>Default number of pels per line</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10 368</td>
</tr>
<tr>
<td>2</td>
<td>5 184</td>
</tr>
<tr>
<td>3</td>
<td>3 456</td>
</tr>
<tr>
<td>4</td>
<td>2 592</td>
</tr>
<tr>
<td>5</td>
<td>2 074</td>
</tr>
<tr>
<td>6</td>
<td>1 728</td>
</tr>
</tbody>
</table>

No default value is specified for components of the formatted processable content architecture class.
DEFINITION:
This attribute specifies the number of pels in each line within a content portion.
7.2.4 Number of discarded pels

CLASSIFICATION: Defaultable
APPLICABILITY: Formatted content architecture class
PERMISSIBLE VALUES: on-negative integer
DEFAULT VALUE: If the number of pels per line exceeds the line length, then the default value is half the excess number of discarded pels, otherwise it is 0.

DEFINITION:
This attribute specifies the number of pels that are to be ignored at the beginning of each line within a content portion. The positioning of each line is started from the next pel in the line.

7.3 Content information attributes

7.3.1 Content information
For raster graphics content architectures, the value of this attribute is an octet string representing a pel array encoded according to the value of the attribute “type of coding”.

7.4 Interactions with document architecture attributes
The layout directives “invisibility” and “concatenation” are not taken into account during the layout of raster graphics content associated with a basic logical component.

8. FORMAL DEFINITIONS OF RASTER GRAPHICS CONTENT ARCHITECTURE DEPENDENT DATA TYPES

8.1 Introduction
This clause contains formal definitions in ASN.1 notation (defined in ISO 8824) of the data types corresponding to presentation and coding attributes that are applicable to raster graphics content architectures.
Appendix D contains the SGML representation of the attributes specific to raster graphics content architectures.
These data types are
- the data type to represent raster graphics content architecture specific presentation attributes in basic layout components, presentation styles and default value lists;
- the data type to represent raster graphics content architecture specific coding attributes in content portions;
- the data type to represent non-basic values of raster graphics content architecture presentation attributes in the document profile;
- the data type to represent non-basic values of raster graphics content architecture coding attributes in the document profile;
- the data type to represent non-standard default values of raster graphics content architecture presentation and coding attributes in the document profile.

8.2 Representation of presentation attributes
The data type “Raster–Graphics–Attributes” contains a set of subordinate data types that specify the raster graphics presentation attributes. Some of these subordinate data types are elementary but others are structured and are themselves made up of subordinate data types. The format of these data types is given below.
The subset of subordinate data types that may occur within a particular instance of the data type “Raster–Graphics–Attributes” depends upon the particular raster graphics content architecture level that is specified.
Raster-Gr-Presentation-Attributes \{ 28172 \}

9. CODING SCHEMES

A pel array may be represented within a text unit by means of one of the following encoding schemes:

- Group 4 facsimile encoding scheme;
- Group 3 facsimile encoding schemes;
- bitmap encoding scheme.

9.1 Group 4 facsimile encoding scheme

In this encoding scheme, a pel array is encoded according to CCITT Recommendation T.6. The colours “black” and “white” referred to in this Recommendation should be interpreted as “foreground” and “background”, or “set” and “unset”, respectively.

9.2 Group 3 facsimile encoding schemes

In these encoding schemes, a pel array is encoded according the one or two dimensional encoding schemes defined in CCITT Recommendation T.4. The colours “black” and “white” referred to in this Recommendation should be interpreted as “foreground” and “background”, or “set” and “unset”, respectively.

When using the T.4 one- or two-dimensional encoding scheme, the encoded data belonging to each content portion must be terminated by an RTC (Return to control), the format of which is defined in CCITT Recommendation T.4. If the total number of bits belonging to a content portion is not a multiple of eight (i.e. an integral number of octets), then the RTC must be followed by the minimum number of ‘0’ bits such that the last bit aligns on an octet boundary. In addition, the use of EOL is required to indicate the end of encoding of each line of pels and to make up code words that can be used recursively to encode runs of pels longer than 2 624.

When using the two-dimensional encoding scheme, any number of fill bits and any value of K-parameter may be used without declaration in the coding attributes.

9.3 Bitmap encoding scheme

Each element in a pel array may have one of two distinct states. These are the set state, corresponding to foreground colour and the unset state, corresponding to background colour. For the purpose of representing such an array within a content portion, each pel may be represented by a single bit which has the value ‘0’ or ‘1’ depending on the state of that pel. If the pel has the unset state, the value of the bit is ‘0’; otherwise the value of the bit is ‘1’.
In the bitmap encoding scheme, each row of the resulting array of bits is encoded, within a content portion, by a string of octets. If the number of bits in each row of the pel array is not a multiple of eight, then it is extended by the minimum number of '0' bits such that the last bit aligns on an octet boundary.

When the content portion is decoded, the coding attribute "number of pels per line" is used to determine the number of bits in each line that are significant, the remaining bits being ignored. The relationship between the order of the pels and the order of the bits within an octet is such that the first pel in the order of bits is allocated to the most significant bit of an octet.

*NOTE 7-12*
*This encoding scheme is distinct from the uncompressed mode of the Group 3 and 4 facsimile encoding schemes.*

10. **CONTENT LAYOUT PROCESS**

This clause describes a content layout process for basic logical objects associated with raster graphics content architectures.

Its purpose is to aid understanding of the semantics of the presentation attributes and coding attributes by describing the required results of such a process. However, it is not intended to specify any process that might be carried out in a particular implementation to achieve these results.

10.1 **Introduction**

10.1.1 **Purpose**

The content layout process describes the process of laying out raster graphics content into an allocated area. This area is referred to as the available area and is determined by the document layout process defined in part 2 of this Standard.

The purpose of the content layout process is to convert content associated with basic logical components into content associated with basic layout objects.

The content layout process results in the creation of a basic layout object(s) into which the content is to be positioned. The dimensions of each basic layout object are returned to the document layout process, which determines the precise position of that basic layout object within the available area.

One of two methods can be followed for laying out the content of a basic logical object. These methods are

- the fixed dimension content layout method;
- the scalable dimension content layout method.

The choice of method depends on the particular presentation attributes associated with the basic logical object.

10.1.2 **Available area**

The content layout process is constrained by the available area. The maximum dimensions that a basic layout object can take are constrained by the dimensions of the available area.

During the layout of the content associated with a basic logical object into a basic layout object, the following cases can occur

- the formatted processable content fits into the available area;
- the formatted processable content does not fit into the dimensions of the available area. In this case, a new available area is required.

10.1.3 **Presentation attributes**

The content layout process takes into account the presentation attributes applying to the basic logical object with which the content is associated.

The presentation attributes applying to the content layout process can be specified in the generic layout structure and presentation styles. The values of these presentation attributes are determined according to the defaulting rules specified in part 2 of this Standard.

10.1.4 **Coding attributes**

The content layout process takes into account the coding attributes applying to the content portion.
10.1.5 Raster graphics content architecture classes
The content layout process is only specified for basic logical objects associated with the formatted processable raster graphics content architecture class. The content layout process does not modify the form of the content.

10.1.6 Layout of the content
For the raster graphics formatted processable content architecture class, one case of laying out the content into basic objects is possible:
- single basic logical to single basic layout object: the content of a single basic logical object can be laid out into a single basic layout object and is the only content associated with this basic layout object.

10.2 Notation
The following notation is used in the description of the determination of block dimensions:
BDH = horizontal block dimension.
BDV = vertical block dimension.
NLC = number of lines of the clipped array.
NPC = number of pels per line of the clipped array.
AAH = horizontal dimension of available area.
AAV = vertical dimension of available area.
PS = pel spacing.
SR = spacing ratio.

10.3 The fixed dimension content layout method
If the value of the attribute “pel spacing” is specified as other than ‘null’, the fixed dimension content layout method is followed.

The fixed dimension content layout method creates a block with dimensions that satisfy the values of the following attributes:
- the presentation attributes (defined in clause 6):
  - “clipping”
  - “pel path”
  - “pel spacing”;
  - “spacing ratio”;
- the coding attributes (defined in 7.2):
  - “number of lines”;
  - “number of pels per line”.

The fixed dimension content layout process creates a block of the minimum dimensions that are required to accommodate the clipped pel array in accordance with the pel spacing and line spacing. Note that the pel spacing is explicitly specified by the attribute “pel spacing”, whereas the line spacing is determined from the pel spacing and the attribute “spacing ratio”.

The horizontal and vertical block dimensions are determined, such that the reference areas of all the pels of the clipped pel array completely fill the basic layout object. The block dimensions depend on the pel path, pel spacing, spacing ratio, number of pels per line and number of lines as defined in table 7-4.
In the bitmap encoding scheme, each row of the resulting array of bits is encoded, within a content portion, by a string of octets. If the number of bits in each row of the pel array is not a multiple of eight, then it is extended by the minimum number of '0' bits such that the last bit aligns on an octet boundary.

When the content portion is decoded, the coding attribute “number of pels per line” is used to determine the number of bits in each line that are significant, the remaining bits being ignored.

The relationship between the order of the pels and the order of the bits within an octet is such that the first pel in the order of bits is allocated to the most significant bit of an octet.

*NOTE 7-12*
This encoding scheme is distinct from the uncompressed mode of the Group 3 and 4 facsimile encoding schemes.

10. CONTENT LAYOUT PROCESS

This clause describes a content layout process for basic logical objects associated with raster graphics content architectures.

Its purpose is to aid understanding of the semantics of the presentation attributes and coding attributes by describing the required results of such a process. However, it is not intended to specify any process that might be carried out in a particular implementation to achieve these results.

10.1 Introduction

10.1.1 Purpose

The content layout process describes the process of laying out raster graphics content into an allocated area. This area is referred to as the available area and is determined by the document layout process defined in part 2 of this Standard.

The purpose of the content layout process is to convert content associated with basic logical components into content associated with basic layout objects.

The content layout process results in the creation of a basic layout object(s) into which the content is to be positioned. The dimensions of each basic layout object are returned to the document layout process, which determines the precise position of that basic layout object within the available area.

One of two methods can be followed for laying out the content of a basic logical object. These methods are

- the fixed dimension content layout method;
- the scalable dimension content layout method.

The choice of method depends on the particular presentation attributes associated with the basic logical object.

10.1.2 Available area

The content layout process is constrained by the available area. The maximum dimensions that a basic layout object can take are constrained by the dimensions of the available area.

During the layout of the content associated with a basic logical object into a basic layout object, the following cases can occur

- the formatted processable content fits into the available area;
- the formatted processable content does not fit into the dimensions of the available area. In this case, a new available area is required.

10.1.3 Presentation attributes

The content layout process takes into account the presentation attributes applying to the basic logical object with which the content is associated.

The presentation attributes applying to the content layout process can be specified in the generic layout structure and presentation styles. The values of these presentation attributes are determined according to the defaulting rules specified in part 2 of this Standard.

10.1.4 Coding attributes

The content layout process takes into account the coding attributes applying to the content portion.
10.1.5 Raster graphics content architecture classes
The content layout process is only specified for basic logical objects associated with the formatted processable raster graphics content architecture class. The content layout process does not modify the form of the content.

10.1.6 Layout of the content
For the raster graphics formatted processable content architecture class, one case of laying out the content into basic objects is possible:
- single basic logical to single basic layout object: the content of a single basic logical object can be laid out into a single basic layout object and is the only content associated with this basic layout object.

10.2 Notation
The following notation is used in the description of the determination of block dimensions:
BDH = horizontal block dimension.
BDV = vertical block dimension.
NLC = number of lines of the clipped array.
NPC = number of pels per line of the clipped array.
AAH = horizontal dimension of available area.
AAV = vertical dimension of available area.
PS = pel spacing.
SR = spacing ratio.

10.3 The fixed dimension content layout method
If the value of the attribute "pel spacing" is specified as other than ‘null’, the fixed dimension content layout method is followed.
The fixed dimension content layout method creates a block with dimensions that satisfy the values of the following attributes:
- the presentation attributes (defined in clause 6):
  - "clipping"
  - "pel path"
  - "pel spacing"
  - "spacing ratio"
- the coding attributes (defined in 7.2):
  - "number of lines"
  - "number of pels per line"

The fixed dimension content layout process creates a block of the minimum dimensions that are required to accommodate the clipped pel array in accordance with the pel spacing and line spacing. Note that the pel spacing is explicitly specified by the attribute "pel spacing", whereas the line spacing is determined from the pel spacing and the attribute "spacing ratio".
The horizontal and vertical block dimensions are determined, such that the reference areas of all the pels of the clipped pel array completely fill the basic layout object. The block dimensions depend on the pel path, pel spacing, spacing ratio, number of pels per line and number of lines as defined in table 7-4.
Table 7-4 – Dimensions of basic layout object

<table>
<thead>
<tr>
<th>Pel path (segrees)</th>
<th>Horizontal block dimension (BHDH in SMUs)</th>
<th>Vertical block dimension (BDV in SMUs)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 180</td>
<td>NPC * PS</td>
<td>NLC * PS * SR</td>
</tr>
<tr>
<td>90, 270</td>
<td>NLC * PS * SR</td>
<td>NPC * PS</td>
</tr>
</tbody>
</table>

NOTE – The notation used in this table is described in 10.2.

If one of the following conditions occurs:

BDH > AAH or BDV > AAV

then the block will not fit into the available area. It is then the responsibility of the document layout process to determine whether or not the content layout process is to be repeated for an alternative available area.

10.4 The scalable dimension content layout method

If the value of the attribute “Pel spacing” is specified as ‘null’, the scalable content layout method is followed. In this case the pel spacing will depend upon the value of the attribute “image dimensions” and the available area provided by the document layout process.

The aim of the content layout process for scalable dimension content portions is to lay out the content, within the available area, in a basic layout object with the maximum dimensions possible, considering the image dimensions and the spacing ratio specified.

The block dimensions are determined by

- the presentation attributes values (defined in 6):
  - “clipping”;
  - “pel path”;
  - “image dimensions”;
  - “spacing ratio”;
- the coding attributes (defined in 7.2):
  - “number of lines”;
  - “number of pels per line”.

The scalable dimension content layout method first determines the aspect ratio of the clipped pel array, from the “number of pels per line” and “number of lines”, taking into consideration the “spacing ratio”:

\[
\text{aspect ratio} = \frac{\text{NPC}}{\text{NLC} \times \text{SR}}
\]

Determination of the dimensions of the basic layout object depends on the value of the presentation attribute “image dimensions”. The four possible cases are illustrated in figures 4 to 7, and are described below:

a) The attribute “image dimensions” specifies a value for the parameter “width controlled”. In this case the width of the basic layout object will be within the range specified by the originator. The determination of basic layout dimensions is constrained by the range of allowed widths given by the value of the parameter “width controlled”, the dimensions of the available area and the aspect ratio of the clipped array.

The dimensions of the basic layout object shall be determined such that: the basic layout object fits into the available area; the aspect ratio of the basic layout object is the same as that of the clipped pel array; and the width of the basic layout object has a value that is within the range of allowed widths. Also, the width of the basic layout object is determined such that the deviation from the value of “preferred width”, specified by the parameter “width controlled”, is as small as possible.

b) The presentation attribute “image dimensions” specifies a value for the parameter “height controlled”. In this case the height of the basic layout object will be within the range specified by the originator.
The determination of basic layout object dimensions is constrained by the range of allowed heights given by the value of the parameter “height controlled”, the dimensions of the available area and the aspect ratio of the clipped pel array.

The dimensions of the basic layout object shall be determined such that: the basic layout object fits into the available area; the aspect ratio of the basic layout object is the same as that of the clipped pel array; and the height of the basic layout object has a value that is within the range of allowed heights. Also, the height of the basic layout object is determined such that the deviation from the value of “preferred height”, specified by the parameter “height controlled”, is as small as possible.

c) The attribute “image dimensions” specifies a value for the parameter “area controlled”. In this case the dimensions of the basic layout object will be within the range specified by the originator. In particular, this can be used to ensure the basic layout object will have a fixed size.

The determination of basic layout object dimensions is constrained by the range of allowed heights and widths given by the value of the parameter “area controlled”, the dimensions of the available area and, depending upon the value of the “aspect ratio flag” of the parameter “area controlled”, by the aspect ratio of the clipped pel array.

The dimensions of the basic layout object shall be determined such that: the basic layout object fits into the available area; the width of the basic layout object has a value that is within the range of allowed widths; and the height of the basic layout object has a value that is within the range of allowed heights. If the value of “aspect ratio flag” is “fixed” there is the further constraint to the basic layout object dimensions, that the aspect ratio of the basic layout object must be the same as that of the clipped pel array. Also both the width and height of the basic layout object shall be chosen such, that their deviations from their preferred values, specified by the parameter “area controlled”, are both as small as possible.

d) The attribute “image dimensions” specifies a value for the parameter “automatic”. In this case the dimensions of the basic layout object will be automatically adjusted to the page layout.

The determination of basic layout object dimensions is constrained by the dimensions of the available area and the aspect ratio of the clipped pel array.

The dimensions of the basic layout object have to be determined such that: the basic layout object fits into the available area; the width of the basic layout object is given the same value as the dimension of the available area in the same direction; and the height of the basic layout object is determined such, that the aspect ratio of the basic layout object is the same as that of the clipped pel array.

If the given constraints cannot be met, then the document layout process (defined in part 2 of this Standard) is responsible for determining if the content layout method is to be repeated for an alternative available area.

The dimensions of a basic layout object are restricted to integral multiples of 1 SMU.

11. CONTENT IMAGING PROCESS

This clause describes a content imaging process for basic layout objects associated with raster graphics content architectures.

Its purpose is to aid understanding of the semantics of the shared and layout presentation attributes and coding attributes by describing the required results of such a process. However, it is not intended to specify any process that might be carried out in a particular implementation to achieve these results.

11.1 Introduction

The content imaging process is only concerned with the layout structures, the presentation styles and the content of basic layout components conforming to this part of this Standard.

The content imaging process is applicable to basic layout objects associated with the formatted and formatted processable raster graphics content architecture classes.

11.2 Content imaging process for formatted form

This clause describes how the image of the content is influenced by the various presentation and coding attributes applying to the formatted raster graphics content architecture class.

The array of pels to be imaged consists only of those pels of the interchanged pel array which remain after the pels at the beginning of each line, specified by coding attribute “Number of discarded pels”, have been subtracted. The first pel of this array is positioned at the initial point.

The initial point is determined by the attribute “initial offset”.

Only the pels, which are positioned completely within the basic layout object are imaged.

11.3 Content imaging process for formatted processable form

This clause describes how the image of the content is influenced by the various presentation and coding attributes applying to the formatted processable raster graphics content architecture class.

The clipped pel array is imaged in the basic layout object with the first pel at the initial point.

The initial point is determined by the pel path, line progression and by the dimensions of the basic layout object, as defined in table 7-2.

The pel spacing is defined as the width of the basic layout object divided by the number of pels in a line of the clipped pel array.

The line spacing is defined as the height of the basic layout object divided by the number of lines in the clipped pel array.

12. DEFINITION OF RASTER GRAPHICS CONTENT ARCHITECTURE CLASSES

This clause defines the two classes of raster graphics content architectures described in clause 4:

- Formatted raster graphics content architecture class;
- Formatted processable raster graphics content architecture class.

Tables 7-5 and 7-6 specify the categories of presentation and content portion attributes that pertain to these content architecture classes. Content architecture levels for use in application profiles can be defined from these classes using the rules specified in part 1 of this Standard.
### 12.1 Summary of raster graphic presentation attributes

Table 7-5 contains a list of raster graphics presentation attributes, and identifies, for each content architecture class, those which are defaultable and those which are not applicable.

**Table 7-5 – Raster graphics presentation attributes**

<table>
<thead>
<tr>
<th>Presentation attribute</th>
<th>Content architecture class</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Formatted form</td>

</tr>
</tbody>
</table>

**NOTES**

1. The notation used in this table is:
   - not applicable;
   - D applicable and defaultable;
   - NM applicable and non–mandatory;
   - M applicable and mandatory.

2. This attribute is only applicable if the value of the attribute “type of coding” is ‘T6 encoding’ or ‘T4 two dimensional encoding’.
Appendix A

Summary of raster graphics content architecture classes

(This Appendix is not part of the Standard)

This appendix summarises the presentation attributes and content portion attributes that apply to each of the two content architecture classes (formatted and formatted processable) defined in clause 12, together with their permissible values and default values.

The purpose of this appendix is to facilitate the definition of raster graphic content architecture levels for use in document application profiles (see part 1 of this Standard).

A.1 Formatted raster graphics content architecture class

Content pertaining to the formatted raster graphics content architecture class may only be associated with basic layout components.

A.1.1 Presentation attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Permissible values</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pel path</td>
<td>0°, 90°, 180°, 270°</td>
<td>0°</td>
</tr>
<tr>
<td>Line progression</td>
<td>90°, 270°</td>
<td>270°</td>
</tr>
<tr>
<td>Pel transmission density</td>
<td>6, 5, 4, 3, 2, 1 BMU</td>
<td>6 BMU</td>
</tr>
<tr>
<td>Initial offset</td>
<td>(Any integer, Any integer)</td>
<td>See the note</td>
</tr>
</tbody>
</table>

NOTE – The default value of “initial offset” depends upon the pel path and line progression as defined in table 2.
A.1.2 Content portion attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Permissible values</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of pels per line</td>
<td>Any positive integer</td>
<td>See note 1</td>
</tr>
<tr>
<td>Number of discarded pels</td>
<td>Any non-negative integer</td>
<td>See note 2</td>
</tr>
<tr>
<td>Type of coding</td>
<td>T6 encoding</td>
<td>T6 encoding</td>
</tr>
<tr>
<td>Compression</td>
<td>Compressed, Uncompressed as in T.6</td>
<td>Compressed as in T.6</td>
</tr>
</tbody>
</table>

NOTES
1. The default number of pels per line depends upon the pel transmission density as defined in table 3.
2. If the number of pels per line exceeds the image line length, the default number of discarded pels is half the excess number of pels, otherwise it is zero.

A.2 Formatted processable raster graphics content architecture class

Content pertaining to the formatted processable raster graphics form content architecture class may be associated with basic layout or logical objects.
### A.2.1 Presentation attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Permissible values</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pel path</td>
<td>0°, 90°, 180°, 270°</td>
<td>0°</td>
</tr>
<tr>
<td>Line progression</td>
<td>90°, 270°</td>
<td>270°</td>
</tr>
<tr>
<td>Pel spacing</td>
<td>(Any positive integer, any positive integer) SMU, 'null'</td>
<td>(4,1) SMU</td>
</tr>
<tr>

<td>(Any positive integer, any positive integer)</td>
<td>(1,1)</td>
</tr>
<tr>
<td>Clipping</td>
<td></td>
<td></td>
</tr>
<tr>
<td>First pair</td>
<td>(Any non-negative integer, any non-negative integer)</td>
<td>See note 1</td>
</tr>
<tr>
<td>Second pair</td>
<td>(Any non-negative integer, any non-negative integer)</td>
<td></td>
</tr>
<tr>
<td>Image dimensions</td>
<td></td>
<td>See note 2</td>
</tr>
<tr>
<td>Width controlled</td>
<td></td>
<td>Automatic</td>
</tr>
<tr>
<td>Minimum width</td>
<td>Any non-negative integer</td>
<td></td>
</tr>
<tr>
<td>Preferred width</td>
<td>Any non-negative integer</td>
<td></td>
</tr>
<tr>
<td>Height controlled</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Minimum height</td>
<td>Any non-negative integer</td>
<td></td>
</tr>
<tr>
<td>Preferred height</td>
<td>Any non-negative integer</td>
<td></td>
</tr>
<tr>
<td>Area controlled</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Minimum height</td>
<td>Any non-negative integer</td>
<td></td>
</tr>
<tr>
<td>Preferred height</td>
<td>Any non-negative integer</td>
<td></td>
</tr>
<tr>
<td>Minimum width</td>
<td>Any non-negative integer</td>
<td></td>
</tr>
<tr>
<td>Preferred width</td>
<td>Any non-negative integer</td>
<td></td>
</tr>
<tr>
<td>Aspect ratio flag</td>
<td>Any non-negative integer</td>
<td>Variable, fixed</td>
</tr>
<tr>
<td>Automatic</td>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>

**NOTES**

1. The default value of "clipping" is the first coordinate in the content portion (0,0) and the last coordinate (N-1,L-1), where N is number of pels per line and L is number of lines.

2. Minimum values must not be greater than preferred values.
### Content portion attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Permissible values</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of pels per line</td>
<td>Any positive integer</td>
<td>None</td>
</tr>
<tr>
<td>Number of lines</td>
<td>Any positive integer</td>
<td>None</td>
</tr>
<tr>
<td>Type of coding</td>
<td>Bitmap encoding, T4 encoding (one-dim.), T4 encoding (two-dim.), T6 encoding</td>
<td>T6 encoding</td>
</tr>
<tr>
<td>Compression</td>
<td>Compressed, Uncompressed as in T.6</td>
<td>Compressed as in T.6 See the note</td>
</tr>
</tbody>
</table>

**NOTE** – The attribute "compression" is only applicable if the value of the attribute "type of coding" is 'T6 encoding' or 'T4 two dimensional encoding'.
Appendix B

Recommendations for the development of raster graphics content architecture levels in document application profiles

(This Appendix is not part of the Standard)

This Appendix provides examples of the definition of four raster graphics content architecture levels, in accordance with the rules specified in part 1 of this Standard:

- RF-0 is an example of a content architecture level belonging to the formatted form content architecture class. RF-0 is identical to the content architecture used in the context of the document application profile defined in CCITT Recommendation T.503.

- RF-1 is an example of a content architecture level belonging to the formatted form content architecture class. RF-1 is identical to the content architecture used in the context of the document application profile defined in CCITT Recommendation T.501.

- RP-0 is an example of a content architecture level belonging to the formatted processable content architecture class. Content pertaining to this level may be laid out using the fixed dimension layout method.

- RP-1 is an example of a content architecture level belonging to the formatted processable content architecture class. Content pertaining to this level may be laid out using either the fixed dimension layout method (defined in 10.3) or the scalable dimension layout method (defined in 10.4).

NOTE
The application profile may have to specify additional rules for the use of these content architecture levels in particular applications.
B.1 Raster graphics content architecture level RF-0

RF-0 is a content architecture level derived from the formatted form raster graphics content architecture class.

### B.1.1 Presentation attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Basic values</th>
<th>Non-basic values</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pel path</td>
<td>0°</td>

<td>Standard Default Value</td>
</tr>
<tr>
<td>Number of discarded pels</td>
<td>Any non-negative integer</td>
<td>None</td>
<td>Standard Default Value</td>
</tr>
<tr>
<td>Type of coding</td>
<td>T6 encoding</td>
<td>None</td>
<td>Standard Default Value</td>
</tr>
<tr>
<td>Compression</td>
<td>Compressed as in T.6</td>
<td>Uncompressed as in T.6</td>
<td>Standard Default Value</td>
</tr>
</tbody>
</table>
B.2 Raster graphics content architecture level RF–1

RF–1 is a content architecture level derived from the formatted form raster graphics content architecture class.

B.2.1 Presentation attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Basic values</th>
<th>Non-basic values</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pel path</td>
<td>0°</td>
<td>None</td>
<td>Standard Default Value</td>
</tr>
<tr>
<td>Line progression</td>
<td>270°</td>
<td>None</td>
<td>Standard Default Value</td>
</tr>
<tr>
<td>Pel transmission density</td>
<td>5, 4 BMUs</td>
<td>6, 3, 2, 1 BMUs</td>
<td>None, See the note</td>
</tr>
<tr>
<td>Initial Offset</td>
<td>Any integer</td>
<td>Any integer</td>
<td>None</td>
</tr>
</tbody>
</table>

NOTE – “Pel transmission density” is specified as ‘mandatory’ for raster graphics content architecture level RF1.

B.2.2 Content portion attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Basic values</th>
<th>Non-basic values</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of pels per line</td>
<td>Any positive integer</td>
<td>None</td>
<td>None, See the note</td>
</tr>
<tr>
<td>Type of coding</td>
<td>T6 encoding</td>
<td>None</td>
<td>None, See the note</td>
</tr>
<tr>
<td>Compression</td>
<td>compressed as in T.6</td>
<td>uncompressed as in T.6</td>
<td>Standard Default Value</td>
</tr>
</tbody>
</table>

NOTE – “Number of lines per line” and “type of coding” are specified as ‘mandatory’ for raster graphics content architecture level RF1.
B.3 Raster graphics content architecture level RP-0
RP-0 is a raster graphics content architecture level derived from the formatted processable content architecture class; it is laid out using the fixed dimension method of the processable content layout process.

B.3.1 Presentation attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Basic values</th>
<th>Non-basic values</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pel path</td>
<td>0°, 90°, 180°, 270°</td>

<td></td>
<td>as in T.6</td>
<td>Default Value</td>
</tr>
</tbody>
</table>

**NOTE** – The attribute “compression” is only applicable if the value of the attribute “type of coding” is ‘T6 encoding’ or ‘T4 two dimensional encoding’.

### B.4 Raster graphics content architecture level RP–1

RP–1 is a raster graphics content architecture level derived from the formatted processable raster graphics content architecture class; it is laid out using either the fixed or scalable dimension methods of the processable content layout process (depending upon the value of “pel spacing”).

#### B.4.1 Presentation attributes

Standard ECMA–101 – Open Document Architecture (ODA) and Interchange Format

Part 8 – Geometric Graphics Content Architectures

This second edition of Standard ECMA–101 has been prepared by ECMA/TC29 to align ECMA–101 with the current ISO/CCITT publications.

At present this standard consists of seven parts:
- Part 1, Introduction and General Principles;
- Part 2, Document Structures;
- Part 4, Document Profile;
- Part 5, Open Document Interchange Format (ODIF);
- Part 6, Character Content Architectures;
- Part 7, Raster Graphics Content Architectures;
- Part 8, Geometric Graphics Content Architectures.
At present, there is no part 3.

Further parts may be added to this ECMA Standard.

This part 8 contains three Appendices:
- Appendix A: Summary of ASN.1 Object Identifiers;
- Appendix B: Recommendations for the Development of Geometric Graphics Content Architecture Levels in Document Application Profiles;
- Appendix C: Basic Differences between Character Primitives in the Geometric Graphics and the Content of a Basic Component structured according to the Character Content Architectures defined in Part 6 of this Standard.
1. **SCOPE**

The purpose of this ECMA-101 Standard is to facilitate the interchange of documents.

In the context of this Standard, documents are considered to be items such as memoranda, letters, invoices, forms and reports, which may include pictures and tabular material. The content elements used within the documents may include graphic characters, geometric graphics elements and raster graphics elements, all potentially within one document.

**NOTE 8-1**

*This Standard is designed to allow for extensions, including typographical features, colour, spreadsheets and additional types of content such as sound.*

This Standard applies to the interchange of documents by means of data communication or the exchange of storage media.

It provides for the interchange of documents for either or both of the following purposes:

- to allow presentation as intended by the originator;
- to allow processing such as editing and reformatting.

The composition of a document in interchange can take several forms:

- formatted form, allowing presentation of the document;
- processable form, allowing processing of the document;
- formatted processable form, allowing both presentation and processing.

This Standard also provides for the interchange of ODA information structures used for the processing of interchanged documents.

Furthermore, this Standard allows for the interchange of documents containing one or more different types of content such as character text, images, graphics and sound.

This part of ECMA-101:

- defines a geometric graphics content architecture that can be used in conjunction with the document architecture defined in part 2 of this Standard;
- defines an interface which allows the use of content structured according to ISO 8632 within documents structured according to part 2 of this Standard;
- defines those aspects of positioning and imaging applicable to the presentation of this geometric graphics content architecture in a basic layout object;
- defines the presentation attributes applicable to this geometric graphics content architecture;
- describes a content layout process, which together with the document layout process described in part 2 of this Standard, describes the layout of geometric graphics content in basic layout objects and determines the dimensions of these basic layout objects.

2. **REFERENCES**

ECMA-6, 1983, *ISO 7-bit coded character set for information interchange.*

* Part 1 – Introduction and general principles;
* Part 2 – Document structures;
* Part 5 – Open Document Interchange Format (ODIF).

3. **DEFINITIONS, SYMBOLS, ABBREVIATIONS AND CONVENTIONS**

3.1 **Definitions**

For the purpose of this part of this Standard, the definitions given in part 1 of this Standard apply. In addition, the definitions given in ISO 8632 and ISO 8879 apply to this part of this Standard.
3.2 Symbols, abbreviations and conventions

3.2.1 CGM
This term is used to reference the Computer Graphics Metafile defined in ISO 8632. It is used as a qualifier for terms defined in ISO 8632 (for example, CGM elements).

3.2.2 Individual CGM elements
Throughout this part whenever individual CGM elements are referred to they are written in uppercase; for example, SCALING MODE.

3.2.3 CGM concepts
Whenever the concepts defined in CGM are referred to they are written in mixed upper and lower case as appropriate; for example, Scaling Mode or Virtual Device Coordinates.

3.2.4 Width and height
Width is used throughout this part of this Standard to express the extent of a 2-dimensional area in the direction given by the counter-clockwise rotation from the horizontal direction as specified by the geometric graphics presentation attribute “orientation”.
Height is used throughout this part of this Standard to express the extent of a 2-dimensional area orthogonal to its width.

NOTE 8-2
Width or height are mostly used in combination with a reference to an area; for example, width of the available area.

4. GENERAL PRINCIPLES

4.1 Content architecture classes
This part of this Standard defines one class of geometric graphics content architectures:
- a formatted processable form, which allows for document content to be processed and also to be presented as intended by the originator. Formatted processable form content can be associated with any basic component.

4.2 Content
A content portion that is structured according to a geometric graphics content architecture represents a single pictorial image. The representation is based on the Computer Graphics Metafile (CGM) defined in ISO 8632 (see 7.2).
The GC GM provides a format suitable for the storage, retrieval and interchange of picture description information. The format consists of an ordered set of elements. These elements are split into groups that
- structure the information in the metafile;
- specify the precision of the values used within the metafile;
- control the display of the picture;
- perform basic drawing actions;
- control the attributes of the basic drawing actions;
- provide access to non-standard device capabilities.
ISO 8632 defines the form (syntax) and the functional behaviour (semantics) of these elements.

4.3 Presentation attributes
The geometric graphics content architecture defines geometric graphics presentation attributes applicable to basic layout and basic logical components. The geometric graphics presentation attributes direct the content layout process and specify the initial conditions at the start of the presentation of the content associated with a basic object.
Only the geometric graphics presentation attributes specifying CGM defaults (see 6.1.1) can be overwritten by CGM elements in the content of the basic component to which they apply.
4.4 Coding of content information
The ordered set of elements of the content portion is encoded according to the “binary” encoding defined in ISO 8632–3 and constitutes a complete CGM.

The functionality represented by the geometric graphics presentation attributes specifying CGM defaults (see 6.1.1) and CGM element groups is that defined by ISO 8632–1 and ISO 8632–3, except that
- the defaulting rules are modified (see 10.2.1);
- the CGM shall contain only one picture.

4.5 Layout and imaging of the content
The geometric graphics content architecture describes a content layout process which creates a basic layout object and determines the dimensions of this object into which the content associated with a basic logical object is to be laid out.

It also describes a content imaging process which determines the image of the content.

5. POSITIONING

5.1 Introduction
This clause describes the general principles concerning the positioning of a part of the VDC Space within basic layout objects.

This part is known as the region of interest. It is a rectangular region within the VDC Space, and is defined by two Virtual Device Coordinate pairs termed “first corner” and “second corner”.

NOTE 8–3
The VDC Space is used within ISO 8632 for positioning geometric graphics elements, specifying directions, specifying dimensions etc.

5.2 Measurement units and directions
The positioning of geometric graphics content within a basic layout object is specified with relation to an orthogonal coordinate system. The definition of the region of interest specifies the origin and directions of the axes of the coordinate system, with respect to the basic layout object.

Figure 8–1 illustrates that depending on which coordinates of the VDC Space are referenced by “first corner” and “second corner” the region of interest can affect the orientation of the axes used when imaging the geometric graphics content.

The measurement units of the x– and y–axis of the coordinate system are determined by the relationship of the dimensions of the region of interest to the dimensions of the basic layout object.
Figure 8–1 – Mapping of a virtual image defined in the VDC Space to an output medium (e.g., a softcopy device) using different region of interest specifications.
CGM picture with region of interest \(((1,3), (5,6))\) as normally mapped to an output medium
the dotted line represents the region of interest
the arrows indicate the direction of increasing coordinate values

\[(5,6)\]
\[(1,3)\]

The picture above is imaged into the basic layout object as shown The heavy border represents the boundary of the basic layout object.

**Figure 8–2 – Relationship of region of interest to the basic layout object (right handed axes)**

---

CGM picture with region of interest \(((1,6), (5,3))\) as normally mapped to an output medium
the dotted line represents the region of interest
the arrows indicate the direction of increasing coordinate values

\[(5,3)\]
\[(1,6)\]

The picture above is imaged into the basic layout object as shown The heavy border represents the boundary of the basic layout object.

**Figure 8–3 – Relationship of region of interest to the basic layout object (left handed axes)**
5.3 The relationship between the region of interest and the basic layout object

When imaging geometric graphics content, the geometric graphics presentation attribute “picture orientation” determines the relationship of the “first corner” of the region of interest to the corners of the basic layout object.

The “first corner” of the region of interest is coincident with the corner of the basic layout object defined by the geometric graphics presentation attribute “picture orientation” (for example, the bottom left corner if the presentation attribute “picture orientation” has value '0P', see 6.1.3). The “second corner” of the region of interest is coincident with the diagonally opposite corner of the basic layout object. It is implied that the x-axis of the VDC Space always maps to the direction parallel to the width of the basic layout object. Figures 8–2 and 8–3 illustrate this mapping.

6. DEFINITION OF GEOMETRIC GRAPHICS PRESENTATION ATTRIBUTES

Presentation attributes specify the constraints and initial conditions relating to the layout and imaging of a basic component. They may be specified for basic layout components, presentation styles and default value lists.

The following categories of presentation attributes are defined:

- **logical presentation attributes** which take effect during the content layout process but are ignored during the content imaging process;
- **layout presentation attributes** which take effect during the content imaging process. Their values are either determined by a content layout process or specified by a process that creates or edits the content;
- **shared presentation attributes** which take effect during both the content layout and imaging processes.

The geometric graphics presentation attributes are summarized in table 8–1.

**Table 8–1: Geometric graphics presentation attributes**

</tr>
</tbody>
</table>

For each presentation attribute, a default value is defined. This value is used in the defaulting rules as defined in part 2 of this Standard.

This clause also defines values specific to the geometric graphics content architecture for the content architecture class attributes. These attributes are defined in part 2 of this Standard.

6.1 Shared presentation attributes

6.1.1 Attributes specifying CGM defaults

The following presentation attributes provide information used for the construction and interpretation of the CGM defaults. They provide information used by the layout and imaging processes.
NOTE 8–4

This part of this Standard uses the term “CGM defaults” whenever ISO 8632 uses the term “metafile defaults”. This is intended to indicate the different semantics, in conformance with clause 3.2.1, of “defaults” when used in the context of this Standard (ODA) or ISO 8632 (CGM).

The default values given for the parameters of these presentation attributes have been derived from the defaults of the corresponding CGM elements as given in ISO 8632–1 and ISO 8632–3.

NOTE 8–5

Defaults for parameters specifying Direct Colour Values are given either as “foreground” representing the foreground colour, or “background” representing the background colour. The choice of foreground and background colour is implementation dependent. For reproduction on paper the background colour will normally be the colour of the paper, for instance white, and the foreground colour a contrasting colour, for instance black.

The presentation attribute “geometric graphics encoding annoucer” specifies the encoding of parameters of the remaining CGM defaults attributes and specifies default values for the corresponding CGM elements.

The values of the CGM defaults attributes applicable to a basic object are determined by the defaulting rules defined in part 2 of this Standard.

The value of each parameter of a CGM defaults attribute is:
- the value specified;
- if not specified, the value defined in the specification of the default values for the attribute applicable to this parameter.

This part of this Standard does not contain definitions of parameters of presentation attributes specifying CGM defaults which have the same definitions and semantics as CGM elements or parameters of these CGM elements with corresponding names defined in ISO 8632–1. This clause and its sub-clauses contain definitions of parameters for which the definitions differ from the definitions given in ISO 8632–1 and those parameters which are not defined in ISO 8632–1.

For certain parameters the CGM defines value ranges as being reserved for registration. The meanings of these values will be defined using the established procedures of the ISO International Registration Authority for Graphical Items.

The specification of the parameters of the CGM defaults attributes, their permissible and default values is made in tabular form. Some of these parameters have values composed of several sub-parameters. They are shown indented beyond the parameters using a smaller sized font. The sub-parameters may be further substructured. This is shown by further indentation.

Tables 8–2, 8–3 and 8–4 define the default values for the bundle representations, the pattern representations and colour representations, respectively. These tables are used when determining the default state of the imaging process (see 10.2.1).

</tbody>
</table>

**NOTE** — The permissible values of the parameter are restricted to values which are standardized and registered. Private values are not permitted.

This presentation attribute sets default values used for the presentation of the line primitives in the geometric graphics content portion. It specifies the default values for the Line Width Specification Mode, the Line Bundle Index, the individual CGM line attributes, the line aspect source flags and specifies the default line bundle representations.

The line bundle specifications parameter defines the initial line representations to be used for imaging a basic object. For each unspecified representation the values in table 8–2 apply. This parameter consists of a list of zero, one or more pairs. Each pair consists of
- line bundle index;
- line bundle representation, which supplies values for the bundled CGM line attributes.

NOTE – The permissible values of the parameter are restricted to values which are standardized and registered. Private values are not permitted.

This presentation attribute sets default values used for the rendition of the marker primitives in the geometric graphics content portion. It specifies the default values for the Marker Size Specification Mode, the Marker Bundle Index, the individual CGM marker attributes, the marker aspect source flags and specifies the default marker bundle representations.

The marker bundle specifications parameter defines the initial marker representations to be used for imaging a basic object. For each unspecified representation the values in table 8–2 apply.

This parameter consists of a list of zero, one or more pairs. Each pair consists of
- marker bundle index;
- marker bundle representation, which supplies values for the bundled CGM marker attributes.

</table>

NOTE – The permissible values of the parameter are restricted to values which are standardized and registered. Private values are not permitted.

This presentation attribute sets default values used for the rendition of the text primitives of the geometric graphics content portion. It specifies the default values for the Font List, Character Set List, Character Coding Announcer, the Text Bundle Index, the individual CGM text attributes, the text aspect source flags and specifies the default text bundle representations.

The text bundle specifications parameter defines the initial text representations to be used for imaging a basic object. For each unspecified representation the values in table 8–2 apply. This parameter consists of a list of zero, one or more pairs. Each pair consists of
- text bundle index;
- text bundle representation, which supplies values for the bundled CGM text attributes.

</tr>
</tbody>
</table>

**NOTE** – The permissible values of the parameter are restricted to values which are standardized and registered. Private values are not permitted.
This presentation attribute sets default values used for the presentation of the interior of filled area primitives of a geometric graphics content portion. It specifies the default values for the Fill Bundle Index, the individual CGM filled area attributes, the pattern representations, the filled area aspect source flags and default fill bundle representations, applicable to the interior region of the filled area.

The pattern table specifications parameter is a list which supplies a complete set of values for zero, one or more pattern table entries. For each unspecified pattern table entry the values in table 3 apply.

The fill bundle specifications parameter defines the initial bundle representations to be used for imaging a basic object. For each unspecified representation the values in table 8–2 apply. This parameter consists of a list of zero, one or more pairs. Each pair consists of

- fill bundle index;
- fill bundle representation, which supplies values for the bundled CGM filled area attributes.
### 6.1.1.6  Edge rendition

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Permissible values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edge Width</td>
<td>absolute, scaled</td>
<td>scaled</td>
</tr>
<tr>

<tr>
<td>Edge Bundle Index</td>
<td>any integer &gt; 0</td>
<td>1</td>
</tr>
<tr>
<td>Edge Type</td>
<td>1 through 5 plus any registered line type &gt; 5</td>
<td>1(solid)</td>
</tr>
<tr>
<td>(if scaled)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(if absolute)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Edge Colour</td>
<td>any real ≥ 0.0</td>
<td>0.001 x length of longest side of default VDC Extent</td>
</tr>
<tr>
<td>(if indexed)</td>
<td>any non-negative VDC Value</td>
<td></td>
</tr>
<tr>
<td>(if direct)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>edge aspect source flags</td>
<td></td>
<td></td>
</tr>
<tr>
<td>edge type asf</td>
<td>any integer ≥ 0</td>
<td>1 foreground</td>
</tr>
<tr>
<td>edge width asf</td>
<td>any Direct Colour Value</td>
<td>(individual, individual, individual)</td>
</tr>
<tr>
<td>edge colour asf</td>
<td></td>
<td></td>
</tr>
<tr>
<td>edge bundle specifications</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Edge Bundle Index</td>
<td></td>
<td></td>
</tr>
<tr>
<td>edge bundle representation</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Edge Type</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Edge Width</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(if scaled)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(if absolute)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Edge Colour</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(if indexed)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(if direct)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NOTE – The permissible values of the parameter are restricted to values which are standardized and registered. Private values are not permitted.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This presentation attribute sets default values used for the presentation of the edges of the filled area primitives in the geometric graphics content portion. It specifies the default values for the Edge Width Specification Mode, the Edge Visibility, the Edge Bundle Index, the individual CGM edge attributes, the edge aspect source flags and specifies the default edge bundle representations, applicable to the boundary of the filled area.

The edge bundle specifications parameter defines the initial edge representations to be used for imaging a basic object. For each unspecified representation the values in table 8–2 apply. This parameter consists of a list of zero, one or more pairs. Each pair consists of
- edge bundle index;
- edge bundle representation, which supplies values for the bundled CGM edge attributes.
6.1.1.7 Colour representations

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Permissible values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Background Colour</td>
<td>any Direct Colour Value</td>
<td>background</td>
</tr>
<tr>
<td>colour table specifications</td>
<td>any list containing zero, one or more Colour Table elements</td>
<td>empty list</td>
</tr>
<tr>
<td>starting index</td>
<td>any integer $\geq 0$</td>
<td></td>
</tr>
<tr>
<td>colour list</td>
<td>any list containing one or more Direct Colour Values</td>
<td></td>
</tr>
</tbody>
</table>

This presentation attribute sets the default value for Background Colour and defines the initial colour representations to be used for imaging a basic object. The parameter colour table specifications is a list which supplies a complete set of values for zero, one or more elements each of which supplies a list of Direct Colour Value specifications together with the index of the starting colour table entry for a continuous interval of one or more colour table entries. For each unspecified colour representations the values of table 8–4 apply.

6.1.1.8 Transparency specification

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Permissible values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transparency</td>
<td>off, on</td>
<td>on</td>
</tr>
<tr>
<td>Auxiliary Colour</td>
<td>any integer $\geq 0$</td>
<td>0 background</td>
</tr>
<tr>
<td>(if indexed)</td>
<td>any Direct Colour Value</td>
<td></td>
</tr>
<tr>
<td>(if direct)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This presentation attribute sets the default values for Transparency and Auxiliary Colour.

NOTES 8–6
The default values of AUXILIARY COLOUR given in ISO 8632–1 and ISO 8632–3 are inconsistent. Due to these inconsistencies an arbitrary choice of ‘background’ was made.

NOTE 8–7
Auxiliary Colour as defined in ISO 8632 is intended to address hardware features commonly available in raster devices. Some devices may have no such capabilities, or may have a subset of these capabilities to which this parameter pertains. Simulations of such a feature may be very complex. ISO 8632 does not require that a CGM interpreter need simulate the feature when it is not available in the hardware or firmware.
### 6.1.9 Transformation specification

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Permissible values</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>VDC Extent</td>
<td>any pair of Virtual Device Coordinates defining a rectangle</td>
<td>(0;0), (1;1)</td>
</tr>
<tr>
<td>Clip Rectangle</td>
<td>any pair of Virtual Device Coordinates defining a rectangle</td>
<td>same as VDC Extent</td>
</tr>
<tr>
<td>Clip Indicator</td>
<td>off, on</td>
<td>on</td>
</tr>
</tbody>
</table>

This presentation attribute sets the default values for VDC Extent, Clip Rectangle and Clip Indicator.

The Virtual Device Coordinate (0;0) is the symbolic value of the origin of the coordinate system of the VDC Space. The Virtual Device Coordinate (1;1) is the symbolic value of
- (1;0;1,0) for VDC Type ‘real’;
- (32767;32767) if VDC Type is ‘integer’.

**NOTE 8-8**
The default values of VDC EXTENT for VDC Type ‘real’ given in ISO 8632-1 and ISO 8632-3 are inconsistent. Due to these inconsistencies an arbitrary choice of‘(1,0;1,0)’ was made for the Second Corner.

### 6.1.2 Region of interest specification

This presentation attribute specifies the region of interest used when laying out and imaging the content of the basic object.

This presentation attribute consists of one of the following parameters:
- “rectangle”, consisting of two sub–parameters specifying the Virtual Device Coordinates for the first corner and the Virtual Device Coordinates for the second corner of the region of interest;
- “automatic”, not comprising any subparameters and its value is ‘null’.

The default value is the parameter “automatic”.

If the parameter “automatic” is specified the region of interest is the same as the VDC Extent.

If coordinate pairs for the first corner and second corner are specified using the parameter “rectangle” then the region of interest is specified by these values.

### 6.1.3 Picture orientation

This presentation attribute specifies with which corner of the basic layout object the first corner of the region of interest is to be made coincident.

This presentation attribute specifies one of the four corners of a basic layout object:
- 0° bottom left corner;
- 90° bottom right corner;
- 180° top right corner;
- 270° top left corner.

The default value is 0°, bottom left corner.

### 6.2 Layout presentation attributes

No layout presentation attributes are specified for this content architecture.

### 6.3 Logical presentation attributes

#### 6.3.1 Picture dimensions

This presentation attribute specifies the intended dimensions of the basic layout object that is to contain the image defined by the geometric graphics content portion.
The value of this attribute consists of one of four parameters:

a) “width controlled”;
b) “height controlled”;
c) “area controlled”;
d) “automatic”.

The parameter “width controlled” has two subparameters “minimum width” and “preferred width”.

The parameter “height controlled” has two subparameters “minimum height” and “preferred height”.

The parameter “area controlled” has five subparameters:
- “minimum width”;
- “preferred width”;
- “minimum height”;
- “preferred height”;
- “aspect ratio flag”.

The parameter “automatic” has no subparameters and its value is ‘null’.

The sub-parameter “aspect ratio flag” has the value ‘fixed’ or ‘variable’. All other sub-parameters have non-negative integer values in SMUs.

The default value of this attribute is the parameter “automatic”.

The values of “minimum width” and “preferred width” specify the lower limit and the upper limit of the allowed widths of the basic layout object. The value of the “minimum width” shall not be greater than the value of the “preferred width”.

The values of “minimum height” and “preferred height” specify the lower limit and the upper limit of the allowed heights of the basic layout object. The value of the “minimum height” shall not be greater than the value of the “preferred height”.

If either or both of the values for “preferred width” and “preferred height” are specified the dimensions of the basic layout object shall be as close to the corresponding specified values as possible.

“Aspect ratio flag” has one of the values ‘fixed’ or ‘variable’, specifying whether or not the aspect ratio of the basic layout object shall be equal to that of the region of interest.

If only the range of allowed widths for the basic layout object is specified (case a), this attribute specifies that the height of the basic layout object shall be such that the aspect ratio of the region of interest is maintained.

If only the range of allowed heights for the basic layout object is specified (case b), this attribute specifies that the width of the basic layout object shall be such that the aspect ratio of the region of interest is maintained.

If both the ranges of allowed width and heights are specified (case c) the value of “aspect ratio flag” determines whether or not the aspect ratio of the region of interest shall be maintained during the determination of the dimensions of the basic layout object.

If neither the range of allowed heights nor the range of allowed widths is specified (case d), this attribute specifies that the width of the basic layout object shall be equal to the dimension of the available area in that direction and that the height is constrained to maintain the aspect ratio of the region of interest.

### 6.4 Content architecture class attributes

#### 6.4.1 Content architecture class

The value of the attribute “content architecture class” of a basic component description that conforms to this part of this Standard is an ASN.1 object identifier with the value

\[
\{ 2 8 2 8 0 \}.
\]

#### 6.4.2 Content type

The attribute “content type” cannot be used to specify the content architecture defined in this part of this Standard.
6.5 Interaction with document architecture attributes
The value ‘concatenate’ of the layout directive attribute “concatenation” is ignored. This attribute is not taken into account during the layout of the geometric graphics content.

The layout directive attribute “indivisibility” may be ignored. It provides no additional constraint for the geometric graphics content layout process.

7. GEOMETRIC GRAPHICS CONTENT PORTIONS ATTRIBUTES

7.1 Common coding attributes
The value of the content portion attribute “type of coding” of a content portion description that conforms to this part of this Standard is an ASN.1 object identifier with the value
\{ 2 8 3 8 0 \}.

7.2 Content information
The value of the content portion attribute “content information” of a content portion description that conforms to this part of this Standard is an ASN.1 octet string representing a CGM conforming to the rules defined in ISO 8632–1 with the binary encoding defined in ISO 8632–3.

The relationship between part 8 of this Standard and ISO 8632 is such that
- the string specified by the attribute “content information” in a geometric graphics content portion is a complete CGM as defined in ISO 8632–1 and ISO 8632–3;
- any CGM as defined in ISO 8632–1 and ISO 8632–3 containing a single picture may be used as the value of a string specified by the attribute “content information” in a geometric graphics content portion.

NOTE 8-9
The presentation attributes specifying CGM defaults (see 6.1.1) are provided for applying the factorization mechanism of an ODA environment to data that may be shared among several geometric graphics content portions. If a geometric graphics content portion is provided by importing a CGM into the ODA environment, then extreme care should be used in any attempt to assign this CGM as a data value for the content portion attribute “content information” and using the presentation attributes to change the default values of the CGM. The effects of changing the default values of such an imported CGM could quite possibly make the interpretation of the CGM non-sensible or impossible. The presentation attributes that should especially be considered are those that would cause a misunderstanding of the CGM data (for example, the presentation attribute “geometric graphics encoding announce”).

7.3 Other coding attributes
No other coding attributes are defined in this part of this Standard.

8. FORMAL DEFINITIONS OF GEOMETRIC GRAPHICS CONTENT ARCHITECTURE DEPENDENT DATA TYPES

8.1 Introduction
This clause contains the formal definitions, in ASN.1 notation (defined in ISO 8824), of data types corresponding to presentation and coding attributes that are applicable to geometric graphics content architectures.

These data types are
- the data type to represent the geometric graphics content architecture specific presentation attributes in basic layout components, presentation styles and default value lists;
- the data type to represent the geometric graphics content architecture specific coding attributes in content portions;
- the data type to represent the non–basic values of the geometric graphics content architecture presentation attributes in the document profile;
- the data type to represent the non–basic values of the geometric graphics content architecture coding attributes in the document profile;
- the data type to represent the non–standard default values of geometric graphics content architecture presentation and coding attributes in the document profile.
8.2 Representation of geometric graphics presentation attributes

The data type "Geometric-Graphics-Attributes" contains a set of subordinate data types that specify the geometric graphics presentation attributes. Some of these subordinate data types are elementary but others are structured and themselves made up of subordinate data types. The format of these data types is given below.

The subset of subordinate data types that may occur within a particular instance of the data type "Geometric-Graphics-Attributes" depends upon the particular geometric graphics content architecture level that is specified.

```
Geo-Gr-Presentation-Attributes

9. CONTENT LAYOUT PROCESS

This clause describes a content layout process for basic logical objects associated with content architectures of type geometric graphics.

Its purpose is to aid understanding of the semantics of the presentation attributes by describing the required results of such a process. However, it is not intended to specify any process that might be carried out in a particular implementation to achieve these results.

9.1 Introduction

9.1.1 Purpose

The content layout process describes a process of laying out the geometric graphics content into an allocated area. This area is referred to as the available area and is determined by the document layout process described in part 2 of this Standard.

The purpose of the content layout process is to convert content associated with basic logical components into content associated with basic layout objects.

The content layout process results in the creation of a basic layout object into which the content shall be positioned. The dimensions of the basic layout object are returned to the document layout process which determines the precise position of that basic layout object within the available area.

9.1.2 Available area

The content layout process is constrained by the available area. The maximum dimensions that a basic layout object can take are constrained by the dimensions of the available area.

During the layout of content associated with a basic logical component into a basic layout object, the following cases can occur:
- the formatted processable content fits into the dimensions of the available area;
the formatted processable content does not fit into the dimensions of the available area; in this case, a new available area is required.

9.1.3 Presentation attributes
The content layout process takes into account the presentation attributes applying to the basic logical object with which the content is associated. The content layout process takes also into account the region of interest that may depend on CGM elements in the content portion.

The presentation attributes applying to the content layout process can be specified in the generic layout structure and presentation styles. The values of these presentation attributes are determined according to the defaulting rules specified in part 2 of this Standard.

9.1.4 Geometric graphics content architecture classes
The content layout process is specified for basic logical objects associated with the formatted processable form geometric graphics content architecture class. The content layout process does not modify the form of the content.

9.1.5 Layout of the content
For the geometric graphics content architecture class, one case of laying out the content of basic logical objects into layout objects is possible:

- single basic logical object to single basic layout object: the content associated with a single basic logical object can be laid out into a single basic layout object and is the only content associated with this basic layout object.

9.2 Content layout process for formatted processable content architecture class
Determination of the dimensions of the basic layout object depends on the value of the presentation attribute “picture dimensions” (the four possible cases are illustrated in figures 8-4 to 8-7):

a) The presentation attribute “picture dimensions” specifies a value for the parameter “width controlled”.

In this case the width of the picture will be within the range specified by the originator.

The determination of the basic layout object dimensions is constrained by the range of allowed widths given by the value of the parameter “width controlled”, the dimensions of the available area and the aspect ratio of the region of interest.

The dimensions of the basic layout object shall be determined such that: The basic layout object fits into the available area; the aspect ratio of the basic layout object is the same as that of the region of interest; and the width of the basic layout object has a value that is within the range of allowed widths. The width of the basic layout object shall in addition be determined such that the deviation from the value of “preferred width”, specified by the parameter “width controlled” is as small as possible.

b) The presentation attribute “picture dimensions” specifies a value for the parameter “height controlled”.

In this case the height of the picture will be within the range specified by the originator.

The determination of the basic layout object dimensions is constrained by the range of allowed heights given by the value of the parameter “height controlled”, the dimensions of the available area and the aspect ratio of the region of interest.

The dimensions of the basic layout object shall be determined such that: the basic layout object fits into the available area; the aspect ratio of the basic layout object is the same as that of the region of interest; and the height of the basic layout object has a value that is within the range of allowed heights. The height of the basic layout object shall in addition be determined such that the deviation from the value of “preferred height”, specified by the parameter “height controlled” is as small as possible.

c) The presentation attribute “picture dimensions” specifies a value for the parameter “area controlled”.

In this case the dimensions of the picture will be within the range specified by the originator. In particular, this can be used to ensure that a picture will have a fixed size.
The determination of the basic layout object dimensions is constrained by the range of allowed heights and widths given by the value of the parameter “area controlled”, the dimensions of the available area and, depending on the value of the sub-parameter “aspect ratio flag” of the parameter “area controlled”, by the aspect ratio of the region of interest.

The dimensions of the basic layout object shall be determined such that: The basic layout object fits into the available area; the width of the basic layout object has a value that is within the range of allowed widths; and the height of the basic layout object has a value that is within the range of allowed heights. If the value of the sub-parameter “aspect ratio flag” is ‘fixed’ there is the further constraint to the basic layout object dimensions, that the aspect ratio of the basic layout object shall be the same as that of the region of interest. Both the width and height of the basic layout object shall additionally be chosen such, that their deviations from their preferred values, specified by the parameter “area controlled” are both as small as possible.

d) The presentation attribute “picture dimensions” specifies a value for the parameter “automatic”.

In this case the picture dimensions are automatically adjusted to the page layout.

The determination of the basic layout object dimensions is constrained by the dimensions of the available area and the aspect ratio of the region of interest.

The dimensions of the basic layout object shall be determined such that: The basic layout object fits into the available area; the width of the basic layout object is given the same value as the dimension of the available area in that direction; and the height of the basic layout object is determined such, that the aspect ratio of the basic layout object dimensions is the same as that of the region of interest.

If the given constraints cannot be met, then no dimensions of the basic layout object are determined.

If the SCALING MODE is ‘metric’ it is required that the value of the parameter “area controlled” is the equivalent value in SMUs of the specified metric size, taking into account the document profile attribute “unit scaling”.

The dimensions of a basic layout object are restricted to integral multiples of 1 SMU.

The presentation attribute “picture orientation” may rotate the region of interest. The rotated region of interest is used for the calculation of the basic layout object dimensions.
The Geometric Graphics Content

Figure 8-4 – Diagrams used to illustrate the process of determining the basic layout object dimensions
Value of presentation attribute "picture dimensions" : automatic

- initial constraints

10. CONTENT IMAGING PROCESS

This clause describes a content imaging process for basic layout objects associated with content architectures of type geometric graphics.

Its purpose is to aid understanding of the semantics of the presentation attributes by describing the required results of such a process. However, it is not intended to specify any process that might be carried out in a particular implementation to achieve these results.

10.1 Introduction

The content imaging process is only concerned with the layout structures, the presentation styles and the content of basic layout components conforming to this part of this Standard.

The content imaging process is applicable to the formatted processable form geometric graphics content architecture class.

10.2 Content imaging process for formatted processable form content architecture class

This clause describes how the various shared presentation attributes and CGM elements determine the image of the content.

The imaging process is divided into two parts:

- initialisation;
- imaging.

10.2.1 Initialisation of the imaging process

At the start of the imaging of a geometric graphics content portion the imaging process is set to a default state. The default state of the imaging process is defined by the presentation attributes specifying CGM defaults (see 6.1.1) except those parameters overwritten by CGM elements explicitly specified in the geometric graphics content portion.

The imaging process uses bundle representations, pattern representations and colour representations specified by the bundle specification, pattern table specification and colour table specification parameter values, respectively, of the geometric graphics presentation attributes “line rendition”, “marker rendition”, “text rendition”, “filled area rendition”, “edge rendition” and “colour representations” in conjunction with the defaults for these representations defined in table 2, 3 and 4. After been set to its default state, the imaging process proceeds as if the CGM defaults have been explicitly specified in the content portion by CGM elements.

10.2.2 Imaging

Within geometric graphics content, geometric graphics elements are positioned in a Virtual Device Coordinate Space using a Virtual Device Coordinate system. For each basic layout object a part of the Virtual Device Coordinate Space specified by the region of interest is imaged according to the geometric graphics positioning principles (see clause 5). No part of the graphical image which extends beyond the boundaries of the basic layout object is imaged.

The imaging process ignores the element SCALING MODE as the required dimensions, and hence the aspect ratio, of the basic layout object have already been determined appropriately by the layout process.

In the case that the layout texture of the basic layout object specifies the combination “colourless, transparent” the picture descriptor element BACKGROUND COLOUR is ignored.

The support of external and escape elements is not required. A valid interpretation is to ignore them. The use of private unregistered escapes is not supported in open systems interchange.

Negative values of parameters of CGM elements are allowed. However, a valid interpretation is to ignore them; i.e. the use of private unregistered values is not supported in open systems interchange.

The image of the graphic elements is as specified by ISO 8632–1.
11. DEFINITION OF GEOMETRIC GRAPHICS CONTENT ARCHITECTURE CLASSES

There is only one geometric graphics content architecture class. This content architecture class provides for formatted processable form content. It is characterized as follows:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content architecture class :</td>
<td>Formatted processable form</td>
</tr>
<tr>
<td>CGM elements :</td>
<td>All defined in ISO 8632–1 and ISO 8632–3</td>
</tr>
<tr>
<td>Type of coding :</td>
<td>As defined in ISO 8632–3</td>
</tr>
<tr>
<td>Geometric graphics presentation attributes :</td>
<td>All listed in clause 6</td>
</tr>
<tr>
<td>CGM attributes :</td>
<td>All CGM attributes</td>
</tr>
</tbody>
</table>
Appendix A

Summary of ASN.1 object identifiers

(This Appendix is not part of the Standard)

Values of ASN.1 object identifiers are assigned in various clauses of this part of this Standard. These assignments are summarized in table A.1.

Appendix B

Recommendations for the development of geometric graphics content architecture levels in document application profiles

(This Appendix is not part of the Standard)

This appendix provides an example of the definition of a geometric graphics content architecture level. This content architecture level has been defined in accordance with the rules specified in part 1 of this Standard:

- GFP-0 is an example of a content architecture level belonging to the formatted processable form content architecture class. GFP-0 is mainly based on the minimum capabilities suggested in ISO 8632–1 and ISO 8632–3.

NOTE 8-B-1
The document application profile may have to specify additional rules for the use of these content architecture levels in particular applications. In particular, it may specify constraints to the values of parameters of CGM elements.

B.1 Geometric graphics content architecture level GFP-0

B.1.1 Content architecture class

GFP0 is a content architecture level derived from the formatted processable form content architecture class.

B.1.2 Presentation attributes

</table>
Tables 8–B.1 to 8–B.9 provide the BASIC values of the parameters of the presentation attributes specifying CGM defaults.

The third column of each table shows the relationship of the basic values to the complete set of permissible values as defined in the main body of part 8 of this Standard. In those cases where the basic values include all possible values allowed by part 8 of this Standard the entry in the third column is labelled ‘none’. For structured parameters the basic values and the relation to the complete set of permissible values of their components are given to indicate that all possible combinations of its components form the basic values and the complete set of permissible values of a parameter respectively.

B.1.3  **Content portion attributes**

No content portion attributes other than the document architecture attributes "type of coding" and "content information" are defined in this part of this Standard.
Appendix C

Basic differences between character primitives in the geometric graphics and the content of a basic component structured according to the character content architectures defined in part 6 of this Standard

(This Appendix is not part of the Standard)

This appendix identifies the basic differences between character strings regarded as graphical primitives and character content.

Within the geometric graphics content architecture (GGCA) the graphical primitive elements which may be used to describe a picture, include a text primitive. The text primitive permits the inclusion of textual information in geometric graphics pictures.

The most important basic differences between the text within the two different content architectures are as follows:

- Within GGCA each primitive is conceptually independent of any other within the same content portion. Within the character content architecture (CCA) all content is a single text string.
- Within GGCA a text primitive may be positioned anywhere in the VDC Space. Within CCA the positioning of characters is sequential in nature and, therefore, the position at which a character is imaged is derived from the position at which the predecessor was imaged.
- Within GGCA the size of the basic layout object is not affected by the text within the content portion. Within CCA the size of the basic layout object is totally dependent on the amount of text within the content portion.
- Within GGCA the orientation of a text primitive may be set to any angle relative to the Virtual Device Coordinate system first axis. Within CCA the character path must be at 0°, 90°, 180° or 270° relative to the horizontal axis of the layout object.
- Within GGCA the character size is specified by the CGM attribute elements CHARACTER HEIGHT and CHARACTER EXPANSION FACTOR and is conceptually independent of the font. This allows the aspect ratio of the character to be changed. Within CCA the character size is defined by the font.
- Within GGCA a text primitive is a geometric element and may undergo geometric transformation such as scaling and arbitrary rotation. Within CCA no such functionality exists.
- Within GGCA text primitives the effect of embedded control functions are not standardised (eg: \(<\text{CR}>\), \(<\text{LF}>\), \(<\text{HT}>\)). These control functions may occur but there is no definition of their semantics. Within CCA such control functions have a standardised effect.
- Within GGCA there is a character attribute which permits the inter-character space to be set or changed without constraint to a particular string of characters or a given line length. This permits the justification of either monospaced or proportionally spaced fonts. Within CCA, such justification can be specified as a requirement in the logical text, but resolves to embedded control functions working in unit of SMU in the laid out (formatted) text.
