    9.2.15 GetNumberOption (options, property, minimum, maximum, fallback)
9.2.16 PartitionPattern (pattern)

10 Collator Objects

10.1 The Intl.Collator Constructor
10.1.1 InitializeCollator (collator, locales, options)
10.1.2 Intl.Collator ([locales[,options]])

10.2 Properties of the Intl.Collator Constructor
10.2.1 Intl.Collator.prototype
10.2.2 Intl.Collator.supportedLocalesOf (locales[,options])
10.2.3 Internal Slots

10.3 Properties of the Intl.Collator Prototype Object
10.3.1 Intl.Collator.prototype.constructor
10.3.2 Intl.Collator.prototype[@@toStringTag]
10.3.3 Collator Compare Functions
10.3.3.1 CompareStrings (collator, x, y)
10.3.4 Intl.Collator.prototype.resolvedOptions()

10.4 Properties of Intl.Collator Instances

11 DateTimeFormat Objects

11.1 Abstract Operations for DateTimeFormat Objects
11.1.1 InitializeDateTimeFormat (dateTimeFormat, locales, options)
11.1.2 ToDateTimeOptions (options, required, defaults)
11.1.3 DateTimeStyleFormat (dateStyle, timeStyle, styles)
11.1.4 BasicFormatMatcher (options, formats)
11.1.5 BestFitFormatMatcher (options, formats)
11.1.6 DateTime Format Functions
11.1.7 FormatDateTimePattern (dateTimeFormat, patternParts, x, rangeFormatOptions)
11.1.8 PartitionDateTimePattern (dateTimeFormat, x)
11.1.9 FormatDateTime (dateTimeFormat, x)
11.1.10 FormatDateTimeToParts (dateTimeFormat, x)
11.1.11 PartitionDateTimeRangePattern (dateTimeFormat, x, y)
11.1.12 FormatDateTimeRange (dateTimeFormat, x, y)
11.1.13 FormatDateTimeRangeToParts (dateTimeFormat, x, y)
11.1.14 ToLocalTime (t, calendar, timeZone)
11.1.15 UnwrapDateTimeFormat (df)
11.2 The Intl.DateTimeFormat Constructor
11.2.1 Intl.DateTimeFormat ([locales[,options]])
11.3 Properties of the Intl.DateTimeFormat Constructor
11.3.1 Intl.DateTimeFormat.prototype
11.3.2 Intl.DateTimeFormat.prototype.supportedLocalesOf (locales[,options])
11.3.3 Internal slots

11.4 Properties of the Intl.DateTimeFormat Prototype Object
11.4.1 Intl.DateTimeFormat.prototype.constructor
11.4.2 Intl.DateTimeFormat.prototype[@@toStringTag]
11.4.3 get Intl.DateTimeFormat.prototype.format
11.4.4 Intl.DateTimeFormat.prototype.formatToParts (date)
11.4.5 Intl.DateTimeFormat.prototype.formatRange (startDate, endDate)
11.4.6 Intl.DateTimeFormat.prototype.formatRangeToParts (startDate, endDate)
11.4.7 Intl.DateTimeFormat.prototype.resolvedOptions()

11.5 Properties of Intl.DateTimeFormat Instances

12 DisplayNames Objects

12.1 Abstract Operations for DisplayNames Objects
12.1.1 CanonicalCodeForDisplayNames (type, code)
12.2 The Intl.DisplayNames Constructor
12.2.1 Intl.DisplayNames (locales, options)
12.3 Properties of the Intl.DisplayNames Constructor
12.3.1 Intl.DisplayNames.prototype
12.3.2 Intl.DisplayNames.supportedLocalesOf (locales, options)
12.3.3 Internal slots

12.4 Properties of the Intl.DisplayNames Prototype Object
12.4.1 Intl.DisplayNames.prototype.constructor
12.4.2 Intl.DisplayNames.prototype[@@toStringTag]
12.4.3 Intl.DisplayNames.prototype.of (code)
12.4.4 Intl.DisplayNames.prototype.resolvedOptions()

12.5 Properties of Intl.DisplayNames Instances

13 ListFormat Objects
13.1 Abstract Operations for ListFormat Objects
13.1.1 DeconstructPattern (pattern, placeables)
13.1.2 CreatePartsFromList (listFormat, list)
13.1.3 FormatList (listFormat, list)
13.1.4 FormatListToParts (listFormat, list)
13.1.5 StringListFromIterable (iterable)

13.2 The Intl.ListFormat Constructor
13.2.1 Intl.ListFormat ([locales, options])

13.3 Properties of the Intl.ListFormat Constructor
13.3.1 Intl.ListFormat.prototype
13.3.2 Intl.ListFormat.supportedLocalesOf (locales, options)
13.3.3 Internal slots

13.4 Properties of the Intl.ListFormat Prototype Object
13.4.1 Intl.ListFormat.prototype.constructor
13.4.2 Intl.ListFormat.prototype[@@toStringTag]
13.4.3 Intl.ListFormat.prototype.format (list)
13.4.4 Intl.ListFormat.prototype.formatToParts (list)
13.4.5 Intl.ListFormat.prototype.resolvedOptions()

13.5 Properties of Intl.ListFormat Instances

14 Locale Objects
14.1 The Intl.Locale Constructor
14.1.1 ApplyOptionsToTag (tag, options)
14.1.2 ApplyUnicodeExtensionToTag (tag, options, relevantExtensionKeys)
14.1.3 Intl.Locale (tag [, options])

14.2 Properties of the Intl.Locale Constructor
14.2.1 Intl.Locale.prototype
14.2.2 Internal slots

14.3 Properties of the Intl.Locale Prototype Object
14.3.1 Intl.Locale.prototype.constructor
14.3.2 Intl.Locale.prototype[@@toStringTag]
14.3.3 Intl.Locale.prototype.maximize()
14.3.4 Intl.Locale.prototype.minimize()
14.3.5 Intl.Locale.prototype.toString()
14.3.6 get Intl.Locale.prototype.baseName
14.3.7 get Intl.Locale.prototype.calendar
14.3.8 get Intl.Locale.prototype.caseFirst
14.3.9 get Intl.Locale.prototype.collation
14.3.10 get Intl.Locale.prototype.hourCycle
14.3.11 get Intl.Locale.prototype.numeric
14.3.12 get Intl.Locale.prototype.numberingSystem
14.3.13 get Intl.Locale.prototype.language
14.3.14 get Intl.Locale.prototype.script
14.3.15 get Intl.Locale.prototype.region

15 NumberFormat Objects
15.1 Abstract Operations for NumberFormat Objects
15.1.1 SetNumberFormatDigitOptions ( intlObj, options, mnfdDefault, mxfdDefault, notation )
15.1.2 InitializeNumberFormat ( numberFormat, locales, options )
15.1.3 CurrencyDigits ( currency )
15.1.4 Number Format Functions
15.1.5 FormatNumericToString ( intlObject, x )
15.1.6 PartitionNumberPattern ( numberFormat, x )
15.1.7 PartitionNotationSubPattern ( numberFormat, x, n, exponent )
15.1.8 FormatNumeric ( numberFormat, x )
15.1.9 FormatNumericToParts ( numberFormat, x )
15.1.10 ToRawPrecision ( x, minPrecision, maxPrecision )
15.1.11 ToRawFixed ( x, minInteger, minFraction, maxFraction )
15.1.12 UnwrapNumberFormat ( nf )
15.1.13 SetNumberFormatUnitOptions ( intlObj, options )
15.1.14 GetNumberFormatPattern ( numberFormat, x )
15.1.15 GetNotationSubPattern ( numberFormat, exponent )
15.1.16 ComputeExponent ( numberFormat, x )
15.1.17 ComputeExponentForMagnitude ( numberFormat, magnitude )
15.2 The Intl.NumberFormat Constructor
15.2.1 Intl.NumberFormat ( [ locales [, options ] ] )
15.3 Properties of the Intl.NumberFormat Constructor
15.3.1 Intl.NumberFormat.prototype
15.3.2 Intl.NumberFormat.supportedLocalesOf ( locales [, options ] )
15.3.3 Internal slots
15.4 Properties of the Intl.NumberFormat Prototype Object
15.4.1 Intl.NumberFormat.prototype.constructor
15.4.2 Intl.NumberFormat.prototype [ @@toStringTag ]
15.4.3 get Intl.NumberFormat.prototype.format
15.4.4 Intl.NumberFormat.prototype.formatToParts ( value )
15.4.5 Intl.NumberFormat.prototype.resolvedOptions ( )
15.5 Properties of Intl.NumberFormat Instances
16 PluralRules Objects
16.1 Abstract Operations for PluralRules Objects
16.1.1 InitializePluralRules ( pluralRules, locales, options )
16.1.2 GetOperands ( s )
16.1.3 PluralRuleSelect ( locale, type, n, operands )
16.1.4 ResolvePlural ( pluralRules, n )
16.2 The Intl.PluralRules Constructor
16.3 Properties of the Intl.PluralRules Constructor
16.3.1 Intl.PluralRules.prototype
16.3.2 Intl.PluralRules.supportedLocalesOf ( locales [, options ] )
16.3.3 Internal slots
16.4.1 Intl.PluralRules.prototype.constructor
16.4.2 Intl.PluralRules.prototype [ @@toStringTag ]
16.4.3 Intl.PluralRules.prototype.select ( value )
16.4.4 Intl.PluralRules.prototype.resolvedOptions ( )
16.5 Properties of Intl.PluralRules Instances
17 RelativeTimeFormat Objects
17.1 Abstract Operations for RelativeTimeFormat Objects
17.1.1 InitializeRelativeTimeFormat ( relativeTimeFormat, locales, options )
17.1.2 SingularRelativeTimeUnit ( unit )
17.1.3 PartitionRelativeTimePattern ( relativeTimeFormat, value, unit )
17.1.4 MakePartsList ( pattern, unit, parts )
17.1.5 FormatRelativeTime ( relativeTimeFormat, value, unit )
17.1.6 FormatRelativeTimeToParts (relativeTimeFormat, value, unit)

17.2 The Intl.RelativeTimeFormat Constructor
17.2.1 Intl.RelativeTimeFormat ([locales, options])

17.3 Properties of the Intl.RelativeTimeFormat Constructor
17.3.1 Intl.RelativeTimeFormat.prototype
17.3.2 Intl.RelativeTimeFormat.supportedLocalesOf (locales, options)
17.3.3 Internal slots

17.4 Properties of the Intl.RelativeTimeFormat Prototype Object
17.4.1 Intl.RelativeTimeFormat.prototype.constructor
17.4.2 Intl.RelativeTimeFormat.prototype[@@toStringTag]
17.4.3 Intl.RelativeTimeFormat.prototype.format (value, unit)
17.4.4 Intl.RelativeTimeFormat.prototype.formatToParts (value, unit)
17.4.5 Intl.RelativeTimeFormat.prototype.resolvedOptions()

17.5 Properties of Intl.RelativeTimeFormat Instances

18 Locale Sensitive Functions of the ECMAScript Language Specification

18.1 Properties of the String Prototype Object
18.1.1 String.prototype.localeCompare (that, locales, options)
18.1.2 String.prototype.toLocaleLowerCase (locales)
18.1.3 String.prototype.toLocaleUpperCase (locales)

18.2 Properties of the Number Prototype Object
18.2.1 Number.prototype.toLocaleString (locales, options)

18.3 Properties of the BigInt Prototype Object
18.3.1 BigInt.prototype.toLocaleString (locales, options)

18.4 Properties of the Date Prototype Object
18.4.1 Date.prototype.toLocaleString (locales, options)
18.4.2 Date.prototype.toLocaleDateString (locales, options)
18.4.3 Date.prototype.toLocaleTimeString (locales, options)

18.5 Properties of the Array Prototype Object
18.5.1 Array.prototype.toLocaleString (locales, options)

Introduction

This specification’s source can be found at https://github.com/tc39/ecma402.

The ECMAScript 2021 Internationalization API Specification (ECMA-402 8th Edition), provides key language sensitive functionality as a complement to the ECMAScript 2021 Language Specification (ECMA-262 12th Edition or successor). Its functionality has been selected from that of well-established internationalization APIs such as those of the Internationalization Components for Unicode (ICU) library, of the .NET framework, or of the Java platform.

The 1st Edition API was developed by an ad-hoc group established by Ecma TC39 in September 2010 based on a proposal by Nebojša Ćirić and Jungshik Shin.

The 2nd Edition API was adopted by the General Assembly of June 2015, as a complement to the ECMAScript 6th Edition.

The 3rd Edition API was the first edition released under Ecma TC39’s new yearly release cadence and open development process. A plain-text source document was built from the ECMA-402 source document to serve as the base for further development entirely on GitHub. Over the year of this standard’s development, dozens of pull requests and issues were filed representing several of bug
This Standard defines the application programming interface for ECMAScript objects that support programs that need to adapt to the linguistic and cultural conventions used by different human languages and countries.

2 Conformance

A conforming implementation of the ECMAScript 2021 Internationalization API Specification must conform to the ECMAScript 2021 Language Specification (ECMA-262 12th Edition, or successor), and must provide and support all the objects, properties, functions, and program semantics described in this specification.

A conforming implementation of the ECMAScript 2021 Internationalization API Specification is permitted to provide additional objects, properties, and functions beyond those described in this specification. In particular, a conforming implementation of the ECMAScript 2021 Internationalization API Specification is permitted to provide properties not described in this specification, and values for those properties, for objects that are described in this specification. A conforming implementation is not permitted to add optional arguments to the functions defined in this specification.

A conforming implementation is permitted to accept additional values, and then have implementation-defined behaviour instead of throwing a `RangeError`, for the following properties of `options` arguments:

- The `options` property "localeMatcher" in all constructors and `supportedLocalesOf` methods.
The `options` properties "usage" and "sensitivity" in the Collator constructor.

The `options` properties "style", "currencyDisplay", "notation", "compactDisplay", "signDisplay", "currencySign", and "unitDisplay" in the NumberFormat constructor.

The `options` properties "minimumIntegerDigits", "minimumFractionDigits", "maximumFractionDigits", "minimumSignificantDigits", and "maximumSignificantDigits" in the NumberFormat constructor, provided that the additional values are interpreted as integer values higher than the specified limits.

The `options` properties listed in Table 4 in the DateTimeFormat constructor.

The `options` property "formatMatcher" in the DateTimeFormat constructor.

The `options` properties "minimumIntegerDigits", "minimumFractionDigits", "maximumFractionDigits", and "minimumSignificantDigits" in the PluralRules constructor, provided that the additional values are interpreted as integer values higher than the specified limits.

The `options` property "type" in the PluralRules constructor.

The `options` property "style" and "numeric" in the RelativeTimeFormat constructor.

The `options` property "style" and "type" in the DisplayNames constructor.

3 Normative References

The following referenced documents are required for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

4 Overview

This section contains a non-normative overview of the ECMAScript 2021 Internationalization API Specification.

4.1 Internationalization, Localization, and Globalization
Internationalization of software means designing it such that it supports or can be easily adapted to support the needs of users speaking different languages and having different cultural expectations, and enables worldwide communication between them. Localization then is the actual adaptation to a specific language and culture. Globalization of software is commonly understood to be the combination of internationalization and localization. Globalization starts at the lowest level by using a text representation that supports all languages in the world, and using standard identifiers to identify languages, countries, time zones, and other relevant parameters. It continues with using a user interface language and data presentation that the user understands, and finally often requires product-specific adaptations to the user’s language, culture, and environment.

The ECMAScript 2021 Language Specification lays the foundation by using Unicode for text representation and by providing a few language-sensitive functions, but gives applications little control over the behaviour of these functions. The ECMAScript 2021 Internationalization API Specification builds on this by providing a set of customizable language-sensitive functionality. The API is useful even for applications that themselves are not internationalized, as even applications targeting only one language and one region need to properly support that one language and region. However, the API also enables applications that support multiple languages and regions, even concurrently, as may be needed in server environments.

4.2 API Overview

The ECMAScript 2021 Internationalization API Specification is designed to complement the ECMAScript 2021 Language Specification by providing key language-sensitive functionality. The API can be added to an implementation of the ECMAScript 2021 Language Specification (ECMA-262 12th Edition, or successor).

The ECMAScript 2021 Internationalization API Specification provides several key pieces of language-sensitive functionality that are required in most applications: String comparison (collation), number formatting, date and time formatting, display names, list formatting, pluralization rules, and case conversion. While the ECMAScript 2021 Language Specification provides functions for this basic functionality (on Array.prototype: toLocaleString; on String.prototype: localeCompare, toLocaleLowerCase, toLocaleUpperCase; on Number.prototype: toLocaleString; on Date.prototype: toLocaleString, toLocaleDateString, and toLocaleTimeString), it leaves the actual behaviour of these functions largely up to implementations to define. The ECMAScript 2021 Internationalization API Specification provides additional functionality, control over the language and over details of the behaviour to be used, and a more complete specification of required functionality.

Applications can use the API in two ways:

1. Directly, by using the constructors Intl.Collator, Intl.DateTimeFormat, Intl.DisplayNames, Intl.ListFormat, Intl.NumberFormat, Intl.PluralRules, or Intl.RelativeTimeFormat to construct an object, specifying a list of preferred languages and options to configure the behaviour of the resulting object. The object then provides a main function (compare, select, or format), which can be called repeatedly. It also provides a resolvedOptions function, which the application can use to find out the exact configuration of the object.
2. Indirectly, by using the functions of the ECMAScript 2021 Language Specification mentioned above. The collation and formatting functions are respecified in this specification to accept the same arguments as the Collator, NumberFormat, and DateTimeFormat constructors and produce the same results as their compare or format methods. The case conversion functions are respecified to accept a list of preferred languages.

The Intl object is used to package all functionality defined in the ECMAScript 2021 Internationalization API Specification to avoid name collisions.

NOTE While the API includes a variety of formatters, it does not provide any parsing facilities. This is intentional, has been discussed extensively, and concluded after
weighting in all the benefits and drawbacks of including said functionality. See the discussion on the issue tracker.

4.3 API Conventions

Every built-in constructor should behave as if defined inside a class, throwing a TypeError exception when called as a function (without NewTarget). For backwards compatibility with past editions, this does not apply to %Collator%, %NumberFormat%, or %DateTimeFormat%, each of which construct and return a new object when called as a function.

4.4 Implementation Dependencies

Due to the nature of internationalization, the API specification has to leave several details implementation dependent:

- The set of locales that an implementation supports with adequate localizations: Linguists estimate the number of human languages to around 6000, and the more widely spoken ones have variations based on regions or other parameters. Even large locale data collections, such as the Common Locale Data Repository, cover only a subset of this large set. Implementations targeting resource-constrained devices may have to further reduce the subset.

- The exact form of localizations such as format patterns: In many cases locale-dependent conventions are not standardized, so different forms may exist side by side, or they vary over time. Different internationalization libraries may have implemented different forms, without any of them being actually wrong. In order to allow this API to be implemented on top of existing libraries, such variations have to be permitted.

- Subsets of Unicode: Some operations, such as collation, operate on strings that can include characters from the entire Unicode character set. However, both the Unicode standard and the ECMAScript standard allow implementations to limit their functionality to subsets of the Unicode character set. In addition, locale conventions typically don’t specify the desired behaviour for the entire Unicode character set, but only for those characters that are relevant for the locale. While the Unicode Collation Algorithm combines a default collation order for the entire Unicode character set with the ability to tailor for local conventions, subsets and tailoring will still result in differences in behaviour.

4.4.1 Compatibility across implementations

ECMA 402 describes the schema of the data used by its functions. The data contained inside is implementation-dependent, and expected to change over time and vary between implementations. The variation is visible by programmers, and it is possible to construct programs which will depend on a particular output. However, this specification attempts to describe reasonable constraints which will allow well-written programs to function across implementations. Implementations are encouraged to continue their efforts to harmonize linguistic data.

5 Notational Conventions

This standard uses a subset of the notational conventions of the ECMAscript 2021 Language Specification (ECMA-262 12th Edition), as ES2021:

- Object Internal Methods and Internal Slots, as described in ES2021, 6.1.7.2.
- Algorithm conventions, as described in ES2021, 5.2, and the use of abstract operations, as described in ES2021, 7.1, 7.2, 7.3, 7.4.
- Internal Slots, as described in ES2021, 9.1.
- The List and Record Specification Type, as described in ES2021, 6.2.1.

**NOTE**

As described in the ECMAScript Language Specification, algorithms are used to precisely specify the required semantics of ECMAScript constructs, but are not intended to imply the use of any specific implementation technique. Internal slots are used to define the semantics of object values, but are not part of the API. They are defined purely for expository purposes. An implementation of the API must behave as if it produced and operated upon internal slots in the manner described here.

As an extension to the Record Specification Type, the notation "[[<name>]]" denotes a field whose name is given by the variable `name`, which must have a String value. For example, if a variable `s` has the value "a", then `[[<s>]]` denotes the field `[[a]]`.

This specification uses blocks demarcated as Normative Optional to denote the sense of Annex B in ECMA 262. That is, normative optional sections are required when the ECMAScript host is a web browser. The content of the section is normative but optional if the ECMAScript host is not a web browser.

### 5.1 Well-Known Intrinsic Objects

The following table extends the Well-Known Intrinsic Objects table defined in ES2021, 6.1.7.4.

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Global Name</th>
<th>ECMAScript Language Association</th>
</tr>
</thead>
<tbody>
<tr>
<td>%Collator%</td>
<td>Intl.Collator</td>

### 6 Identification of Locales, Currencies, Time Zones, and Measurement Units
This clause describes the String values used in the ECMAScript 2021 Internationalization API Specification to identify locales, currencies, time zones, and measurement units.

### 6.1 Case Sensitivity and Case Mapping

The String values used to identify locales, currencies, and time zones are interpreted in a case-insensitive manner, treating the Unicode Basic Latin characters "A" to "Z" (U+0041 to U+005A) as equivalent to the corresponding Basic Latin characters "a" to "z" (U+0061 to U+007A). No other case folding equivalences are applied. When mapping to upper case, a mapping shall be used that maps characters in the range "a" to "z" (U+0061 to U+007A) to the corresponding characters in the range "A" to "Z" (U+0041 to U+005A) and maps no other characters to the latter range.

**NOTE** For example, "ß" (U+00DF) must not match or be mapped to "SS" (U+0053, U+0053). "ı" (U+0131) must not match or be mapped to "I" (U+0049).

### 6.2 Language Tags

The ECMAScript 2021 Internationalization API Specification identifies locales using Unicode BCP 47 locale identifiers as defined by Unicode Technical Standard #35 LDML § 3 Unicode Language and Locale Identifiers, which may include extensions such as the Unicode BCP 47 U Extension. Their canonical form is specified in Unicode Technical Standard #35 LDML § 3.2.1 Canonical Unicode Locale Identifiers.

Unicode BCP 47 locale identifiers are structurally valid when they match those syntactical formatting criteria of Unicode Technical Standard 35, section 3.2, but it is not required to validate them according to the Unicode validation data. All structurally valid language tags are valid for use with the APIs defined by this standard. However, the set of locales and thus language tags that an implementation supports with adequate localizations is implementation dependent. The constructors Collator, NumberFormat, DateTimeFormat, PluralRules, ListFormat, and DisplayNames map the language tags used in requests to locales supported by their respective implementations.

#### 6.2.1 Unicode Locale Extension Sequences

This standard uses the term "Unicode locale extension sequence" - as described in `unicode_locale_extensions` in UTS 35 Unicode Locale Identifier, section 3.2 - for any substring of a language tag that is not part of a private use subtag sequence, starts with a separator "," and the singleton "u", and includes the maximum sequence of following non-singleton subtags and their preceding "," separators.

#### 6.2.2 IsStructurallyValidLanguageTag (locale)

The IsStructurallyValidLanguageTag abstract operation determines whether the locale argument (which must be a String value) is a language tag recognized by this specification. (It does not consider whether the language tag conveys any meaningful semantics, differentiate between aliased subtags and their preferred replacement subtags, or require canonical casing or subtag ordering.)

IsStructurallyValidLanguageTag returns true if all of the following conditions hold, false otherwise:

- locale can be generated from the EBNF grammar for `unicode_locale_id` in Unicode Technical Standard #35 LDML § 3.2 Unicode Locale Identifier;
- locale does not use any of the backwards compatibility syntax described in Unicode Technical Standard #35 LDML § 3.3 BCP 47 Conformance;
the `unicode_language_id` within `locale` contains no duplicate `unicode_variant_subtag` subtags; and

if `locale` contains an `extensions*` component, that component
  - does not contain any `other_extensions` components with duplicate `[alphanum-[-tTuUxX]]` subtags,
  - contains at most one `unicode_locale_extensions` component,
  - contains at most one `transformed_extensions` component, and
  - if a `transformed_extensions` component that contains a `tlang` component is present, then
    * the `tlang` component contains no duplicate `unicode_variant_subtag` subtags.

When evaluating each condition, terminal value characters in the grammar are interpreted as the corresponding ASCII code points. Subtags are duplicates if they are ASCII case-insensitively equivalent.

---

**NOTE** Every string for which this function returns `true` is both a "Unicode BCP 47 locale identifier", consistent with Unicode Technical Standard #35 LDML § 3.2 Unicode Locale Identifier and Unicode Technical Standard #35 LDML § 3.3 BCP 47 Conformance, and a valid BCP 47 language tag.

---

### 6.2.3 CanonicalizeUnicodeLocaleId ( `locale` )

The CanonicalizeUnicodeLocaleId abstract operation returns the canonical and case-regularized form of the `locale` argument (which must be a String value for which `IsStructurallyValidLanguageTag(locale)` equals `true`). The following steps are taken:

1. Let `localeId` be the string `locale` after performing the algorithm to transform it to canonical syntax per Unicode Technical Standard #35 LDML § 3.2.1 Canonical Unicode Locale Identifiers. (The result is a Unicode BCP 47 locale identifier, in canonical syntax but not necessarily in canonical form.)
2. Let `localeId` be the string `localeId` after performing the algorithm to transform it to canonical form. (The result is a Unicode BCP 47 locale identifier, in both canonical syntax and canonical form.)
3. If `localeId` contains a substring `extension` that is a Unicode locale extension sequence, then
   a. Let `components` be `! UnicodeExtensionComponents(extension)`.
   b. Let `attributes` be `components`.[[Attributes]].
   c. Let `keywords` be `components`.[[Keywords]].
   d. Let `newExtension` be "u".
   e. For each element `attr` of `attributes`, do
      i. Append ":" to `newExtension`.
      ii. Append `attr` to `newExtension`.
   f. For each `Record` `[[Key],[[Value]]] keyword` in `keywords`, do
      i. Append ":" to `newExtension`.
      ii. Append `keyword`[[Key]] to `newExtension`.
      iii. If `keyword`[[Value]] is not the empty String, then
          1. Append ":" to `newExtension`.
          2. Append `keyword`[[Value]] to `newExtension`.
   g. Assert: `newExtension` is not equal to "u".
   h. Let `localeId` be `localeId` with the substring corresponding to `extension` replaced by the string `newExtension`.
4. Return `localeId`.

---

**NOTE** The third step of this algorithm ensures that a Unicode locale extension sequence...
6.2.4 DefaultLocale ()

The DefaultLocale abstract operation returns a String value representing the structurally valid (6.2.2) and canonicalized (6.2.3) Unicode BCP 47 locale identifier for the host environment's current locale.

6.3 Currency Codes

The ECMAScript 2021 Internationalization API Specification identifies currencies using 3-letter currency codes as defined by ISO 4217. Their canonical form is upper case.

All well-formed 3-letter ISO 4217 currency codes are allowed. However, the set of combinations of currency code and language tag for which localized currency symbols are available is implementation dependent. Where a localized currency symbol is not available, the ISO 4217 currency code is used for formatting.

6.3.1 IsWellFormedCurrencyCode (currency)

The IsWellFormedCurrencyCode abstract operation verifies that the currency argument (which must be a String value) represents a well-formed 3-letter ISO currency code. The following steps are taken:

1. Let normalized be the result of mapping currency to upper case as described in 6.1.
2. If the number of elements in normalized is not 3, return false.
3. If normalized contains any character that is not in the range "A" to "Z" (U+0041 to U+005A), return false.
4. Return true.

6.4 Time Zone Names

The ECMAScript 2021 Internationalization API Specification identifies time zones using the Zone and Link names of the IANA Time Zone Database. Their canonical form is the corresponding Zone name in the casing used in the IANA Time Zone Database.

All registered Zone and Link names are allowed. Implementations must recognize all such names, and use best available current and historical information about their offsets from UTC and their daylight saving time rules in calculations. However, the set of combinations of time zone name and language tag for which localized time zone names are available is implementation dependent.

6.4.1 IsValidTimeZoneName (timeZone)

The IsValidTimeZoneName abstract operation verifies that the timeZone argument (which must be a String value) represents a valid Zone or Link name of the IANA Time Zone Database.

The abstract operation returns true if timeZone, converted to upper case as described in 6.1, is equal to one of the Zone or Link names of the IANA Time Zone Database, converted to upper case as described in 6.1. It returns false otherwise.

6.4.2 CanonicalizeTimeZoneName
The CanonicalizeTimeZoneName abstract operation returns the canonical and case-regularized form of the `timeZone` argument (which must be a String value that is a valid time zone name as verified by the `IsValidTimeZoneName` abstract operation). The following steps are taken:

1. Let `ianaTimeZone` be the Zone or Link name of the IANA Time Zone Database such that `timeZone`, converted to upper case as described in 6.1, is equal to `ianaTimeZone`, converted to upper case as described in 6.1.
2. If `ianaTimeZone` is a Link name, let `ianaTimeZone` be the corresponding Zone name as specified in the "backward" file of the IANA Time Zone Database.
3. If `ianaTimeZone` is "Etc/UTC" or "Etc/GMT", return "UTC".
4. Return `ianaTimeZone`.

The Intl.DateTimeFormat constructor allows this time zone name; if the time zone is not specified, the host environment's current time zone is used. Implementations shall support UTC and the host environment's current time zone (if different from UTC) in formatting.

6.4.3 DefaultTimeZone(

The DefaultTimeZone abstract operation returns a String value representing the valid (6.4.1) and canonicalized (6.4.2) time zone name for the host environment's current time zone.

6.5 Measurement Unit Identifiers

The ECMAScript 2021 Internationalization API Specification identifies measurement units using a core unit identifier as defined by Unicode Technical Standard #35, Part 2, Section 6. Their canonical form is a string containing all lowercase letters with zero or more hyphens.

Only a limited set of core unit identifiers are allowed. An illegal core unit identifier results in a RangeError.

6.5.1 IsWellFormedUnitIdentifier (unitIdentifier)

The IsWellFormedUnitIdentifier abstract operation verifies that the `unitIdentifier` argument (which must be a String value) represents a well-formed core unit identifier as defined in UTS #35, Part 2, Section 6. In addition to obeying the UTS #35 core unit identifier syntax, `unitIdentifier` must be one of the identifiers sanctioned by UTS #35 or be a compound unit composed of two sanctioned simple units. The following steps are taken:

1. If the result of `IsSanctionedSimpleUnitIdentifier(unitIdentifier)` is `true`, then
   a. Return `true`.
2. If the substring "-per-" does not occur exactly once in `unitIdentifier`, then
   a. Return `false`.
3. Let `numerator` be the substring of `unitIdentifier` from the beginning to just before "-per-".
4. If the result of `IsSanctionedSimpleUnitIdentifier(numerator)` is `false`, then
   a. Return `false`.
5. Let `denominator` be the substring of `unitIdentifier` from just after "-per-" to the end.
6. If the result of `IsSanctionedSimpleUnitIdentifier(denominator)` is `false`, then
   a. Return `false`.
7. Return `true`.

6.5.2 IsSanctionedSimpleUnitIdentifier (unitIdentifier)

The IsSanctionedSimpleUnitIdentifier abstract operation verifies that the given core unit identifier is among the simple units sanctioned in the current version of the ECMAScript Internationalization API Specification, a subset of the Validity Data as described in UTS #35, Part 1, Section 3.11; the list may
grow over time. As discussed in UTS #35, a simple unit is one that does not have a numerator and denominator. The following steps are taken:

1. If `unitIdentifier` is listed in Table 2 below, return `true`.
2. Else, return `false`.

7 Requirements for Standard Built-in ECMAScript Objects

Unless specified otherwise in this document, the objects, functions, and constructors described in this standard are subject to the generic requirements and restrictions specified for standard built-in ECMAScript objects in the ECMAScript 2021 Language Specification, 12th edition, clause 17, or successor.

8 The Intl Object

The Intl object is the %Intl% intrinsic object and the initial value of the "Intl" property of the global object. The Intl object is a single ordinary object.

The value of the [[Prototype]] internal slot of the Intl object is the intrinsic object %Object.prototype%.

The Intl object is not a function object. It does not have a [[Construct]] internal method; it is not possible to use the Intl object as a constructor with the new operator. The Intl object does not have a [[Call]] internal method; it is not possible to invoke the Intl object as a function.

The Intl object has an internal slot, [[FallbackSymbol]], which is a new %Symbol% in the current realm with the [[Description]] "IntlLegacyConstructedSymbol".

8.1 Value Properties of the Intl Object

8.1.1 Intl[@@toStringTag]
The initial value of the @@toStringTag property is the String value "Intl".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

### 8.2 Constructor Properties of the Intl Object

#### 8.2.1 Intl.Collator ( . . . )

See 10.

#### 8.2.2 Intl.DateTimeFormat ( . . . )

See 11.

#### 8.2.3 Intl.DisplayNames ( . . . )

See 12.

#### 8.2.4 Intl.ListFormat ( . . . )

See 13.

#### 8.2.5 Intl.Locale ( . . . )

See 14.

#### 8.2.6 Intl.NumberFormat ( . . . )

See 15.

#### 8.2.7 Intl.PluralRules ( . . . )

See 16.

#### 8.2.8 Intl.RelativeTimeFormat ( . . . )

See 17.

**NOTE** In ECMA 402 v1, Intl constructors supported a mode of operation where calling them with an existing object as a receiver would transform the receiver into the relevant Intl instance with all internal slots. In ECMA 402 v2, this capability was removed, to avoid adding internal slots on existing objects. In ECMA 402 v3, the capability was re-added as "normative optional" in a mode which chains the underlying Intl instance on any object, when the constructor is called. See Issue 57 for details.

### 8.3 Function Properties of the Intl Object

#### 8.3.1 Intl.getCanonicalLocales ( locales )
When the `getCanonicalLocales` method is called with argument `locales`, the following steps are taken:

1. Let `ll` be ? `CanonicalizeLocaleList(locales)`.  
2. Return `CreateArrayFromList(ll)`.

### 9 Locale and Parameter Negotiation

The constructors for the objects providing locale sensitive services, Collator, NumberFormat, DateTimeFormat, PluralRules, and RelativeTimeFormat, use a common pattern to negotiate the requests represented by the locales and options arguments against the actual capabilities of their implementations. The common behaviour is described here in terms of internal slots describing the capabilities and of abstract operations using these internal slots.

#### 9.1 Internal slots of Service Constructors

- `[[AvailableLocales]]` is a List that contains structurally valid (6.2.2) and canonicalized (6.2.3) Unicode BCP 47 locale identifiers identifying the locales for which the implementation provides the functionality of the constructed objects. Language tags on the list must not have a Unicode locale extension sequence. The list must include the value returned by the DefaultLocale abstract operation (6.2.4), and must not include duplicates. Implementations must include in `[[AvailableLocales]]` locales that can serve as fallbacks in the algorithm used to resolve locales (see 9.2.7). For example, implementations that provide a "de-DE" locale must include a "de" locale that can serve as a fallback for requests such as "de-AT" and "de-CH". For locales that include a script subtag in addition to language and region, the corresponding locale without a script subtag must also be supported; that is, if an implementation recognizes "zh-Hant-TW", it is also expected to recognize "zh-TW". The ordering of the locales within `[[AvailableLocales]]` is irrelevant.

- `[[RelevantExtensionKeys]]` is a List of keys of the language tag extensions defined in Unicode Technical Standard 35 that are relevant for the functionality of the constructed objects.

- `[[SortLocaleData]]` and `[[SearchLocaleData]]` (for Intl.Collator) and `[[LocaleData]]` (for Intl.DateTimeFormat, Intl.DisplayNames, Intl.ListFormat, Intl.NumberFormat, Intl.PluralRules, and Intl.RelativeTimeFormat) are records that have fields for each locale contained in `[[AvailableLocales]]`. The value of each of these fields must be a record that has fields for each key contained in `[[RelevantExtensionKeys]]`. The value of each of these fields must be a non-empty list of those values defined in Unicode Technical Standard 35 for the given key that are supported by the implementation for the given locale, with the first element providing the default value.

**NOTE** For example, an implementation of DateTimeFormat might include the language tag "th" in its `[[AvailableLocales]]` internal slot, and must (according to 11.3.3) include the key "ca" in its `[[RelevantExtensionKeys]]` internal slot. For Thai, the "buddhist" calendar is usually the default, but an implementation might also support the calendars "gregory", "chinese", and "islamic" for the locale "th". The `[[LocaleData]]` internal slot would therefore at least include `[[[th]]: {[cal]: « "buddhist", "gregory", "chinese", "islamic" »}]].

### 9.2 Abstract Operations

© Ecma International
Where the following abstract operations take an `availableLocales` argument, it must be an `[[AvailableLocales]]` List as specified in 9.1.

### 9.2.1 CanonicalizeLocaleList (locales)

The abstract operation `CanonicalizeLocaleList` takes the following steps:

1. If `locales` is `undefined`, then
   a. Return a new empty `List`.
2. Let `seen` be a new empty `List`.
3. If `Type(locales)` is String or `Type(locales)` is Object and `locales` has an `[[InitializedLocale]]` internal slot, then
   a. Let `O` be `CreateArrayFromList(« locales »)`.
4. Else,
   a. Let `O` be `ToObject(locales)`.
5. Let `len` be `? ToLength(? Get(O, "length"))`.
6. Let `k` be 0.
7. Repeat, while `k < len`,
   a. Let `Pk` be `ToString(k)`.
   b. Let `kPresent` be `? HasProperty(O, Pk)`.
   c. If `kPresent` is `true`, then
      i. Let `kValue` be `? Get(O, Pk)`.
      ii. If `Type(kValue)` is not String or Object, throw a `TypeError` exception.
      iii. If `Type(kValue)` is Object and `kValue` has an `[[InitializedLocale]]` internal slot, then
         1. Let `tag` be `kValue.[[Locale]]`.
      iv. Else,
         1. Let `tag` be `? ToString(kValue)`.
      v. If `IsStructurallyValidLanguageTag(tag)` is `false`, throw a `RangeError` exception.
     vi. Let `canonicalizedTag` be `CanonicalizeUnicodeLocaleId(tag)`.
     vii. If `canonicalizedTag` is not an element of `seen`, append `canonicalizedTag` as the last element of `seen`.
   d. Increase `k` by 1.
8. Return `seen`.

**NOTE 1**

Non-normative summary: The abstract operation interprets the `locales` argument as an array and copies its elements into a `List`, validating the elements as structurally valid language tags and canonicalizing them, and omitting duplicates.

**NOTE 2**

Requiring `kValue` to be a String or Object means that the `Number` value `NaN` will not be interpreted as the language tag "nan", which stands for Min Nan Chinese.

### 9.2.2 BestAvailableLocale (availableLocales, locale)

The `BestAvailableLocale` abstract operation compares the provided argument `locale`, which must be a String value with a structurally valid and canonicalized Unicode BCP 47 locale identifier, against the locales in `availableLocales` and returns either the longest non-empty prefix of `locale` that is an element of `availableLocales`, or `undefined` if there is no such element. It uses the fallback mechanism of RFC 4647, section 3.4. The following steps are taken:

1. Let `candidate` be `locale`.
2. Repeat,
   a. If `availableLocales` contains an element equal to `candidate`, return `candidate`.
b. Let \(pos\) be the character index of the last occurrence of "-" (U+002D) within \(candidate\). If that character does not occur, return \(undefined\).
c. If \(pos \geq 2\) and the character "]" occurs at index \(pos-2\) of \(candidate\), decrease \(pos\) by 2.
d. Let \(candidate\) be the substring of \(candidate\) from position 0, inclusive, to position \(pos\), exclusive.

9.2.3 LookupMatcher ( \(availableLocales, requestedLocales\) )

The LookupMatcher abstract operation compares \(requestedLocales\), which must be a List as returned by CanonicalizeLocaleList, against the locales in \(availableLocales\) and determines the best available language to meet the request. The following steps are taken:

1. Let \(result\) be a new Record.
2. For each element \(locale\) of \(requestedLocales\), do
   a. Let \(noExt\) be the String value that is \(locale\) with all Unicode locale extension sequences removed.
   b. Let \(availableLocale\) be \(BestAvailableLocale(availableLocales, noExt)\).
   c. If \(availableLocale\) is not \(undefined\), then
      i. Set \(result.[[locale]]\) to \(availableLocale\).
      ii. If \(locale\) and \(noExt\) are not the same String value, then
         1. Let \(extension\) be the String value consisting of the first substring of \(locale\) that is a Unicode locale extension sequence.
         2. Set \(result.[[extension]]\) to \(extension\).
      iii. Return \(result\).
3. Let \(defLocale\) be DefaultLocale().
4. Set \(result.[[locale]]\) to \(defLocale\).
5. Return \(result\).

NOTE The algorithm is based on the Lookup algorithm described in RFC 4647 section 3.4, but options specified through Unicode locale extension sequences are ignored in the lookup. Information about such subsequences is returned separately. The abstract operation returns a record with a [[locale]] field, whose value is the language tag of the selected locale, which must be an element of \(availableLocales\). If the language tag of the request locale that led to the selected locale contained a Unicode locale extension sequence, then the returned record also contains an [[extension]] field whose value is the first Unicode locale extension sequence within the request locale language tag.

9.2.4 BestFitMatcher ( \(availableLocales, requestedLocales\) )

The BestFitMatcher abstract operation compares \(requestedLocales\), which must be a List as returned by CanonicalizeLocaleList, against the locales in \(availableLocales\) and determines the best available language to meet the request. The algorithm is implementation dependent, but should produce results that a typical user of the requested locales would perceive as at least as good as those produced by the LookupMatcher abstract operation. Options specified through Unicode locale extension sequences must be ignored by the algorithm. Information about such subsequences is returned separately. The abstract operation returns a record with a [[locale]] field, whose value is the language tag of the selected locale, which must be an element of \(availableLocales\). If the language tag of the request locale that led to the selected locale contained a Unicode locale extension sequence, then the returned record also contains an [[extension]] field whose value is the first Unicode locale extension sequence within the request locale language tag.

9.2.5 UnicodeExtensionComponents ( \(extension\) )
The UnicodeExtensionComponents abstract operation returns the attributes and keywords from extension, which must be a String value whose contents are a Unicode locale extension sequence. If an attribute or a keyword occurs multiple times in extension, only the first occurrence is returned. The following steps are taken:

1. Let attributes be a new empty List.
2. Let keywords be a new empty List.
3. Let keyword be undefined.
4. Let size be the length of extension.
5. Let k be 3.
6. Repeat, while k < size,
   a. Let e be ! StringIndexOf(extension, ",", k).
   b. If e = -1, let len be size - k; else let len be e - k.
   c. Let subtag be the String value equal to the substring of extension consisting of the code units at indices k (inclusive) through k + len (exclusive).
   d. If keyword is undefined and len ≠ 2, then
      i. If subtag is not an element of attributes, then
         1. Append subtag to attributes.
   e. Else if len = 2, then
      i. If keyword is not undefined and keywords does not contain an element whose [[Key]] is the same as keyword.[[Key]], then
         1. Append keyword to keywords.
      ii. Set keyword to the Record { [[Key]]: subtag, [[Value]]: ":" }.
   f. Else,
      i. If keyword.[[Value]] is the empty String, then
         1. Set keyword.[[Value]] to subtag.
      ii. Else,
         1. Set keyword.[[Value]] to the string-concatenation of keyword.[[Value]], ",", and subtag.
   g. Let k be k + len + 1.
7. If keyword is not undefined and keywords does not contain an element whose [[Key]] is the same as keyword.[[Key]], then
   a. Append keyword to keywords.
8. Return the Record { [[Attributes]]: attributes, [[Keywords]]: keywords }.

9.2.6 InsertUnicodeExtensionAndCanonicalize ( locale, extension )

The InsertUnicodeExtensionAndCanonicalize abstract operation inserts extension, which must be a Unicode locale extension sequence, into locale, which must be a String value with a structurally valid and canonicalized Unicode BCP 47 locale identifier. The following steps are taken:

The following algorithm refers to UTS 35’s Unicode Language and Locale Identifiers grammar.

1. Assert: locale does not contain a substring that is a Unicode locale extension sequence.
2. Assert: extension is a Unicode locale extension sequence.
3. Assert: tag matches the unicode_locale_id production.
4. Let privateIndex be ! StringIndexOf(locale, ",x-", 0).
5. If privateIndex = -1, then
   a. Let locale be the string-concatenation of locale and extension.
6. Else,
   a. Let preExtension be the substring of locale from position 0, inclusive, to position privateIndex, exclusive.
   b. Let postExtension be the substring of locale from position privateIndex to the end of the string.
   c. Let locale be the string-concatenation of preExtension, extension, and postExtension.
7. Assert: IsStructurallyValidLanguageTag(locale) is true.
8. Return ! CanonicalizeUnicodeLocaleId(locale).

## 9.2.7 ResolveLocale (availableLocales, requestedLocales, options, relevantExtensionKeys, localeData)

The ResolveLocale abstract operation compares a BCP 47 language priority list requestedLocales against the locales in availableLocales and determines the best available language to meet the request. availableLocales, requestedLocales, and relevantExtensionKeys must be provided as List values, options and localeData as Records.

The following steps are taken:

1. Let matcher be options.[localeMatcher].
2. If matcher is "lookup", then
   a. Let r be LookupMatcher(availableLocales, requestedLocales).
3. Else,
   a. Let r be BestFitMatcher(availableLocales, requestedLocales).
4. Let foundLocale be r.[locale].
5. Let result be a new Record.
6. Set result.[dataLocale] to foundLocale.
7. If r has an [[extension]] field, then
   a. Let components be ! UnicodeExtensionComponents(r.[extension]).
   b. Let keywords be components.[Keywords].
8. Let supportedExtension be "-u".
9. For each element key of relevantExtensionKeys, do
   a. Let foundLocaleData be localeData.[<foundLocale>].
   b. Assert: Type(foundLocaleData) is Record.
   c. Let keyLocaleData be foundLocaleData.[<key>].
   d. Assert: Type(keyLocaleData) is List.
   e. Let value be keyLocaleData[0].
   f. Assert: Type(value) is either String or Null.
   g. Let supportedExtensionAddition be "".
   h. If r has an [[extension]] field, then
      i. If keywords contains an element whose [[Key]] is the same as key, then
         1. Let entry be the element of keywords whose [[Key]] is the same as key.
         2. Let requestedValue be entry.[Value].
         3. If requestedValue is not the empty String, then
            a. If keyLocaleData contains requestedValue, then
               i. Let value be requestedValue.
               ii. Let supportedExtensionAddition be the string-concatenation of ";", key, ";", and value.
      4. Else if keyLocaleData contains "true", then
         a. Let value be "true".
         b. Let supportedExtensionAddition be the string-concatenation of ";" and key.
      i. If options has a field [[<key>]], then
         i. Let optionsValue be options.[<key>].
         ii. Assert: Type(optionsValue) is either String, Undefined, or Null.
         iii. If Type(optionsValue) is String, then
               1. Let optionsValue be the string optionsValue after performing the algorithm steps to transform Unicode extension values to canonical syntax per Unicode Technical Standard #35 LDML § 3.2.1 Canonical Unicode Locale Identifiers, treating key as ukey and optionsValue as uvalue productions.
2. Let \( \text{optionsValue} \) be the string \( \text{optionsValue} \) after performing the algorithm steps to replace Unicode extension values with their canonical form per Unicode Technical Standard #35 LDML § 3.2.1 Canonical Unicode Locale Identifiers, treating \( \text{key} \) as \( \text{ukey} \) and \( \text{optionsValue} \) as \( \text{uvalue} \) productions.

3. If \( \text{optionsValue} \) is the empty String, then
   a. Let \( \text{optionsValue} \) be "true".
   iv. If \( \text{keyLocaleData} \) contains \( \text{optionsValue} \), then
      1. If \( \text{SameValue(\( \text{optionsValue}, \text{value} \))} \) is false, then
         a. Let \( \text{value} \) be \( \text{optionsValue} \).
         b. Let \( \text{supportedExtensionAddition} \) be "".
      j. Set \( \text{result.}[\text{locale}] \) to \( \text{value} \).
      k. Append \( \text{supportedExtensionAddition} \) to \( \text{supportedExtension} \).
   10. If the number of elements in \( \text{supportedExtension} \) is greater than 2, then
      a. Let \( \text{foundLocale} \) be \( \text{InsertUnicodeExtensionAndCanonicalize(} \text{foundLocale, supportedExtension}) \).
      11. Set \( \text{result.}[\text{locale}] \) to \( \text{foundLocale} \).
      12. Return \( \text{result} \).

**NOTE** Non-normative summary: Two algorithms are available to match the locales: the Lookup algorithm described in RFC 4647 section 3.4, and an implementation dependent best-fit algorithm. Independent of the locale matching algorithm, options specified through Unicode locale extension sequences are negotiated separately, taking the caller's relevant extension keys and locale data as well as client-provided options into consideration. The abstract operation returns a record with a [[locale]] field whose value is the language tag of the selected locale, and fields for each key in \( \text{relevantExtensionKeys} \) providing the selected value for that key.

### 9.2.8 LookupSupportedLocales (availableLocales, requestedLocales)

The LookupSupportedLocales abstract operation returns the subset of the provided BCP 47 language priority list \( \text{requestedLocales} \) for which \( \text{availableLocales} \) has a matching locale when using the BCP 47 Lookup algorithm. Locales appear in the same order in the returned list as in \( \text{requestedLocales} \). The following steps are taken:

1. Let \( \text{subset} \) be a new empty List.
2. For each element \( \text{locale} \) of \( \text{requestedLocales} \), do
   a. Let \( \text{noExtensionsLocale} \) be the String value that is \( \text{locale} \) with all Unicode locale extension sequences removed.
   b. Let \( \text{availableLocale} \) be \( \text{BestAvailableLocale(} \text{availableLocales, noExtensionsLocale}) \).
   c. If \( \text{availableLocale} \) is not undefined, append \( \text{locale} \) to the end of \( \text{subset} \).
3. Return \( \text{subset} \).

### 9.2.9 BestFitSupportedLocales (availableLocales, requestedLocales)

The BestFitSupportedLocales abstract operation returns the subset of the provided BCP 47 language priority list \( \text{requestedLocales} \) for which \( \text{availableLocales} \) has a matching locale when using the Best Fit Matcher algorithm. Locales appear in the same order in the returned list as in \( \text{requestedLocales} \). The steps taken are implementation dependent.

### 9.2.10 SupportedLocales (availableLocales, requestedLocales, options)

The SupportedLocales abstract operation returns the subset of the provided BCP 47 language priority list \( \text{requestedLocales} \) for which \( \text{availableLocales} \) has a matching locale. Two algorithms are available to
match the locales: the Lookup algorithm described in RFC 4647 section 3.4, and an implementation dependent best-fit algorithm. Locales appear in the same order in the returned list as in requestedLocales. The following steps are taken:

1. Set options to ? CoerceOptionsToObject(options).
3. If matcher is "best fit", then
   a. Let supportedLocales be BestFitSupportedLocales(availableLocales, requestedLocales).
4. Else,
   a. Let supportedLocales be LookupSupportedLocales(availableLocales, requestedLocales).
5. Return CreateArrayFromList(supportedLocales).

9.2.11 GetOptionsObject ( options )

The abstract operation GetOptionsObject returns an Object suitable for use with GetOption, either options itself or a default empty Object. It throws a TypeError if options is not undefined and not an Object.

1. If options is undefined, then
   a. Return ! OrdinaryObjectCreate(null).
2. If Type(options) is Object, then
   a. Return options.
3. Throw a TypeError exception.

9.2.12 CoerceOptionsToObject ( options )

The abstract operation CoerceOptionsToObject coerces options into an Object suitable for use with GetOption, defaulting to an empty Object. Because it coerces non-null primitive values into objects, its use is discouraged for new functionality in favour of GetOptionsObject.

1. If options is undefined, then
   a. Return ! OrdinaryObjectCreate(null).
2. Return ? ToObject(options).

9.2.13 GetOption ( options, property, type, values, fallback )

The abstract operation GetOption extracts the value of the property named property from the provided options object, converts it to the required type, checks whether it is one of a List of allowed values, and fills in a fallback value if necessary. If values is undefined, there is no fixed set of values and any is permitted.

1. Assert: Type(options) is Object.
2. Let value be ? Get(options, property).
3. If value is undefined, return fallback.
4. Assert: type is "boolean" or "string".
5. If type is "boolean", then
   a. Let value be ! ToBoolean(value).
6. If type is "string", then
   a. Let value be ? ToString(value).
7. If values is not undefined and values does not contain an element equal to value, throw a RangeError exception.
8. Return value.

9.2.14 DefaultNumberOption ( value, minimum, maximum, fallback )
The abstract operation DefaultNumberOption converts value to a Number value, checks whether it is in the allowed range, and fills in a fallback value if necessary.

1. If value is undefined, return fallback.
2. Let value be ? ToNumber(value).
3. If value is NaN or less than minimum or greater than maximum, throw a RangeError exception.
4. Return floor(value).

9.2.15 GetNumberOption (options, property, minimum, maximum, fallback)

The abstract operation GetNumberOption extracts the value of the property named property from the provided options object, converts it to a Number value, checks whether it is in the allowed range, and fills in a fallback value if necessary.

1. Assert: Type(options) is Object.
2. Let value be ? Get(options, property).
3. Return ? DefaultNumberOption(value, minimum, maximum, fallback).

9.2.16 PartitionPattern (pattern)

The PartitionPattern abstract operation is called with argument pattern. This abstract operation parses an abstract pattern string into a list of Records with two fields, [[Type]] and [[Value]]. The [[Value]] field will be a String value if [[Type]] is "literal", and undefined otherwise. The syntax of the abstract pattern strings is an implementation detail and is not exposed to users of ECMA-402. The following steps are taken:

1. Let result be a new empty List.
2. Let beginIndex be ! StringIndexOf(pattern, "\{", 0).
3. Let endIndex be 0.
4. Let nextIndex be 0.
5. Let length be the number of code units in pattern.
6. Repeat, while beginIndex is an integer index into pattern,
   a. Set endIndex to ! StringIndexOf(pattern, "\}", beginIndex).
   b. Assert: endIndex is greater than beginIndex.
   c. If beginIndex is greater than nextIndex, then
      i. Let literal be a substring of pattern from position nextIndex, inclusive, to position beginIndex, exclusive.
      ii. Append a new Record { [[Type]]: "literal", [[Value]]: literal } as the last element of the list result.
   d. Let p be the substring of pattern from position beginIndex, exclusive, to position endIndex, exclusive.
   e. Append a new Record { [[Type]]: p, [[Value]]: undefined } as the last element of the list result.
   f. Set nextIndex to endIndex + 1.
   g. Set beginIndex to ! StringIndexOf(pattern, "\", nextIndex).
7. If nextIndex is less than length, then
   a. Let literal be the substring of pattern from position nextIndex, inclusive, to position length, exclusive.
   b. Append a new Record { [[Type]]: "literal", [[Value]]: literal } as the last element of the list result.
8. Return result.

10 Collator Objects
10.1 The Intl.Collator Constructor

The Intl.Collator constructor is the %Collator% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

10.1.1 InitializeCollator (collator, locales, options)

The abstract operation InitializeCollator accepts the arguments collator (which must be an object), locales, and options. It initializes collator as a Collator object. The following steps are taken:

The following algorithm refers to the type nonterminal from UTS 35's Unicode Locale Identifier grammar.

1. Let requestedLocales be ? CanonicalizeLocaleList(locales).
2. Set options to ? CoerceOptionsToObject(options).
4. Set collator.[[Usage]] to usage.
5. If usage is "sort", then
   a. Let localeData be %Collator%.[[SortLocaleData]].
6. Else,
   a. Let localeData be %Collator%.[[SearchLocaleData]].
7. Let opt be a new Record.
9. Set opt.[[localeMatcher]] to matcher.
11. If collation is not undefined, then
   a. If collation does not match the Unicode Locale Identifier type nonterminal, throw a RangeError exception.
12. Set opt.[[co]] to collation.
14. If numeric is not undefined, then
   a. Let numeric be ! ToString(numeric).
15. Set opt.[[kn]] to numeric.
   b. Set opt.[[kf]] to caseFirst.
17. Let relevantExtensionKeys be %Collator%.[[RelevantExtensionKeys]].
18. Let r be ResolveLocale(%Collator%.[[AvailableLocales]], requestedLocales, opt, relevantExtensionKeys, localeData).
19. Set collator.[[Locale]] to r.[[locale]].
20. Let collation be r.[[co]].
21. If collation is null, let collation be "default".
22. Set collator.[[Collation]] to collation.
23. If relevantExtensionKeys contains "kn", then
   a. Set collator.[[Numeric]] to ! SameValue(r.[[kn]], "true").
24. If relevantExtensionKeys contains "kf", then
   a. Set collator.[[CaseFirst]] to r.[[kf]].
25. If sensitivity is undefined, then
   a. If usage is "sort", then
      i. Let sensitivity be "variant".
   b. Else,
      i. Let dataLocale be r.[[dataLocale]].
      ii. Let dataLocaleData be localeData.[[<dataLocale>]].
iii. Let sensitivity be dataLocaleData.[[sensitivity]].
28. Set collator.[[Sensitivity]] to sensitivity.
30. Set collator.[[IgnorePunctuation]] to ignorePunctuation.
31. Return collator.

10.1.2 Intl.Collator ([ locales [, options ] ])

When the Intl.Collator function is called with optional arguments locales and options, the following steps are taken:

1. If NewTarget is undefined, let newTarget be the active function object, else let newTarget be NewTarget.
2. Let internalSlotsList be « [[InitializedCollator]], [[Locale]], [[Usage]], [[Sensitivity]], [[IgnorePunctuation]], [[Collation]], [[BoundCompare]] ».
3. If %Collator%.[[RelevantExtensionKeys]] contains "kn", then
   a. Append [[Numeric]] as the last element of internalSlotsList.
4. If %Collator%.[[RelevantExtensionKeys]] contains "kf", then
   a. Append [[CaseFirst]] as the last element of internalSlotsList.
5. Let collator be ? OrdinaryCreateFromConstructor(newTarget, "%Collator.prototype%c", internalSlotsList).

10.2 Properties of the Intl.Collator Constructor

The Intl.Collator constructor has the following properties:

10.2.1 Intl.Collator.prototype

The value of Intl.Collator.prototype is %Collator.prototype%. This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

10.2.2 Intl.Collator.supportedLocalesOf ( locales [, options ] )

When the supportedLocalesOf method is called with arguments locales and options, the following steps are taken:

1. Let availableLocales be %Collator%.[[AvailableLocales]].
2. Let requestedLocales be ? CanonicalizeLocaleList(locales).

The value of the "length" property of the supportedLocalesOf method is 1.

10.2.3 Internal Slots

The value of the [[AvailableLocales]] internal slot is implementation-defined within the constraints described in 9.1. The value of the [[RelevantExtensionKeys]] internal slot is a List that must include the element "co", may include any or all of the elements "kf" and "kn", and must not include any other elements.

NOTE Unicode Technical Standard 35 describes ten locale extension keys that are relevant to collation: "co" for collator usage and specializations, "ka" for alternate handling, "kb" for backward second level weight, "kc" for case level, "kf" for case
The values of the [[SortLocaleData]] and [[SearchLocaleData]] internal slots are implementation-defined within the constraints described in 9.1 and the following additional constraints, for all locale values `locale`:

- The first element of `[[SortLocaleData]][[locale]].[[co]]` and `[[SearchLocaleData]][[locale]].[[co]]` must be `null`.
- The values "standard" and "search" must not be used as elements in any `[[SortLocaleData]][[locale]].[[co]]` and `[[SearchLocaleData]][[locale]].[[co]]` list.
- `[[SortLocaleData]][[locale]].[[co]]` must have a `[[sensitivity]]` field with a String value equal to "base", "accent", "case", or "variant".

### 10.3 Properties of the Intl.Collator Prototype Object

The Intl.Collator prototype object is itself an ordinary object. `%Collator.prototype%` is not an Intl.Collator instance and does not have an `[[InitializedCollator]]` internal slot or any of the other internal slots of Intl.Collator instance objects.

#### 10.3.1 Intl.Collator.prototype.constructor

The initial value of `Intl.Collator.prototype.constructor` is the intrinsic object `%Collator%`.

#### 10.3.2 Intl.Collator.prototype [ @@toStringTag ]

The initial value of the `@@toStringTag` property is the String value "Intl.Collator".

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

#### 10.3.3 get Intl.Collator.prototype.compare

This named accessor property returns a function that compares two strings according to the sort order of this Collator object.

Intl.Collator.prototype.compare is an accessor property whose set accessor function is `undefined`. Its get accessor function performs the following steps:

1. Let `collator` be the `this` value.
3. If `collator.([[BoundCompare]])` is `undefined`, then
   a. Let `F` be a new built-in function object as defined in 10.3.3.1.
   b. Set `F.([Collator])` to `collator`.
   c. Set `collator.([[BoundCompare]])` to `F`.
4. Return `collator.([[BoundCompare]])`.

**NOTE**

The returned function is bound to `collator` so that it can be passed directly to...
10.3.3.1 Collator Compare Functions

A Collator compare function is an anonymous built-in function that has a [[Collator]] internal slot.

When a Collator compare function \( F \) is called with arguments \( x \) and \( y \), the following steps are taken:

1. Let \( \text{collator} \) be \( F.\text{[[Collator]]} \).
2. Assert: Type(\( \text{collator} \)) is Object and \( \text{collator} \) has an [[InitializedCollator]] internal slot.
3. If \( x \) is not provided, let \( x \) be undefined.
4. If \( y \) is not provided, let \( y \) be undefined.
5. Let \( X \) be ? ToString(\( x \)).
6. Let \( Y \) be ? ToString(\( y \)).
7. Return CompareStrings(\( \text{collator} \), \( x \), \( y \)).

The "length" property of a Collator compare function is 2.

10.3.3.2 CompareStrings ( \( \text{collator} \), \( x \), \( y \) )

When the CompareStrings abstract operation is called with arguments \( \text{collator} \) (which must be an object initialized as a Collator), \( x \) and \( y \) (which must be String values), it returns a Number other than NaN that represents the result of a locale-sensitive String comparison of \( x \) with \( y \). The two Strings are compared in an implementation-defined fashion. The result is intended to order String values in the sort order specified by the effective locale and collation options computed during construction of \( \text{collator} \), and will be negative, zero, or positive, depending on whether \( x \) comes before \( y \) in the sort order, the Strings are equal under the sort order, or \( x \) comes after \( y \) in the sort order, respectively. String values must be interpreted as UTF-16 code unit sequences, and a surrogate pair (a code unit in the range 0xD800 to 0xDBFF followed by a code unit in the range 0xDC00 to 0xDFFF) within a string must be interpreted as the corresponding code point.

The sensitivity of \( \text{collator} \) is interpreted as follows:

- base: Only strings that differ in base letters compare as unequal. Examples: \( a \neq b \), \( a = \dot{a} \), \( a = A \).
- accent: Only strings that differ in base letters or accents and other diacritic marks compare as unequal. Examples: \( a \neq b \), \( a = \dot{a} \), \( a = A \).
- case: Only strings that differ in base letters or case compare as unequal. Examples: \( a \neq b \), \( a = \dot{a} \), \( a = A \).
- variant: Strings that differ in base letters, accents and other diacritic marks, or case compare as unequal. Other differences may also be taken into consideration. Examples: \( a \neq b \), \( a = \dot{a} \), \( a = A \).

NOTE 1 In some languages, certain letters with diacritic marks are considered base letters. For example, in Swedish, "ö" is a base letter that's different from "o".

If the collator is set to ignore punctuation, then strings that differ only in punctuation compare as equal.

For the interpretation of options settable through extension keys, see Unicode Technical Standard 35.

The CompareStrings abstract operation with any given \( \text{collator} \) argument, if considered as a function of the remaining two arguments \( x \) and \( y \), must be a consistent comparison function (as defined in ES2021, 22.1.3.27) on the set of all Strings.

The actual return values are implementation-defined to permit implementers to encode additional information in the value. The method is required to return +0𝔽 when comparing Strings that are considered canonically equivalent by the Unicode standard.
NOTE 2  It is recommended that the CompareStrings abstract operation be implemented following Unicode Technical Standard 10, Unicode Collation Algorithm (available at https://unicode.org/reports/tr10/), using tailorings for the effective locale and collation options of `collator`. It is recommended that implementations use the tailorings provided by the Common Locale Data Repository (available at http://cldr.unicode.org).

NOTE 3  Applications should not assume that the behaviour of the CompareStrings abstract operation for Collator instances with the same resolved options will remain the same for different versions of the same implementation.

10.3.4 Intl.Collator.prototype.resolvedOptions ()

This function provides access to the locale and collation options computed during initialization of the object.

1. Let `collator` be the `this` value.
3. Let `options` be `! OrdinaryObjectCreate(%Object.prototype%).`
4. For each row of Table 3, except the header row, in table order, do
   a. Let `p` be the Property value of the current row.
   b. Let `v` be the value of `collator`'s internal slot whose name is the Internal Slot value of the current row.
   c. If the current row has an Extension Key value, then
      i. Let `extensionKey` be the Extension Key value of the current row.
      ii. If `%Collator%.[[RelevantExtensionKeys]]` does not contain `extensionKey`, then
         1. Let `v` be `undefined`.
   d. If `v` is not `undefined`, then
      i. Perform ! CreateDataPropertyOrThrow(`options`, `p`, `v`).
5. Return `options`.

Table 3: Resolved Options of Collator Instances

10.4 Properties of Intl.Collator Instances

Intl.Collator instances are ordinary objects that inherit properties from `%Collator.prototype%.

Intl.Collator instances have an `[[InitializedCollator]]` internal slot.

Intl.Collator instances also have several internal slots that are computed by the constructor:
• [[Locale]] is a String value with the language tag of the locale whose localization is used for collation.
• [[Usage]] is one of the String values "sort" or "search", identifying the collator usage.
• [[Sensitivity]] is one of the String values "base", "accent", "case", or "variant", identifying the collator's sensitivity.
• [[IgnorePunctuation]] is a Boolean value, specifying whether punctuation should be ignored in comparisons.
• [[Collation]] is a String value with the "type" given in Unicode Technical Standard 35 for the collation, except that the values "standard" and "search" are not allowed, while the value "default" is allowed.

Intl.Collator instances also have the following internal slots if the key corresponding to the name of the internal slot in Table 3 is included in the [[RelevantExtensionKeys]] internal slot of Intl.Collator:

• [[Numeric]] is a Boolean value, specifying whether numeric sorting is used.
• [[CaseFirst]] is one of the String values "upper", "lower", or "false".

Finally, Intl.Collator instances have a [[BoundCompare]] internal slot that caches the function returned by the compare accessor (10.3.3).

11 DateTimeFormat Objects

11.1 Abstract Operations for DateTimeFormat Objects

Several DateTimeFormat algorithms use values from the following table, which provides internal slots, property names and allowable values for the components of date and time formats:

<table>
<thead>
<tr>
<th>Internal Slot</th>
<th>Property</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Weekday]]</td>
<td>&quot;weekday&quot;</td>
<td>&quot;narrow&quot;, &quot;short&quot;, &quot;long&quot;</td>
</tr>
<tr>
<td>[[Era]]</td>
<td>&quot;era&quot;</td>
<td>&quot;narrow&quot;, &quot;short&quot;, &quot;long&quot;</td>
</tr>
<tr>
<td>[[Year]]</td>
<td>&quot;year&quot;</td>
<td>&quot;2-digit&quot;, &quot;numeric&quot;</td>
</tr>
<tr>
<td>[[Month]]</td>
<td>&quot;month&quot;</td>
<td>&quot;2-digit&quot;, &quot;numeric&quot;, &quot;narrow&quot;, &quot;short&quot;, &quot;long&quot;</td>
</tr>
<tr>
<td>[[Day]]</td>
<td>&quot;day&quot;</td>
<td>&quot;2-digit&quot;, &quot;numeric&quot;</td>
</tr>
<tr>
<td>[[DayPeriod]]</td>
<td>&quot;dayPeriod&quot;</td>
<td>&quot;narrow&quot;, &quot;short&quot;, &quot;long&quot;</td>
</tr>
<tr>
<td>[[Hour]]</td>
<td>&quot;hour&quot;</td>
<td>&quot;2-digit&quot;, &quot;numeric&quot;</td>
</tr>
<tr>
<td>[[Minute]]</td>
<td>&quot;minute&quot;</td>
<td>&quot;2-digit&quot;, &quot;numeric&quot;</td>
</tr>
<tr>
<td>[[Second]]</td>
<td>&quot;second&quot;</td>
<td>&quot;2-digit&quot;, &quot;numeric&quot;</td>
</tr>
<tr>
<td>[[FractionalSecondDigits]]</td>
<td>&quot;fractionalSecondDigits&quot;</td>
<td>1𝔽, 2𝔽, 3𝔽</td>
</tr>
<tr>
<td>[[TimeZoneName]]</td>
<td>&quot;timeZoneName&quot;</td>
<td>&quot;short&quot;, &quot;long&quot;</td>
</tr>
</tbody>
</table>

11.1.1 InitializeDateTimeFormat (dateTimeFormat, locales, options)

The abstract operation InitializeDateTimeFormat accepts the arguments dateTimeFormat (which must be an object), locales, and options. It initializes dateTimeFormat as a DateTimeFormat object. This abstract
The operation functions as follows:

The following algorithm refers to the **type** nonterminal from UTS 35's Unicode Locale Identifier grammar.

1. Let `requestedLocales` be ? `CanonicalizeLocaleList(locales)`.
2. Let `options` be ? `ToDateTimeOptions(options, "any", "date")`.
3. Let `opt` be a new `Record`.
5. Set `opt.[localeMatcher]` to `matcher`.
7. If `calendar` is not `undefined`, then
   a. If `calendar` does not match the Unicode Locale Identifier **type** nonterminal, throw a `RangeError` exception.
8. Set `opt.[ca]` to `calendar`.
9. Let `numberingSystem` be ? `GetOption(options, "numberingSystem", "string", undefined, undefined)`.
10. If `numberingSystem` is not `undefined`, then
    a. If `numberingSystem` does not match the Unicode Locale Identifier **type** nonterminal, throw a `RangeError` exception.
11. Set `opt.[nu]` to `numberingSystem`.
14. If `hour12` is not `undefined`, then
    a. Let `hourCycle` be `null`.
15. Set `opt.[hc]` to `hourCycle`.
16. Let `localeData` be `%DateTimeFormat%.[LocaleData]`.
17. Let `r` be `ResolveLocale(%DateTimeFormat%.[AvailableLocales], requestedLocales, opt, %DateTimeFormat%.[RelevantExtensionKeys], localeData)`.
19. Let `calendar` be `r.[ca]`.
20. Set `dateTimeFormat.[Calendar]` to `calendar`.
23. Let `dataLocale` be `r.[dataLocale]`.
24. Let `timeZone` be ? `Get(options, "timeZone")`.
25. If `TimeZone` is `undefined`, then
    a. Let `timeZone` be `DefaultTimeZone()`.
26. Else,
    a. Let `timeZone` be ? `ToString(timeZone)`.
    b. If the result of `IsValidTimeZoneName(timeZone)` is `false`, then
       i. Throw a `RangeError` exception.
    c. Let `timeZone` be `CanonicalizeTimeZoneName(timeZone)`.
27. Set `dateTimeFormat.[TimeZone]` to `timeZone`.
28. Let `opt` be a new `Record`.
29. For each row of **Table 4**, except the header row, in table order, do
    a. Let `prop` be the name given in the Property column of the row.
    b. If `prop` is "fractionalSecondDigits", then
       i. Let `value` be ? `GetNumberOption(options, "fractionalSecondDigits", 1, 3, undefined)`.
    c. Else,
       i. Let `value` be ? `GetOption(options, prop, "string", the strings given in the Values column of the row)`, `undefined`.
30. Set `opt.[<prop>]` to `value`.

© Ecma International
30. Let `dataLocaleData` be `localeData. [[<dataLocale>]]`.

32. Let `dateStyle` be `? GetOption(options, "dateStyle", "string", "full", "long", "medium", "short", undefined)`.

33. Set `dateTimeFormat. [[DateStyle]]` to `dateStyle`.

34. Let `timeStyle` be `? GetOption(options, "timeStyle", "string", "full", "long", "medium", "short", undefined)`.

35. Set `dateTimeFormat. [[TimeStyle]]` to `timeStyle`.

36. If `dateStyle` is not `undefined` or `timeStyle` is not `undefined`, then
   a. For each row in Table 4, except the header row, do
      i. Let `prop` be the name given in the Property column of the row.
      ii. Let `p` be `opt. [[<prop>]]`.
      iii. If `p` is not `undefined`, then
         1. Throw a `TypeError` exception.
   b. Let `styles` be `dataLocaleData. [[styles]]. [[<calendar>]]`.
   c. Let `bestFormat` be `DateTimeStyleFormat(dateStyle, timeStyle, styles)`.

37. Else,
   a. Let `formats` be `dataLocaleData. [[formats]]. [[<calendar>]]`.
   b. If `matcher` is "basic", then
      i. Let `bestFormat` be `BasicFormatMatcher(opt, formats)`.
   c. Else,
      i. Let `bestFormat` be `BestFitFormatMatcher(opt, formats)`.

38. For each row in Table 4, except the header row, in table order, do
   a. Let `prop` be the name given in the Property column of the row.
   b. If `bestFormat` has a field `[[<prop>]]`, then
      i. Let `p` be `bestFormat. [[<prop>]]`.
      ii. Set `dateTimeFormat`'s internal slot whose name is the Internal Slot column of the row to `p`.

39. If `dateTimeFormat. [[Hour]]` is `undefined`, then
   a. Set `dateTimeFormat. [[HourCycle]]` to `undefined`.
   b. Let `pattern` be `bestFormat. [[pattern]]`.
   c. Let `rangePatterns` be `bestFormat. [[rangePatterns]]`.

40. Else,
   a. Let `hcDefault` be `dataLocaleData. [[hourCycle]]`.
   b. Let `hc` be `dateTimeFormat. [[HourCycle]]`.
   c. If `hc` is `null`, then
      i. Set `hc` to `hcDefault`.
   d. If `hour12` is not `undefined`, then
      i. If `hour12` is `true`, then
         1. If `hcDefault` is "h11" or "h23", then
            a. Set `hc` to "h11".
         2. Else, a. Set `hc` to "h12".
      ii. Else,
         1. Assert: `hour12` is `false`.
         2. If `hcDefault` is "h11" or "h23", then
            a. Set `hc` to "h23".
         3. Else, a. Set `hc` to "h24".
   e. Set `dateTimeFormat. [[HourCycle]]` to `hc`.
   f. If `dateTimeFormat. [[HourCycle]]` is "h11" or "h12", then
      i. Let `pattern` be `bestFormat. [[pattern12]]`.
      ii. Let `rangePatterns` be `bestFormat. [[rangePatterns12]]`.
   g. Else, i. Let `pattern` be `bestFormat. [[pattern]]`.  

© Ecma International
ii. Let rangePatterns be bestFormat.[[rangePatterns]].
41. Set dateTimeFormat.[[Pattern]] to pattern.
42. Set dateTimeFormat.[[RangePatterns]] to rangePatterns.
43. Return dateTimeFormat.

11.1.2 ToDateTimeOptions (options, required, defaults)

When the ToDateTimeOptions abstract operation is called with arguments options, required, and defaults, the following steps are taken:

1. If options is undefined, let options be null; otherwise let options be ? ToObject(options).
2. Let options be OrdinaryObjectCreate(options).
3. Let needDefaults be true.
4. If required is "date" or "any", then
   a. For each of the property names "weekday", "year", "month", "day", do
      i. Let prop be the property name.
      ii. Let value be ? Get(options, prop).
      iii. If value is not undefined, let needDefaults be false.
5. If required is "time" or "any", then
   a. For each of the property names "dayPeriod", "hour", "minute", "second", 
      "fractionalSecondDigits", do
      i. Let prop be the property name.
      ii. Let value be ? Get(options, prop).
      iii. If value is not undefined, let needDefaults be false.
6. Let dateStyle be ? Get(options, "dateStyle").
7. Let timeStyle be ? Get(options, "timeStyle").
8. If dateStyle is not undefined or timeStyle is not undefined, let needDefaults be false.
9. If required is "date" and timeStyle is not undefined, then
   a. Throw a TypeError exception.
10. If required is "time" and dateStyle is not undefined, then
    a. Throw a TypeError exception.
11. If needDefaults is true and defaults is either "date" or "all", then
    a. For each of the property names "year", "month", "day", do
       i. Perform ? CreateDataPropertyOrThrow(options, prop, "numeric").
12. If needDefaults is true and defaults is either "time" or "all", then
    a. For each of the property names "hour", "minute", "second", do
       i. Perform ? CreateDataPropertyOrThrow(options, prop, "numeric").
13. Return options.

11.1.3 DateTimeStyleFormat (dateStyle, timeStyle, styles)

The DateTimeStyleFormat abstract operation accepts arguments dateStyle and timeStyle, which are each either undefined, "full", "long", "medium", or "short", at least one of which is not undefined, and styles, which is a record from %DateTimeFormat%.[[LocaleData]][[locale]][[styles]][calendar] for some locale locale and calendar calendar. It returns the appropriate format record for date time formatting based on the parameters.

1. If timeStyle is not undefined, then
   a. Assert: timeStyle is one of "full", "long", "medium", or "short".
   b. Let timeFormat be styles.[[TimeFormat]][<timeStyle>]].
2. If dateStyle is not undefined, then
   a. Assert: dateStyle is one of "full", "long", "medium", or "short".
   b. Let dateFormat be styles.[[DateFormat]][<dateStyle>]].
3. If dateStyle is not undefined and timeStyle is not undefined, then
   a. Let format be a new Record.
b. Add to format all fields from dateFormat except [[pattern]] and [[rangePatterns]].
c. Add to format all fields from timeFormat except [[pattern]], [[rangePatterns]],
   [[pattern12]], and [[rangePatterns12]], if present.
d. Let connector be styles.[[DateTimeFormat]].[[<dateStyle>]].
e. Let pattern be the string connector with the substring "[0]" replaced with timeFormat.
   [[pattern]] and the substring "[1]" replaced with dateFormat.[[pattern]].
f. Set format.[[pattern]] to pattern.
g. If timeFormat has a [[pattern12]] field, then
   i. Let pattern12 be the string connector with the substring "[0]" replaced with
      timeFormat.[[pattern12]] and the substring "[1]" replaced with
      dateFormat.[[pattern]].
   ii. Set format.[[pattern12]] to pattern12.

h. Let dateTimeRangeFormat be styles.[[DateTimeRangeFormat]].[[<dateStyle>]].
   [[<timeStyle>]].
i. Set format.[[rangePatterns]] to dateTimeRangeFormat.[[rangePatterns]].

j. If dateTimeRangeFormat has a [[rangePatterns12]] field, then
   i. Set format.[[rangePatterns12]] to dateTimeRangeFormat.[[rangePatterns12]].
k. Return format.

4. If timeStyle is not undefined, then
   a. Return timeFormat.

5. Assert: dateStyle is not undefined.

6. Return dateFormat.

11.1.4 BasicFormatMatcher ( options, formats )

When the BasicFormatMatcher abstract operation is called with two arguments options and formats, the
following steps are taken:

1. Let removalPenalty be 120.
2. Let additionPenalty be 20.
3. Let longLessPenalty be 8.
5. Let shortLessPenalty be 6.
7. Let bestScore be -Infinity.
8. Let bestFormat be undefined.
9. Assert: Type(formats) is List.
10. For each element format of formats, do
    a. Let score be 0.
    b. For each property name property shown in Table 4, do
       i. If options has a field [[<property>]], let optionsProp be options.[[<property>]]; else let
          optionsProp be undefined.
       ii. If format has a field [[<property>]], let formatProp be format.[[<property>]]; else let
           formatProp be undefined.
       iii. If optionsProp is undefined and formatProp is not undefined, decrease score by
            additionPenalty.
       iv. Else if optionsProp is not undefined and formatProp is undefined, decrease score by
            removalPenalty.
       v. Else if optionsProp != formatProp, then
          1. If property is "fractionalSecondDigits", then
             a. Let values be « 1𝔽, 2𝔽, 3𝔽 ».
          2. Else,
             a. Let values be « "2-digit", "numeric", "narrow", "short", "long" ».
       3. Let optionsPropIndex be the index of optionsProp within values.
       4. Let formatPropIndex be the index of formatProp within values.
5. Let \( \delta \) be \( \max(\min(\text{formatPropIndex} - \text{optionsPropIndex}, 2), -2) \).
6. If \( \delta = 2 \), decrease \( \text{score} \) by \( \text{longMorePenalty} \).
7. Else if \( \delta = 1 \), decrease \( \text{score} \) by \( \text{shortMorePenalty} \).
8. Else if \( \delta = -1 \), decrease \( \text{score} \) by \( \text{shortLessPenalty} \).
9. Else if \( \delta = -2 \), decrease \( \text{score} \) by \( \text{longLessPenalty} \).

c. If \( \text{score} > \text{bestScore} \), then
   i. Let \( \text{bestScore} \) be \( \text{score} \).
   ii. Let \( \text{bestFormat} \) be \( \text{format} \).
11. Return \( \text{bestFormat} \).

### 11.1.5 BestFitFormatMatcher ( options, formats )

When the BestFitFormatMatcher abstract operation is called with two arguments \( \text{options} \) and \( \text{formats} \), it performs implementation dependent steps, which should return a set of component representations that a typical user of the selected locale would perceive as at least as good as the one returned by BasicFormatMatcher.

### 11.1.6 DateTime Format Functions

A DateTime format function is an anonymous built-in function that has a \([\text{DateTimeFormat}]\) internal slot.

When a DateTime format function \( F \) is called with optional argument \( \text{date} \), the following steps are taken:

1. Let \( \text{dtf} \) be \( F.\text{[[DateTimeFormat]]} \).
2. Assert: Type(\( \text{dtf} \)) is Object and \( \text{dtf} \) has an \([\text{InitializedDateTimeFormat}]\) internal slot.
3. If \( \text{date} \) is not provided or is \( \text{undefined} \), then
   a. Let \( x \) be \( \text{Call}(\%\text{Date.now}%, \text{undefined}) \).
4. Else,
   a. Let \( x \) be \( \text{? ToNumber}(\text{date}) \).
5. Return \( \text{? FormatDateTime}(\text{dtf}, x) \).

The "length" property of a DateTime format function is 1.

### 11.1.7 FormatDateTimePattern ( date, patternParts, x, rangeFormatOptions )

The FormatDateTimePattern abstract operation is called with arguments \( \text{date} \), \( \text{patternParts} \) (which are a list of Records as returned by PartitionPattern), \( x \) (which must be a Number value), and \( \text{rangeFormatOptions} \) (which is a range pattern Record as used in \([\text{rangePattern}]\) or \( \text{undefined} \)), interprets \( x \) as a time value as specified in ES2021, 20.4.1.1, and creates the corresponding parts according pattern and to the effective locale and the formatting options of \( \text{date} \) and \( \text{rangeFormatOptions} \). The following steps are taken:

1. Let \( x \) be \( \text{TimeClip}(x) \).
2. If \( x \) is \( \text{NaN} \), throw a \( \text{RangeError} \) exception.
3. Let \( \text{locale} \) be \( \text{date.\text{[[Locale]]}} \).
4. Let \( \text{nfOptions} \) be \( \text{OrdinaryObjectCreate}(\text{null}) \).
5. Perform \( \text{! CreateDataPropertyOrThrow}(\text{nfOptions}, \text{"useGrouping"}, \text{false}) \).
6. Let \( \text{nf} \) be \( \text{? Construct}(\%\text{NumberFormat}%, \\text{\{locale, nfOptions\}}) \).
7. Let \( \text{nf2Options} \) be \( \text{OrdinaryObjectCreate}(\text{null}) \).
8. Perform \( \text{! CreateDataPropertyOrThrow}(\text{nf2Options}, \text{"minimumIntegerDigits"}, 2) \).
9. Perform \( \text{! CreateDataPropertyOrThrow}(\text{nf2Options}, \text{"useGrouping"}, \text{false}) \).
10. Let \( \text{nf2} \) be \( \text{? Construct}(\%\text{NumberFormat}%, \\text{\{locale, nf2Options\}}) \).
11. Let \( \text{fractionalSecondDigits} \) be \( \text{date.\text{[[FractionalSecondDigits]]}} \).
12. If \texttt{fractionalSecondDigits} is not \texttt{undefined}, then
   
a. Let \texttt{nf3Options} be \texttt{OrdinaryObjectCreate(null)}.
   
b. Perform \texttt{! CreateDataPropertyOrThrow(nf3Options, "minimumIntegerDigits", 
fractionalSecondDigits)}.
   
c. Perform \texttt{! CreateDataPropertyOrThrow(nf3Options, "useGrouping", false)}.
   
d. Let \texttt{nf3} be \texttt{? Construct(\%NumberFormat\%, \{locale, nf3Options\})}.

13. Let \texttt{tm} be \texttt{ToLocalTime(x, dateTimeFormat.[[Calendar]], dateTimeFormat.[[TimeZone]]).}

14. Let \texttt{result} be a new empty \texttt{List}.

15. For each \texttt{Record \{ [[Type]], [[Value]] \} patternPart in patternParts}, do
   
a. Let \texttt{p} be \texttt{patternPart.[[Type]]}.
   
b. If \texttt{p} is "literal", then
      
i. Append a new \texttt{Record \{ [[Type]]: "literal", [[Value]]: \texttt{patternPart.[[Value]]} \} as the last element of the list \texttt{result}.
   
c. Else if \texttt{p} is equal to "\texttt{fractionalSecondDigits}"}, then
      
i. Let \texttt{v} be \texttt{tm.[[Millisecond]]}.
      
   
   ii. Let \texttt{v} be \texttt{floor(v \times 10^{(\texttt{fractionalSecondDigits} - 3)})}.
      
   
   iii. Let \texttt{fv} be \texttt{FormatNumeric(nf3, v)}.
      
   
   iv. Append a new \texttt{Record \{ [[Type]]: "\texttt{fractionalSecond}" , [[Value]]: \texttt{fv} \} as the last element of \texttt{result}.
   
d. Else if \texttt{p} is equal to "\texttt{dayPeriod}"}, then
      
i. Let \texttt{f} be the value of \texttt{dateTimeFormat}'s internal slot whose name is the Internal Slot column of the matching row.
      
   
   ii. Let \texttt{fv} be a String value representing the day period of \texttt{tm} in the form given by \texttt{f}; the String value depends upon the implementation and the effective locale of \texttt{dateTimeFormat}.
      
   
   iii. Append a new \texttt{Record \{ [[Type]]: \texttt{p}, [[Value]]: \texttt{fv} \} as the last element of the list \texttt{result}.
   
e. Else if \texttt{p} matches a Property column of the row in Table 4, then
      
i. If \texttt{rangeFormatOptions} is not \texttt{undefined}, let \texttt{f} be the value of \texttt{rangeFormatOptions}'s field whose name matches \texttt{p}.
      
   
   ii. Else, let \texttt{f} be the value of \texttt{dateTimeFormat}'s internal slot whose name is the Internal Slot column of the matching row.
      
   
   iii. Let \texttt{v} be the value of \texttt{tm}'s field whose name is the Internal Slot column of the matching row.
      
   
   iv. If \texttt{p} is "\texttt{year}" and \texttt{v} ≤ 0, let \texttt{v} be \texttt{1 - v}.
      
   
   v. If \texttt{p} is "\texttt{month}"}, increase \texttt{v} by 1.
      
   
   vi. If \texttt{p} is "\texttt{hour}" and \texttt{dateTimeFormat.[[HourCycle]]} is "\texttt{h11}" or "\texttt{h12}"}, then
         
   
   1. Let \texttt{v} be \texttt{v modulo 12}.
   
   
   2. If \texttt{v} is 0 and \texttt{dateTimeFormat.[[HourCycle]]} is "\texttt{h12}", let \texttt{v} be 12.
      
   
   vii. If \texttt{p} is "\texttt{hour}" and \texttt{dateTimeFormat.[[HourCycle]]} is "\texttt{h24}"}, then
         
   
   1. If \texttt{v} is 0, let \texttt{v} be 24.
      
   
   viii. If \texttt{f} is "\texttt{numeric}"}, then
           
   
   1. Let \texttt{fv} be \texttt{FormatNumeric(nf, v)}.
           
   
   ix. Else if \texttt{f} is "\texttt{2-digit}"}, then
           
   
   1. Let \texttt{fv} be \texttt{FormatNumeric(nf2, v)}.
           
   
   2. If the "\texttt{length}" property of \texttt{fv} is greater than 2, let \texttt{fv} be the substring of \texttt{fv} containing the last two characters.
      
   
   x. Else if \texttt{f} is "\texttt{narrow}" , "\texttt{short}" , or "\texttt{long}" , then let \texttt{fo} be a String value representing \texttt{v} in the form given by \texttt{f}; the String value depends upon the implementation and the effective locale and calendar of \texttt{dateTimeFormat}. If \texttt{p} is "\texttt{month}" and \texttt{rangeFormatOptions} is \texttt{undefined}, then the String value may also depend on whether \texttt{dateTimeFormat.[[Day]]} is \texttt{undefined}. If \texttt{p} is "\texttt{month}" and \texttt{rangeFormatOptions} is not \texttt{undefined}, then the String value may also depend on whether \texttt{rangeFormatOptions.[[day]]} is \texttt{undefined}. If \texttt{p} is "\texttt{TimeZoneName}"}, then the String value may also depend on the value of the [[InDST]] field of \texttt{tm}. If \texttt{p} is
"era" and `rangeFormatOptions` is `undefined`, then the String value may also depend on whether `dateTimeFormat.[[Era]]` is `undefined`. If `p` is "era" and `rangeFormatOptions` is not `undefined`, then the String value may also depend on whether `rangeFormatOptions.[[era]]` is `undefined`. If the implementation does not have a localized representation of `f`, then use the String value of `v` itself.

xi. Append a new `Record` { [[Type]]: `p`, [[Value]]: `fv` } as the last element of the list `result`.

f. Else if `p` is equal to "ampm", then
   i. Let `v` be `tm`.[[Hour]].
   ii. If `v` is greater than 11, then
      1. Let `fv` be an implementation and locale dependent String value representing "post meridiem".
   iii. Else,
      1. Let `fv` be an implementation and locale dependent String value representing "ante meridiem".
   iv. Append a new `Record` { [[Type]]: "dayPeriod", [[Value]]: `fv` } as the last element of the list `result`.

g. Else if `p` is equal to "relatedYear", then
   i. Let `v` be `tm`.[[RelatedYear]].
   ii. Let `fv` be `FormatNumeric`(nf, v).
   iii. Append a new `Record` { [[Type]]: "relatedYear", [[Value]]: `fv` } as the last element of the list `result`.

h. Else if `p` is equal to "yearName", then
   i. Let `v` be `tm`.[[YearName]].
   ii. Let `fv` be an implementation and locale dependent String value representing `v`.
   iii. Append a new `Record` { [[Type]]: "yearName", [[Value]]: `fv` } as the last element of the list `result`.

i. Else,
   i. Let `unknown` be an implementation-, locale-, and numbering system-dependent String based on `x` and `p`.
   ii. Append a new `Record` { [[Type]]: "unknown", [[Value]]: `unknown` } as the last element of `result`.

16. Return `result`.

NOTE 1 It is recommended that implementations use the locale and calendar dependent strings provided by the Common Locale Data Repository (available at `http://cldr.unicode.org`), and use CLDR "abbreviated" strings for `DateTimeFormat ''short''` strings, and CLDR "wide" strings for `DateTimeFormat ''long''` strings.

NOTE 2 It is recommended that implementations use the time zone information of the IANA Time Zone Database.

11.1.8 PartitionDateTimePattern ( `dateTimeFormat`, `x` )

The PartitionDateTimePattern abstract operation is called with arguments `dateTimeFormat` (which must be an object initialized as a `DateTimeFormat`) and `x` (which must be a `Number value`), interprets `x` as a `time value` as specified in ES2021, 20.4.1.1, and creates the corresponding parts according to the effective locale and the formatting options of `dateTimeFormat`. The following steps are taken:

1. Let `patternParts` be `PartitionPattern`(`dateTimeFormat`.[[Pattern]]).
2. Let `result` be `? FormatDateTimePattern`(`dateTimeFormat`, `patternParts`, `x`, `undefined`).
3. Return `result`. 
11.1.9 FormatDateTime ( `dateTimeFormat, x` )

The FormatDateTime abstract operation is called with arguments `dateTimeFormat` (which must be an object initialized as a DateTimeFormat) and `x` (which must be a Number value), and performs the following steps:

1. Let `parts` be ? PartitionDateTimePattern(`dateTimeFormat, x`).
2. Let `result` be the empty String.
3. For each Record `{ [[Type]], [[Value]] } part in `parts`, do
   a. Set `result` to the string-concatenation of `result` and `part.[[Value]]`.
4. Return `result`.

11.1.10 FormatDateTimeToParts ( `dateTimeFormat, x` )

The FormatDateTimeToParts abstract operation is called with arguments `dateTimeFormat` (which must be an object initialized as a DateTimeFormat) and `x` (which must be a Number value), and performs the following steps:

1. Let `parts` be ? PartitionDateTimePattern(`dateTimeFormat, x`).
2. Let `result` be ArrayCreate(0).
3. Let `n` be 0.
4. For each Record `{ [[Type]], [[Value]] } part in `parts`, do
   a. Let `O` be OrdinaryObjectCreate(%Object.prototype%).
   b. Perform ! CreateDataPropertyOrThrow(`O, "type", part.[[Type]])
   c. Perform ! CreateDataPropertyOrThrow(`O, "value", part.[[Value]])
   d. Perform ! CreateDataProperty(`result, ! ToString(`n), `O)
   e. Increment `n` by 1.
5. Return `result`.

11.1.11 PartitionDateTimeRangePattern ( `dateTimeFormat, x, y` )

The PartitionDateTimeRangePattern abstract operation is called with arguments `dateTimeFormat` (which must be an object initialized as a DateTimeFormat), `x` (which must be a Number value) and `y` (which must be a Number value), interprets `x` and `y` as time values as specified in ES2021, 20.4.1.1, and creates the corresponding parts according to the effective locale and the formatting options of `dateTimeFormat`. The following steps are taken:

1. Let `x` be TimeClip(`x`).
2. If `x` is NaN, throw a RangeError exception.
3. Let `y` be TimeClip(`y`).
4. If `y` is NaN, throw a RangeError exception.
5. If `x` is greater than `y`, throw a RangeError exception.
6. Let `tm1` be ToLocalTime(`x, dateTimeFormat.[[Calendar]], dateTimeFormat.[[TimeZone]])
7. Let `tm2` be ToLocalTime(`y, dateTimeFormat.[[Calendar]], dateTimeFormat.[[TimeZone]])
8. Let `rangePatterns` be `dateTimeFormat.[[RangePatterns]]
9. Let `rangePattern` be undefined.
10. Let `dateFieldsPracticallyEqual` be true.
11. Let `patternContainsLargerDateField` be false.
12. While `dateFieldsPracticallyEqual` is true and `patternContainsLargerDateField` is false, repeat for each row of Table 6 in order, except the header row:
   a. Let `fieldName` be the name given in the Range Pattern Field column of the row.
   b. If `rangePatterns` has a field `[[<fieldName>]]`, let `rp` be `rangePatterns.[[<fieldName>]]`; else let `rp` be undefined.
   c. If `rangePattern` is not undefined and `rp` is undefined, then
      i. Set `patternContainsLargerDateField` to true.
   d. Else,
i. Let $rangePattern$ be $rp$.

ii. If $fieldName$ is equal to $[[\text{AmPm}]]$, then
1. Let $v1$ be $tm1.[[\text{Hour}]]$.
2. Let $v2$ be $tm2.[[\text{Hour}]]$.
3. If $v1$ is greater than 11 and $v2$ less or equal than 11, or $v1$ is less or equal than 11 and $v2$ is greater than 11, then
   a. Set $dateFieldsPracticallyEqual$ to false.

iii. Else if $fieldName$ is equal to $[[\text{DayPeriod}]]$, then
1. Let $v1$ be a String value representing the day period of $tm1$; the String value depends upon the implementation and the effective locale of $dateTimeFormat$.
2. Let $v2$ be a String value representing the day period of $tm2$; the String value depends upon the implementation and the effective locale of $dateTimeFormat$.
3. If $v1$ is not equal to $v2$, then
   a. Set $dateFieldsPracticallyEqual$ to false.

iv. Else if $fieldName$ is equal to $[[\text{FractionalSecondDigits}]]$, then
1. Let $fractionalSecondDigits$ be $dateTimeFormat.[[\text{FractionalSecondDigits}]]$.
2. If $fractionalSecondDigits$ is undefined, then
   a. Set $fractionalSecondDigits$ to 3.
3. Let $v1$ be $tm1.[[\text{Millisecond}]]$.
4. Let $v2$ be $tm2.[[\text{Millisecond}]]$.
5. Let $v1$ be $\text{floor}(v1 \times 10^{(fractionalSecondDigits - 3)})$.
6. Let $v2$ be $\text{floor}(v2 \times 10^{(fractionalSecondDigits - 3)})$.
7. If $v1$ is not equal to $v2$, then
   a. Set $dateFieldsPracticallyEqual$ to false.

v. Else,
1. Let $v1$ be $tm1.[[<fieldName>]]$.
2. Let $v2$ be $tm2.[[<fieldName>]]$.
3. If $v1$ is not equal to $v2$, then
   a. Set $dateFieldsPracticallyEqual$ to false.

13. If $dateFieldsPracticallyEqual$ is true, then
   a. Let $pattern$ be $dateTimeFormat.[[\text{Pattern}]]$.
   b. Let $patternParts$ be $\text{PartitionPattern}(pattern)$.
   c. Let $result$ be $\text{FormatDateTimePattern}(dateTimeFormat, patternParts, x, undefined)$.
   d. For each Record $\{[[\text{Type}]], [[\text{Value}]]\} r$ in $result$, do
      i. Set $r.\text{[Source]}$ to "shared".
   e. Return $result$.

14. Let $result$ be a new empty List.

15. If $rangePattern$ is undefined, then
   a. Let $rangePattern$ be $rangePatterns. [[\text{Default}]]$.

16. For each Record $\{[[\text{Pattern}]], [[\text{Source}]]\} rangePatternPart$ in $rangePattern. [[\text{PatternParts}]]$, do
   a. Let $pattern$ be $rangePatternPart. [[\text{Pattern}]]$.
   b. Let $source$ be $rangePatternPart. [[\text{Source}]]$.
   c. If $source$ is "startRange" or "shared", then
      i. Let $z$ be $x$.
   d. Else,
      i. Let $z$ be $y$.
   e. Let $patternParts$ be $\text{PartitionPattern}(pattern)$.
   f. Let $partResult$ be $\text{FormatDateTimePattern}(dateTimeFormat, patternParts, z, rangePattern)$.
   g. For each Record $\{[[\text{Type}]], [[\text{Value}]]\} r$ in $partResult$, do
      i. Set $r.\text{[Source]}$ to source.
   h. Add all elements in $partResult$ to $result$ in order.

17. Return $result$. 
© Ecma International
11.1.12 FormatDateTimeRange (\( \mathit{dateTimeFormat}, x, y \) )

The FormatDateTimeRange abstract operation is called with arguments \( \mathit{dateTimeFormat} \) (which must be an object initialized as a 
DateTimeFormat), \( x \) (which must be a Number value) and \( y \) (which must be a Number value), and performs the following steps:

1. Let \( \mathit{parts} \) be ? PartitionDateTimeRangePattern(\( \mathit{dateTimeFormat}, x, y \)).
2. Let \( \mathit{result} \) be the empty String.
3. For each Record \([[[\mathit{Type}]], [[\mathit{Value}]], [[\mathit{Source}]]] \) \( \mathit{part} \) in \( \mathit{parts} \), do
   a. Set \( \mathit{result} \) to the string-concatenation of \( \mathit{result} \) and \( \mathit{part}.[[\mathit{Value}]]. \)
4. Return \( \mathit{result} \).

11.1.13 FormatDateTimeRangeToParts (\( \mathit{dateTimeFormat}, x, y \) )

The FormatDateTimeRangeToParts abstract operation is called with arguments \( \mathit{dateTimeFormat} \) (which must be an object initialized as a 
DateTimeFormat), \( x \) (which must be a Number value) and \( y \) (which must be a Number value), and performs the following steps:

1. Let \( \mathit{parts} \) be ? PartitionDateTimeRangePattern(\( \mathit{dateTimeFormat}, x, y \)).
2. Let \( \mathit{result} \) be ArrayCreate(0).
3. Let \( n \) be 0.
4. For each Record \([[[\mathit{Type}]], [[\mathit{Value}]], [[\mathit{Source}]]] \) \( \mathit{part} \) in \( \mathit{parts} \), do
   a. Let \( O \) be OrdinaryObjectCreate(%ObjectPrototype%).
   b. Perform ! CreateDataPropertyOrThrow(\( O \), "type", \( \mathit{part}.[[\mathit{Type}]] \)).
   c. Perform ! CreateDataPropertyOrThrow(\( O \), "value", \( \mathit{part}.[[\mathit{Value}]] \)).
   d. Perform ! CreateDataPropertyOrThrow(\( O \), "source", \( \mathit{part}.[[\mathit{Source}]] \)).
   e. Perform ! CreateDataProperty(\( \mathit{result} \), ! ToString(\( n \)), \( O \)).
   f. Increment \( n \) by 1.
5. Return \( \mathit{result} \).

11.1.14 ToLocalTime (\( t, calendar, timeZone \) )

When the ToLocalTime abstract operation is called with arguments \( t \), \( calendar \), and \( timeZone \), the following steps are taken:

1. Assert: Type(\( t \)) is Number.
2. If \( calendar \) is "gregory", then
   a. Let \( \mathit{timeZoneOffset} \) be the value calculated according to LocalTZA(\( t \), true) where the local 
time zone is replaced with timezone \( timeZone \).
   b. Let \( tz \) be the time value \( t + \mathit{timeZoneOffset} \).
   c. Return a record with fields calculated from \( tz \) according to Table 5.
3. Else,
   a. Return a record with the fields of Column 1 of Table 5 calculated from \( t \) for the given 
\( calendar \) and \( timeZone \). The calculations should use best available information about the 
specified \( calendar \) and \( timeZone \), including current and historical information about time 
zone offsets from UTC and daylight saving time rules.

</tr>
</tbody>
</table>

**NOTE**

It is recommended that implementations use the time zone information of the IANA Time Zone Database.

### 11.1.15 UnwrapDateTimeFormat ( dtf )

The UnwrapDateTimeFormat abstract operation gets the underlying DateTimeFormat operation for various methods which implement ECMA-402 v1 semantics for supporting initializing existing Intl objects.

1. **Assert:** Type(dtf) is Object.

    **NORMATIVE OPTIONAL**

    2. If dtf does not have an [[InitializedDateTimeFormat]] internal slot and ? OrdinaryHasInstance(%DateTimeFormat%, dtf) is true, then
       a. Let dtf be ? Get(dtf, %Intl%.[FallbackSymbol]).

    3. Perform ? RequireInternalSlot(dtf, [[InitializedDateTimeFormat]]).  
    4. Return dtf.

    **NOTE**

    See 8.2 Note 1 for the motivation of the normative optional text.

### 11.2 The Intl.DateTimeFormat Constructor

The Intl.DateTimeFormat constructor is the %DateTimeFormat% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

### 11.2.1 Intl.DateTimeFormat ( [ locales , options ] )
When the `Intl.DateTimeFormat` function is called with optional arguments `locales` and `options`, the following steps are taken:

1. If `NewTarget` is `undefined`, let `newTarget` be the active function object, else let `newTarget` be `NewTarget`.
2. Let `dateFormat` be `???OrdinaryCreateFromConstructor(newTarget, "%DateTimeFormat.prototype%", "[[InitializedDateTimeFormat]], [[Locale]], [[Calendar]], [[NumberingSystem]], [[TimeZone]], [[Weekday]], [[Era]], [[Year]], [[Month]], [[Day]], [[DayPeriod]], [[Hour]], [[Minute]], [[Second]], [[TimeZoneName]], [[HourCycle]], [[Pattern]], [[BoundFormat]] »).
3. Perform `??InitializeDateTimeFormat(dateTimeFormat, locales, options)`.

**NORMATIVE OPTIONAL**

4. Let `this` be the `this` value.
5. If `NewTarget` is `undefined` and `???OrdinaryHasInstance(%DateTimeFormat%, this)` is `true`, then
   a. Perform `??DefinePropertyOrThrow(this, %Intl%.[[FallbackSymbol]], PropertyDescriptor{ [[Value]]: dateTimeFormat, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }).`
   b. Return `this`.
6. Return `dateTimeFormat`.

**NOTE** See 8.2 Note 1 for the motivation of the normative optional text.

### 11.3 Properties of the Intl.DateTimeFormat Constructor

The Intl.DateTimeFormat constructor has the following properties:

#### 11.3.1 Intl.DateTimeFormat.prototype

The value of `Intl.DateTimeFormat.prototype` is `%DateTimeFormat.prototype%`.

This property has the attributes `[[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false`.

#### 11.3.2 Intl.DateTimeFormat.supportedLocalesOf ( locales [, options ] )

When the `supportedLocalesOf` method is called with arguments `locales` and `options`, the following steps are taken:

1. Let `availableLocales` be `%DateTimeFormat%.[[AvailableLocales]].
2. Let `requestedLocales` be `??CanonicalizeLocaleList(locales).
3. Return `??SupportedLocales(availableLocales, requestedLocales, options)`.

The value of the "length" property of the `supportedLocalesOf` method is 1.

#### 11.3.3 Internal slots

The value of the `[[AvailableLocales]]` internal slot is implementation-defined within the constraints described in 9.1.

The value of the `[[RelevantExtensionKeys]]` internal slot is « "ca", "hc", "nu" ». 
NOTE 1 Unicode Technical Standard 35 describes four locale extension keys that are relevant to date and time formatting: "ca" for calendar, "hc" for hour cycle, "nu" for numbering system (of formatted numbers), and "tz" for time zone. 

DateTimeFormat, however, requires that the time zone is specified through the "timeZone" property in the options objects.

The value of the [[LocaleData]] internal slot is implementation-defined within the constraints described in 9.1 and the following additional constraints, for all locale values `locale`:

- `[[LocaleData]][[locale]][[nu]]` must be a List that does not include the values "native", "traditio", or "finance".
- `[[LocaleData]][[locale]][[hc]]` must be `null`, "h11", "h12", "h23", or "h24".
- `[[LocaleData]][[locale]][[hourCycle]]` must be a String value equal to "h11", "h12", "h23", or "h24".
- `[[LocaleData]][[locale]]` must have a `[[formats]]` field. This `[[formats]]` field must be a Record with `[[calendar]]` fields for all calendar values `calendar`. The value of this field must be a list of records, each of which has a subset of the fields shown in Table 4, where each field must have one of the values specified for the field in Table 4. Multiple records in a list may use the same subset of the fields as long as they have different values for the fields. The following subsets must be available for each locale:
  - weekday, year, month, day, hour, minute, second, fractionalSecondDigits
  - weekday, year, month, day, hour, minute, second
  - weekday, year, month, day
  - year, month, day
  - year, month
  - month, day
  - hour, minute, second, fractionalSecondDigits
  - hour, minute, second
  - hour, minute
  - dayPeriod, hour
  - dayPeriod, hour, minute, second
  - dayPeriod, hour, minute

Each of the records must also have the following fields:

1. A `[[pattern]]` field, whose value is a String value that contains for each of the date and time format component fields of the record a substring starting with "{", followed by the name of the field, followed by "}".
2. If the record has an `[[hour]]` field, it must also have a `[[pattern12]]` field, whose value is a String value that, in addition to the substrings of the `[[pattern]]` field, contains at least one of the substrings "{ampm}" or "{dayPeriod}".
3. If the record has a `[[year]]` field, the `[[pattern]]` and `[[pattern12]]` values may contain the substrings "{yearName}" and "{relatedYear}".
4. A `[[rangePatterns]]` field with a `Record` value:
   - The `[[rangePatterns]]` record may have any of the fields in Table 6, where each field represents a range pattern and its value is a `Record`.
     - The name of the field indicates the largest calendar element that must be different between the start and end dates in order to use this range pattern. For example, if the field name is `[[Month]]`, it contains the range pattern that should be used to format a date range where the era and year values are the same, but the month value is different.
     - The record will contain the following fields:
       - A subset of the fields shown in the Property column of Table 4, where each field must have one of the values specified for that field in the Values column of Table 4. All fields required to format a date for any of the `[[PatternParts]]` records must be present.
A `[[PatternParts]]` field whose value is a list of Records each representing a part of the range pattern. Each record contains a `[[Pattern]]` field and a `[[Source]]` field. The `[[Pattern]]` field’s value is a String of the same format as the regular date pattern String. The `[[Source]]` field is one of the String values "shared", "startRange", or "endRange". It indicates which of the range’s dates should be formatted using the value of the `[[Pattern]]` field.

The `[[rangePatterns]]` record must have a `[[Default]]` field which contains the default range pattern used when the specific range pattern is not available. Its value is a list of records with the same structure as the other fields in the `[[rangePatterns]]` record.

5. If the record has an `[[hour]]` field, it must also have a `[[rangePatterns12]]` field. Its value is similar to the `Record` in `[[rangePatterns]]`, but it uses a String similar to `[[pattern12]]` for each part of the range pattern.

6. If the record has a `[[year]]` field, the `[[rangePatterns]]` and `[[rangePatterns12]]` fields may contain range patterns where the `[[Pattern]]` values may contain the substrings "{yearName}" and "{relatedYear}".

`[[LocaleData]]` must have a `[[styles]]` field. The `[[styles]]` field must be a `Record` with `[[calendar]]` fields for all calendar values `calendar`. The calendar records must contain `[[DateFormat]]`, `[[TimeFormat]]`, `[[DateTimeFormat]]` and `[[DateTimeRangeFormat]]` fields, the value of these fields are Records, where each of which has `[[full]]`, `[[long]]`, `[[medium]]` and `[[short]]` fields. For `[[DateTimeFormat]]` and `[[TimeFormat]]`, the value of these fields must be a record, which has a subset of the fields shown in Table 4, where each field must have one of the values specified for the field in Table 4. Each of the records must also have the following fields:

1. A `[[pattern]]` field, whose value is a String value that contains for each of the date and time format component fields of the record a substring starting with "{", followed by the name of the field, followed by "}".

2. If the record has an `[[hour]]` field, it must also have a `[[pattern12]]` field, whose value is a String value that, in addition to the substrings of the pattern field, contains at least one of the substrings "{ampm}" or "{dayPeriod}".

3. A `[[rangePatterns]]` field that contains a record similar to the one described in the `[[formats]]` field.

4. If the record has an `[[hour]]` field, it must also have a `[[rangePatterns12]]` field. Its value is similar to the record in `[[rangePatterns]]` but it uses a string similar to `[[pattern12]]` for each range pattern.

For `[[DateTimeFormat]]`, the field value must be a string pattern which contains the strings "{0}" and "{1}". For `[[DateTimeRangeFormat]]` the value of these fields must be a nested record which also has `[[full]]`, `[[long]]`, `[[medium]]` and `[[short]]` fields. The `[[full]]`, `[[long]]`, `[[medium]]` and `[[short]]` fields in the enclosing record refer to the date style of the range pattern, while the fields in the nested record refers to the time style of the range pattern. The value of these fields in the nested record is a record with a `[[rangePatterns]]` field and a `[[rangePatterns12]]` field which are similar to the `[[rangePatterns]]` and `[[rangePatterns12]]` fields in `[[DateTimeFormat]]` and `[[TimeFormat]]`.

NOTE 2 For example, an implementation might include the following record as part of its English locale data:

- `[[hour]]: "numeric"
- `[[minute]]: "numeric"
- `[[pattern]]: "{hour}:{minute}"`
- `[[pattern12]]: "{hour}:{minute} {ampm}"`
- `[[rangePatterns]]:
  - `[[Hour]]:
    - `[[hour]]: "numeric"
    - `[[minute]]: "numeric"`
- [[PatternParts]]:
  - [[[Source]]: "startRange", [[[Pattern]]: "(hour):
    (minute)"
  - [[[Source]]: "shared", [[[Pattern]]: " - "
  - [[[Source]]: "endRange", [[[Pattern]]: "(hour):
    (minute)"
- [[Minute]]:
  - [hour]: "numeric"
  - [minute]: "numeric"
  - [[PatternParts]]:
    - [[[Source]]: "startRange", [[[Pattern]]: "(hour):
      (minute)"
    - [[[Source]]: "shared", [[[Pattern]]: " - "
    - [[[Source]]: "endRange", [[[Pattern]]: "(hour):
      (minute)"
- [[Default]]:
  - [year]: "2-digit"
  - [month]: "numeric"
  - [day]: "numeric"
  - [hour]: "numeric"
  - [minute]: "numeric"
  - [[PatternParts]]:
    - [[[Source]]: "startRange", [[[Pattern]]: "
      (day)/(month)/(year), (hour):(minute)"
    - [[[Source]]: "shared", [[[Pattern]]: " - "
    - [[[Source]]: "endRange", [[[Pattern]]: "
      (day)/(month)/(year), (hour):(minute)"
- [[rangePatterns12]]:
  - [[Hour]]:
    - [hour]: "numeric"
    - [minute]: "numeric"
    - [[PatternParts]]:
      - [[[Source]]: "startRange", [[[Pattern]]: "(hour):
        (minute)"
      - [[[Source]]: "shared", [[[Pattern]]: " - "
      - [[[Source]]: "endRange", [[[Pattern]]: "(hour):
        (minute)"
      - [[[Source]]: "shared", [[[Pattern]]: " (ampm)"
  - [[Minute]]:
    - [hour]: "numeric"
    - [minute]: "numeric"
    - [[PatternParts]]:
      - [[[Source]]: "startRange", [[[Pattern]]: "(hour):
        (minute)"
      - [[[Source]]: "shared", [[[Pattern]]: " - "
      - [[[Source]]: "endRange", [[[Pattern]]: "(hour):
        (minute)"
      - [[[Source]]: "shared", [[[Pattern]]: " (ampm)"
  - [[Default]]:
    - [year]: "2-digit"
    - [month]: "numeric"
    - [day]: "numeric"
    - [hour]: "numeric"
    - [minute]: "numeric"
    - [[PatternParts]]:
NOTE 3 It is recommended that implementations use the locale data provided by the Common Locale Data Repository (available at http://cldr.unicode.org).

11.4 Properties of the Intl.DateTimeFormat Prototype Object

The Intl.DateTimeFormat prototype object is itself an ordinary object. %DateTimeFormat.prototype% is not an Intl.DateTimeFormat instance and does not have an [[InitializedDateTimeFormat]] internal slot or any of the other internal slots of Intl.DateTimeFormat instance objects.

11.4.1 Intl.DateTimeFormat.prototype.constructor

The initial value of Intl.DateTimeFormat.prototype.constructor is the intrinsic object %DateTimeFormat%.

11.4.2 Intl.DateTimeFormat.prototype [ @@toStringTag ]

The initial value of the @@toStringTag property is the String value "Intl.DateTimeFormat". This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

11.4.3 get Intl.DateTimeFormat.prototype.format

Intl.DateTimeFormat.prototype.format is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let dtf be the this value.
2. If `Type(dtf)` is not Object, throw a `TypeError` exception.
3. Let `dtf` be `UnwrapDateTimeFormat(dtf)`.
4. If `dtf.[[BoundFormat]]` is `undefined`, then
   a. Let `F` be a new built-in function object as defined in DateTime Format Functions (11.1.6).
   b. Set `F.[[DateTimeFormat]]` to `dtf`.
   c. Set `dtf.[[BoundFormat]]` to `F`.
5. Return `dtf.[[BoundFormat]]`.

**NOTE**

The returned function is bound to `dtf` so that it can be passed directly to `Array.prototype.map` or other functions. This is considered a historical artefact, as part of a convention which is no longer followed for new features, but is preserved to maintain compatibility with existing programs.

### 11.4.4 Intl.DateTimeFormat.prototype.formatToParts (date)

When the `formatToParts` method is called with an argument `date`, the following steps are taken:

1. Let `dtf` be the `this` value.
2. Perform `%RequireInternalSlot(dtf, [[InitializedDateTimeFormat]])`.
3. If `date` is `undefined`, then
   a. Let `x` be `Call(%Date.now%, undefined)`.
4. Else,
   a. Let `x` be `ToNumber(date)`.
5. Return `FormatDateTimeToParts(dtf, x)`.

### 11.4.5 Intl.DateTimeFormat.prototype.formatRange (startDate, endDate)

When the `formatRange` method is called with arguments `startDate` and `endDate`, the following steps are taken:

1. Let `dtf` be this value.
2. Perform `%RequireInternalSlot(dtf, [[InitializedDateTimeFormat]])`.
3. If `startDate` is `undefined` or `endDate` is `undefined`, throw a `TypeError` exception.
4. Let `x` be `ToNumber(startDate)`.
5. Let `y` be `ToNumber(endDate)`.
6. Return `FormatDateTimeRangeToParts(dtf, x, y)`.

### 11.4.6 Intl.DateTimeFormat.prototype.formatRangeToParts (startDate, endDate)

When the `formatRangeToParts` method is called with arguments `startDate` and `endDate`, the following steps are taken:

1. Let `dtf` be `this` value.
2. Perform `%RequireInternalSlot(dtf, [[InitializedDateTimeFormat]])`.
3. If `startDate` is `undefined` or `endDate` is `undefined`, throw a `TypeError` exception.
4. Let `x` be `ToNumber(startDate)`.
5. Let `y` be `ToNumber(endDate)`.
6. Return `FormatDateTimeRangeToParts(dtf, x, y)`.

### 11.4.7 Intl.DateTimeFormat.prototype.resolvedOptions ()

This function provides access to the locale and formatting options computed during initialization of the object.
1. Let `dtf` be the `this` value.
2. If `Type(dtf)` is not `Object`, throw a `TypeError` exception.
3. Let `dtf` be ? `UnwrapDateTimeFormat(dtf)`.
4. Let `options` be `! OrdinaryObjectCreate(%Object.prototype%)`.
5. For each row of Table 7, except the header row, in table order, do
   a. Let `p` be the Property value of the current row.
   b. If `p` is "hour12", then
      i. Let `hc` be `dtf.[[HourCycle]]`.
      ii. If `hc` is "h11" or "h12", let `v` be `true`.
      iii. Else if, `hc` is "h23" or "h24", let `v` be `false`.
      iv. Else, let `v` be `undefined`.
   c. Else,
      i. Let `v` be the value of `dtf`'s internal slot whose name is the Internal Slot value of the current row.
   d. If the Internal Slot value of the current row is an Internal Slot value in Table 4, then
      i. If `dtf.[[DateStyle]]` is not `undefined` or `dtf.[[TimeStyle]]` is not `undefined`, then
         1. Let `v` be `undefined`.
      e. If `v` is not `undefined`, then
         i. Perform `! CreateDataPropertyOrThrow(options, p, v)`.
6. Return `options`.

</tbody>
</table>
For web compatibility reasons, if the property "hourCycle" is set, the "hour12" property should be set to true when "hourCycle" is "h11" or "h12", or to false when "hourCycle" is "h23" or "h24".

NOTE 1 In this version of the ECMAScript 2021 Internationalization API, the "timeZone" property will be the name of the default time zone if no "timeZone" property was provided in the options object provided to the Intl.DateTimeFormat constructor. The first edition left the "timeZone" property undefined in this case.

NOTE 2 For compatibility with versions prior to the fifth edition, the "hour12" property is set in addition to the "hourCycle" property.

11.5 Properties of Intl.DateTimeFormat Instances

Intl.DateTimeFormat instances are ordinary objects that inherit properties from %DateTimeFormat.prototype%.

Intl.DateTimeFormat instances have an [[InitializedDateTimeFormat]] internal slot.

Intl.DateTimeFormat instances also have several internal slots that are computed by the constructor:

- [[Locale]] is a String value with the language tag of the locale whose localization is used for formatting.
- [[Calendar]] is a String value with the "type" given in Unicode Technical Standard 35 for the calendar used for formatting.
- [[NumberingSystem]] is a String value with the "type" given in Unicode Technical Standard 35 for the numbering system used for formatting.
- [[TimeZone]] is a String value with the IANA time zone name of the time zone used for formatting.
- [[Weekday]], [[Era]], [[Year]], [[Month]], [[Day]], [[DayPeriod]], [[Hour]], [[Minute]], [[Second]], [[TimeZoneName]] are each either undefined, indicating that the component is not used for formatting, or one of the String values given in Table 4, indicating how the component should be presented in the formatted output.
- [[FractionalSecondDigits]] is either undefined or a positive, non-zero integer Number value indicating the fraction digits to be used for fractional seconds. Numbers will be rounded or padded with trailing zeroes if necessary.
- [[HourCycle]] is a String value indicating whether the 12-hour format ("h11", "h12") or the 24-hour format ("h23", "h24") should be used. "h11" and "h23" start with hour 0 and go up to 11 and 23 respectively. "h12" and "h24" start with hour 1 and go up to 12 and 24. [[HourCycle]] is only used when [[Hour]] is not undefined.
- [[DateTimeStyle]], [[TimeStyle]] are each either undefined, or a String value with values "full", "long", "medium", or "short".
- [[Pattern]] is a String value as described in 11.3.3.
- [[RangePatterns]] is a Record as described in 11.3.3.

Finally, Intl.DateTimeFormat instances have a [[BoundFormat]] internal slot that caches the function returned by the format accessor (11.4.3).

12 DisplayNames Objects

12.1 Abstract Operations for DisplayNames Objects
12.1.1 CanonicalCodeForDisplayNames (type, code)

The CanonicalCodeForDisplayNames abstract operation is called with arguments type and code. It verifies that the code argument represents a well-formed code according to the type argument and returns the case-regularized form of the code. The algorithm refers to UTS 35's Unicode Language and Locale Identifiers grammar. The following steps are taken:

1. If type is "language", then
   a. If code does not match the unicode_language_id production, throw a RangeError exception.
   b. If IsStructurallyValidLanguageTag(code) is false, throw a RangeError exception.
   c. Set code to CanonicalizeUnicodeLocaleId(code).
   d. Return code.
2. If type is "region", then
   a. If code does not match the unicode_region_subtag production, throw a RangeError exception.
   b. Let code be the result of mapping code to upper case as described in 6.1.
   c. Return code.
3. If type is "script", then
   a. If code does not match the unicode_script_subtag production, throw a RangeError exception.
   b. Let code be the result of mapping the first character in code to upper case, and mapping the second, third, and fourth character in code to lower case, as described in 6.1.
   c. Return code.
4. Assert: type is "currency".
5. If ! IsWellFormedCurrencyCode(code) is false, throw a RangeError exception.
6. Let code be the result of mapping code to upper case as described in 6.1.
7. Return code.

12.2 The Intl.DisplayNames Constructor

The DisplayNames constructor is the %DisplayNames% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

12.2.1 Intl.DisplayNames (locales, options)

When the Intl.DisplayNames function is called with arguments locales and options, the following steps are taken:

1. If NewTarget is undefined, throw a TypeError exception.
2. Let displayNames be ? OrdinaryCreateFromConstructor(NewTarget, "%DisplayNames.prototype%", « [[InitializedDisplayNames]], [[Locale]], [[Style]], [[Type]], [[Fallback]], [[Fields]] »).
4. If options is undefined, throw a TypeError exception.
5. Let options be ? GetOptionsObject(options).
6. Let opt be a new Record.
7. Let localeData be %DisplayNames%.[[LocaleData]].
9. Set opt.[[localeMatcher]] to matcher.
10. Let r be ResolveLocale(%DisplayNames%.[[AvailableLocales]], requestedLocales, opt, %DisplayNames%.[[RelevantExtensionKeys]]).
12. Set displayNames.[[Style]] to style.
14. If `type` is `undefined`, throw a `TypeError` exception.
15. Set `displayName[[Type]]` to `type`.
17. Set `displayName[[Fallback]]` to `fallback`.
18. Set `displayName[[Locale]]` to the value of `r.[[Locale]]`.
19. Let `dataLocale` be `r.[[dataLocale]]`.
20. Let `dataLocaleData` be `localeData.[[-dataLocale]]`.
21. Let `types` be `dataLocaleData.[[types]]`.
22. Assert: `types` is a Record (see 12.3.3).
23. Let `typeFields` be `types.[[<type>]]`.
24. Assert: `typeFields` is a Record (see 12.3.3).
25. Let `styleFields` be `typeFields.[[<style>]]`.
26. Assert: `styleFields` is a Record (see 12.3.3).
27. Set `displayName[[Fields]]` to `styleFields`.
28. Return `displayName`.

12.3 Properties of the Intl.DisplayNames Constructor

The Intl.DisplayNames constructor has the following properties:

12.3.1 Intl.DisplayNames.prototype

The value of `Intl.DisplayNames.prototype` is `%DisplayNames.prototype%`.

This property has the attributes `[[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false`.

12.3.2 Intl.DisplayNames.supportedLocalesOf ( locales [ , options ] )

When the `supportedLocalesOf` method of `%DisplayNames%` is called, the following steps are taken:

1. Let `availableLocales` be `%DisplayNames%.[[AvailableLocales]]`.
2. Let `requestedLocales` be ? `CanonicalizeLocaleList(locales)`.

12.3.3 Internal slots

The value of the `[[AvailableLocales]]` internal slot is implementation-defined within the constraints described in 9.1.

The value of the `[[RelevantExtensionKeys]]` internal slot is « ».

The value of the `[[LocaleData]]` internal slot is implementation-defined within the constraints described in 9.1 and the following additional constraints:

- `[[LocaleData]][[<locale>]]` must have a `[[types]]` field for all locale values `locale`. The value of this field must be a Record, which must have fields with the names of all display name types: "language", "region", "script", and "currency".
- The value of the fields "language", "region", "script", and "currency" must be Records, which must have fields with the names of all display name styles: "narrow", "short", and "long".
- The display name style fields under display name type "language" should contain Records with keys corresponding to language codes matching the `unicode_language_id` production. The value of these fields must be string values.
• The display name style fields under display name type "region" should contain Records with keys corresponding to region codes. The value of these fields must be string values.
• The display name style fields under display name type "script" should contain Records with keys corresponding to script codes. The value of these fields must be string values.
• The display name style fields under display name type "currency" should contain Records with keys corresponding to currency codes. The value of these fields must be string values.

NOTE It is recommended that implementations use the locale data provided by the Common Locale Data Repository (available at http://cldr.unicode.org/).

12.4 Properties of the Intl.DisplayNames Prototype Object

The Intl.DisplayNames prototype object is itself an ordinary object. %DisplayNames.prototype% is not an Intl.DisplayNames instance and does not have an [[InitializedDisplayNames]] internal slot or any of the other internal slots of Intl.DisplayNames instance objects.

12.4.1 Intl.DisplayNames.prototype.constructor

The initial value of Intl.DisplayNames.prototype.constructor is the intrinsic object %DisplayNames%.

12.4.2 Intl.DisplayNames.prototype[ @@toStringTag ]

The initial value of the @@toStringTag property is the String value "Intl.DisplayNames".
This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

12.4.3 Intl.DisplayNames.prototype.of ( code )

When the Intl.DisplayNames.prototype.of is called with an argument code, the following steps are taken:

1. Let displayNames be this value.
2. Perform ? RequireInternalSlot(displayNames, [[InitializedDisplayNames]]).
3. Let code be ? ToString(code).
4. Let code be ? CanonicalCodeForDisplayNames(displayNames.[[Type]], code).
5. Let fields be displayNames.[[Fields]].
6. If fields has a field [[<code>]], return fields.[[<code>]].
7. If displayNames.[[Fallback]] is "code", return code.
8. Return undefined.

12.4.4 Intl.DisplayNames.prototype.resolvedOptions ()

This function provides access to the locale and options computed during initialization of the object.

1. Let displayNames be this value.
2. Perform ? RequireInternalSlot(displayNames, [[InitializedDisplayNames]]).
3. Let options be ! OrdinaryObjectCreate(%ObjectPrototype%).
4. For each row of Table 8, except the header row, in table order, do
   a. Let p be the Property value of the current row.
   b. Let v be the value of displayNames's internal slot whose name is the Internal Slot value of the current row.
   c. Assert: v is not undefined.
d. Perform \( \text{CreateDataPropertyOrThrow}(\text{options}, p, v) \).

5. Return \( \text{options} \).

<table>

</tbody>
</table>

### 12.5 Properties of Intl.DisplayNames Instances

Intl.DisplayNames instances are ordinary objects that inherit properties from %DisplayNames.prototype%.

Intl.DisplayNames instances have an [[InitializedDisplayNames]] internal slot.

Intl.DisplayNames instances also have several internal slots that are computed by the constructor:

- [[Locale]] is a String value with the language tag of the locale whose localization is used for formatting.
- [[Style]] is one of the String values "narrow", "short", or "long", identifying the display name style used.
- [[Type]] is one of the String values "language", "region", "script", or "currency", identifying the type of the display names requested.
- [[Fallback]] is one of the String values "code" or "none", identifying the fallback return when the system does not have the requested display name.
- [[Fields]] is a Record (see 12.3.3) which must have fields with keys corresponding to codes according to [[Style]] and [[Type]].

### 13 ListFormat Objects

#### 13.1 Abstract Operations for ListFormat Objects

**13.1.1 DeconstructPattern (pattern, placeables)**

The DeconstructPattern abstract operation is called with arguments \( \text{pattern} \) (which must be a String) and \( \text{placeables} \) (which must be a Record), and deconstructs the pattern string into a list of parts.

The placeables record is a record whose keys are placeables tokens used in the pattern string, and values are parts records which will be used in the result List to represent the token part. Example:

```javascript
Input:
DeconstructPattern("AA{xx}BB{yy}CC", {
  {[xx]}: {[Type]: "hour", [Value]: "15"},
  {[yy]}: {[Type]: "minute", [Value]: "06"}}
)

Output (List of parts records):
*  
  {[Type]: "literal", [Value]: "AA"},
  {[Type]: "hour", [Value]: "15"},
```

© Ecma International 55
1. Let \( \text{patternParts} \) be \( \text{PartitionPattern}(\text{pattern}) \).
2. Let \( \text{result} \) be a new empty \( \text{List} \).
3. For each \( \text{Record} \{ [[\text{Type}]], [[\text{Value}]] \} \) \( \text{patternPart} \) of \( \text{patternParts} \), do
   a. Let \( \text{part} \) be \( \text{patternPart}[[\text{Type}]] \).
   b. If \( \text{part} \) is "literal", then
      i. Append \( \text{Record} \{ [[\text{Type}]]: "literal", [[\text{Value}]]: \text{patternPart}[[\text{Value}]] \} \) to \( \text{result} \).
   c. Else,
      i. Assert: \( \text{placeables} \) has a field \( [[<\text{part}>]] \).
      ii. Let \( \text{subst} \) be \( \text{placeables}[[<\text{part}>]] \).
      iii. If \( \text{Type}(\text{subst}) \) is List, then
          1. For each element \( s \) of \( \text{subst} \), do
              a. Append \( s \) to \( \text{result} \).
          iv. Else,
              1. Append \( \text{subst} \) to \( \text{result} \).
4. Return \( \text{result} \).

13.1.2 \text{CreatePartsFromList (} \text{listFormat, list} \) \text{)}

The \text{CreatePartsFromList} abstract operation is called with arguments \( \text{listFormat} \) (which must be an object initialized as a ListFormat) and \( \text{list} \) (which must be a \( \text{List} \) of String values), and creates the corresponding list of parts according to the effective locale and the formatting options of \( \text{listFormat} \). Each part is a \( \text{Record} \) with two fields: [[Type]], which must be a string with values "element" or "literal", and [[Value]] which must be a string or a number. The following steps are taken:

1. Let \( \text{size} \) be the number of elements of \( \text{list} \).
2. If \( \text{size} \) is 0, then
   a. Return a new empty \( \text{List} \).
3. If \( \text{size} \) is 2, then
   a. Let \( n \) be an index into \( \text{listFormat}[[\text{Templates}]] \) based on \( \text{listFormat}[[\text{Locale}]], \text{list}[0] \), and \( \text{list}[1] \).
   b. Let \( \text{pattern} \) be \( \text{listFormat}[[\text{Templates}}][[n]].[[\text{Pair}]] \).
   c. Let \( \text{first} \) be a new \( \text{Record} \{ [[\text{Type}]]: "element", [[\text{Value}]]: \text{list}[0] \} \).
   d. Let \( \text{second} \) be a new \( \text{Record} \{ [[\text{Type}]]: "element", [[\text{Value}]]: \text{list}[1] \} \).
   e. Let \( \text{placeables} \) be a new \( \text{Record} \{ [0]: \text{first}, [1]: \text{second} \} \).
   f. Return \( \text{DeconstructPattern}(\text{pattern}, \text{placeables}) \).
4. Let \( \text{last} \) be a new \( \text{Record} \{ [[\text{Type}]]: "element", [[\text{Value}]]: \text{list}[\text{size}-1] \} \).
5. Let \( \text{parts} \) be « \( \text{last} \) ».
6. Let \( i \) be \( \text{size} - 2 \).
7. Repeat, while \( i \geq 0 \),
   a. Let \( \text{head} \) be a new \( \text{Record} \{ [[\text{Type}]]: "element", [[\text{Value}]]: \text{list}[i] \} \).
   b. Let \( n \) be an implementation-defined index into \( \text{listFormat}[[\text{Templates}]] \) based on \( \text{listFormat}[[\text{Locale}]], \text{head} \), and \( \text{parts} \).
   c. If \( i \) is 0, then
      i. Let \( \text{pattern} \) be \( \text{listFormat}[[\text{Templates}}][[n]].[[\text{Start}]] \).
   d. Else if \( i \) is less than \( \text{size} - 2 \), then
      i. Let \( \text{pattern} \) be \( \text{listFormat}[[\text{Templates}}][[n]].[[\text{Middle}]] \).
   e. Else,
      i. Let \( \text{pattern} \) be \( \text{listFormat}[[\text{Templates}}][[n]].[[\text{End}]] \).
   f. Let \( \text{placeables} \) be a new \( \text{Record} \{ [0]: \text{head}, [1]: \text{parts} \} \).
   g. Set \( \text{parts} \) to \( \text{DeconstructPattern}(\text{pattern}, \text{placeables}) \).
8. Return \textit{parts}.

\section*{NOTE}
The index $n$ to select across multiple templates permits the conjunction to be
dependent on the context, as in Spanish, where either “y” or “e” may be selected,
depending on the following word.

\subsection*{13.1.3 \textit{FormatList}(\textit{listFormat}, \textit{list})}
The \textit{FormatList} abstract operation is called with arguments \textit{listFormat} (which must be an object
initialized as a ListFormat) and \textit{list} (which must be a \textit{List} of String values), and performs the following
steps:

1. Let \textit{parts} be \textit{CreatePartsFromList}(\textit{listFormat}, \textit{list}).
2. Let \textit{result} be an empty String.
3. For each Record \{[[Type]], [[Value]]\} \textit{part} in \textit{parts}, do
   a. Set \textit{result} to the \textit{string-concatenation} of \textit{result} and \textit{part.}[Value].
4. Return \textit{result}.

\subsection*{13.1.4 \textit{FormatListToParts}(\textit{listFormat}, \textit{list})}
The \textit{FormatListToParts} abstract operation is called with arguments \textit{listFormat} (which must be an object
initialized as a ListFormat) and \textit{list} (which must be a \textit{List} of String values), and performs the following
steps:

1. Let \textit{parts} be \textit{CreatePartsFromList}(\textit{listFormat}, \textit{list}).
2. Let \textit{result} be \textit{ArrayCreate}(0).
3. Let \textit{n} be 0.
4. For each Record \{[[Type]], [[Value]]\} \textit{part} in \textit{parts}, do
   a. Let \textit{O} be \textit{OrdinaryObjectCreate}(%Object.prototype%).
   b. Perform \textbf{CreateDataPropertyOrThrow}(\textit{O}, “type”, \textit{part.}[Type]).
   c. Perform \textbf{CreateDataPropertyOrThrow}(\textit{O}, “value”, \textit{part.}[Value]).
   d. Perform \textbf{CreateDataPropertyOrThrow}(\textit{result}, !\textit{ToString}(\textit{n}), \textit{O}).
   e. Increment \textit{n} by 1.
5. Return \textit{result}.

\subsection*{13.1.5 \textit{StringListFromIterable}(\textit{iterable})}
The abstract operation \textit{StringListFromIterable} performs the following steps:

1. If \textit{iterable} is \textbf{undefined}, then
   a. Return a new empty \textit{List}.
2. Let \textit{iteratorRecord} be ? \textbf{GetIterator}(\textit{iterable}).
3. Let \textit{list} be a new empty \textit{List}.
4. Let \textit{next} be \textbf{true}.
5. Repeat, while \textit{next} is not \textbf{false},
   a. Set \textit{next} to ? \textbf{IteratorStep}(\textit{iteratorRecord}).
   b. If \textit{next} is not \textbf{false}, then
      i. Let \textit{nextValue} be ? \textbf{IteratorValue}(\textit{next}).
      ii. If Type(\textit{nextValue}) is not String, then
         1. Let \textit{error} be \textbf{ThrowCompletion}(a newly created \textbf{TypeError} object).
         2. Return ? \textbf{IteratorClose}(\textit{iteratorRecord}, \textit{error}).
      iii. Append \textit{nextValue} to the end of the \textit{List} \textit{list}.
6. Return \textit{list}. 

© Ecma International
NOTE

This algorithm raises exceptions when it encounters values that are not Strings, because there is no obvious locale-aware coercion for arbitrary values.

13.2 The Intl.ListFormat Constructor

The ListFormat constructor is the %ListFormat% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

13.2.1 Intl.ListFormat ([ locales [, options ] ])

When the Intl.ListFormat function is called with optional arguments locales and options, the following steps are taken:

1. If NewTarget is undefined, throw a TypeError exception.
2. Let listFormat be ? OrdinaryCreateFromConstructor(NewTarget, "%ListFormat.prototype%", « [[InitializedListFormat]], [[Locale]], [[Type]], [[Style]], [[Templates]] »).
4. Let options be ? GetOptionsObject(options).
5. Let opt be a new Record.
7. Set opt.[[localeMatcher]] to matcher.
8. Let localeData be %ListFormat%.[[LocaleData]].
9. Let r be ResolveLocale(%ListFormat%.[[AvailableLocales]], requestedLocales, opt, %ListFormat%.[[RelevantExtensionKeys]], localeData).
10. Set listFormat.[[Locale]] to r.[[locale]].
11. Let type be ? GetOption(options, "type", "string", "conjunction", "disjunction", "unit" », "conjunction").
12. Set listFormat.[[Type]] to type.
14. Set listFormat.[[Style]] to style.
15. Let dataLocale be r.[[dataLocale]].
16. Let dataLocaleData be localeData.[[<dataLocale>]].
17. Let dataLocaleTypes be dataLocaleData.[[<type>]].
18. Set listFormat.[[Templates]] to dataLocaleTypes.[[<style>]].
19. Return listFormat.

13.3 Properties of the Intl.ListFormat Constructor

The Intl.ListFormat constructor has the following properties:

13.3.1 Intl.ListFormat.prototype

The value of Intl.ListFormat.prototype is %ListFormat.prototype%.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

13.3.2 Intl.ListFormat.supportedLocalesOf ( locales [, options ] )

When the supportedLocalesOf method is called with arguments locales and options, the following steps are taken:

1. Let availableLocales be %ListFormat%.[[AvailableLocales]].
2. Let `requestedLocales` be `CanonicalizeLocaleList(locales)`.

### 13.3.3 Internal slots

The value of the `[[AvailableLocales]]` internal slot is implementation-defined within the constraints described in 9.1.

The value of the `[[RelevantExtensionKeys]]` internal slot is « ».

**NOTE 1** Intl.ListFormat does not have any relevant extension keys.

The value of the `[[LocaleData]]` internal slot is implementation-defined within the constraints described in 9.1 and the following additional constraints, for each locale value `locale` in `%ListFormat%`:

- `[[LocaleData]][[<locale>]]` is a `Record` which has three fields `[[conjunction]]`, `[[disjunction]]`, and `[[unit]]`. Each of these is a `Record` which must have fields with the names of three formatting styles: `[[long]]`, `[[short]]`, and `[[narrow]]`.
- Each of those fields is considered a `ListFormat template set`, which must be a `List` of `Records` with fields named: `[[Pair]]`, `[[Start]]`, `[[Middle]]`, and `[[End]]`. Each of those fields must be a template string as specified in LDML List Format Rules. Each template string must contain the substrings "{0}" and "{1}" exactly once. The substring "{0}" should occur before the substring " {1}".

**NOTE 2** It is recommended that implementations use the locale data provided by the Common Locale Data Repository (available at http://cldr.unicode.org/). In LDML’s `listPattern`, `conjunction` corresponds to "standard", `disjunction` corresponds to "or", and `unit` corresponds to "unit".

**NOTE 3** Among the list types, `conjunction` stands for "and"-based lists (e.g., "A, B, and C"), `disjunction` stands for "or"-based lists (e.g., "A, B, or C"), and `unit` stands for lists of values with units (e.g., "5 pounds, 12 ounces").

### 13.4 Properties of the Intl.ListFormat Prototype Object

The Intl.ListFormat prototype object is itself an ordinary object. `%ListFormat.prototype%` is not an Intl.ListFormat instance and does not have an `[[InitializedListFormat]]` internal slot or any of the other internal slots of Intl.ListFormat instance objects.

#### 13.4.1 Intl.ListFormat.prototype.constructor

The initial value of `Intl.ListFormat.prototype.constructor` is the intrinsic object `%ListFormat%`.

#### 13.4.2 Intl.ListFormat.prototype [ @@toStringTag ]

The initial value of the `@@toStringTag` property is the String value "Intl.ListFormat".

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

#### 13.4.3 Intl.ListFormat.prototype.format ( list )
When the `format` method is called with an argument `list`, the following steps are taken:

1. Let `lf` be the `this` value.
3. Let `stringList` be ? `StringListFromIterable(list)`.
4. Return `FormatList(lf, stringList)`.

13.4.4 `Intl.ListFormat.prototype.formatToParts (list)`

When the `formatToParts` method is called with an argument `list`, the following steps are taken:

1. Let `lf` be the `this` value.
3. Let `stringList` be ? `StringListFromIterable(list)`.
4. Return `FormatListToParts(lf, stringList)`.

13.4.5 `Intl.ListFormat.prototype.resolvedOptions ()`

This function provides access to the locale and options computed during initialization of the object.

1. Let `lf` be the `this` value.
3. Let `options` be ! `OrdinaryObjectCreate(%Object.prototype%)`.
4. For each row of Table 9, except the header row, in table order, do
   a. Let `p` be the Property value of the current row.
   b. Let `v` be the value of `lf`'s internal slot whose name is the Internal Slot value of the current row.
   c. Assert: `v` is not `undefined`.
   d. Perform ! `CreateDataPropertyOrThrow(options, p, v)`.
5. Return `options`.

<table>
<thead>
<tr>
<th>Internal Slot</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Locale]]</td>
<td>&quot;locale&quot;</td>
</tr>
<tr>
<td>[[Type]]</td>
<td>&quot;type&quot;</td>
</tr>
<tr>
<td>[[Style]]</td>
<td>&quot;style&quot;</td>
</tr>
</tbody>
</table>

13.5 Properties of Intl.ListFormat Instances

Intl.ListFormat instances inherit properties from `%ListFormat.prototype%`.

Intl.ListFormat instances have an [[InitializedListFormat]] internal slot.

Intl.ListFormat instances also have several internal slots that are computed by the constructor:

- [[Locale]] is a String value with the language tag of the locale whose localization is used by the list format styles.
- [[Type]] is one of the String values "conjunction", "disjunction", or "unit", identifying the list of types used.
- [[Style]] is one of the String values "long", "short", or "narrow", identifying the list formatting style used.
- [[Templates]] is a ListFormat template set.
14 Locale Objects

14.1 The Intl.Locale Constructor

The Locale constructor is the `%Locale%` intrinsic object and a standard built-in property of the Intl object.

14.1.1 ApplyOptionsToTag ( tag, options )

The following algorithm refers to UTS 35's Unicode Language and Locale Identifiers grammar.

1. Assert: Type(tag) is String.
2. Assert: Type(options) is Object.
3. If IsStructurallyValidLanguageTag(tag) is false, throw a RangeError exception.
5. If language is not undefined, then
   a. If language does not match the unicode_language_subtag production, throw a RangeError exception.
7. If script is not undefined, then
   a. If script does not match the unicode_script_subtag production, throw a RangeError exception.
9. If region is not undefined, then
   a. If region does not match the unicode_region_subtag production, throw a RangeError exception.
10. Set tag to CanonicalizeUnicodeLocaleId(tag).
11. Assert: tag matches the unicode_locale_id production.
12. Let languaged be the substring of tag corresponding to the unicode_language_id production.
13. If language is not undefined, then
    a. Set languaged to languaged with the substring corresponding to the unicode_language_subtag production replaced by the string language.
14. If script is not undefined, then
    a. If languaged does not contain a unicode_script_subtag production, then
       i. Set languaged to the string-concatenation of the unicode_language_subtag production of languaged, "+", script, and the rest of languaged.
    b. Else,
       i. Set languaged to languaged with the substring corresponding to the unicode_script_subtag production replaced by the string script.
15. If region is not undefined, then
    a. If languaged does not contain a unicode_region_subtag production, then
       i. Set languaged to the string-concatenation of the unicode_language_subtag production of languaged, the substring corresponding to "+" and the ‘unicode_script_subtag’ production if present, "+", region, and the rest of languaged.
    b. Else,
       i. Set languaged to languaged with the substring corresponding to the unicode_region_subtag production replaced by the string region.
16. Set tag to tag with the substring corresponding to the unicode_language_id production replaced by the string languaged.
17. Return CanonicalizeUnicodeLocaleId(tag).
The following algorithm refers to UTS 35’s Unicode Language and Locale Identifiers grammar.

1. Assert: Type(tag) is String.
2. Assert: tag matches the unicode.locale_id production.
3. If tag contains a substring that is a Unicode locale extension sequence, then
   a. Let extension be the String value consisting of the first substring of tag that is a Unicode locale extension sequence.
   b. Let components be ! UnicodeExtensionComponents(extension).
   c. Let attributes be components.\[
   \text{{Attributes}}\].
   d. Let keywords be components.\[
   \text{{Keywords}}\].
4. Else,
   a. Let attributes be a new empty List.
   b. Let keywords be a new empty List.
5. Let result be a new Record.
6. For each element key of relevantExtensionKeys, do
   a. Let value be undefined.
   b. If keywords contains an element whose [[Key]] is the same as key, then
      i. Let entry be the element of keywords whose [[Key]] is the same as key.
      ii. Let value be entry.\[
      \text{{Value}}\].
   c. Else,
      i. Let entry be empty.
   d. Assert: options has a field [[<key_>]].
   e. Let optionsValue be options.\[
   \text{{<key_>}}\].
   f. If optionsValue is not undefined, then
      i. Assert: Type(optionsValue) is String.
      ii. Let value be optionsValue.
      iii. If entry is not empty, then
         1. Set entry.\[
         \text{{Value}}\] to value.
      iv. Else,
         1. Append the Record \{ [[Key]: key, [[Value]: value ] to keywords.
   g. Set result.\[
   \text{{<key_>}}\] to value.
7. Let locale be the String value that is tag with all Unicode locale extension sequences removed.
8. Let newExtension be a Unicode BCP 47 U Extension based on attributes and keywords.
9. If newExtension is not the empty String, then
   a. Let locale be ! InsertUnicodeExtensionAndCanonicalize(locale, newExtension).
10. Set result.\text{[[locale]]} to locale.
11. Return result.

14.1.3 Intl.Locale ( tag [, options ] )

The following algorithm refers to UTS 35’s Unicode Language and Locale Identifiers grammar. When the Intl.Locale function is called with an argument tag and an optional argument options, the following steps are taken:

1. If NewTarget is undefined, throw a TypeError exception.
2. Let relevantExtensionKeys be %Locale%.\text{[[RelevantExtensionKeys]]}.
3. Let internalSlotsList be « \text{[[InitializedLocale]], [[Locale]], [[Calendar]], [[Collation]], [[HourCycle]], [[NumberingSystem]] »}.
4. If relevantExtensionKeys contains "kf", then
   a. Append \text{[[CaseFirst]]} as the last element of internalSlotsList.
5. If relevantExtensionKeys contains "kn", then
   a. Append \text{[[Numeric]]} as the last element of internalSlotsList.
6. Let `locale` be `OrdinaryCreateFromConstructor(NewTarget, "%Locale.prototype%", internalSlotsList).

7. If `Type(tag)` is not String or Object, throw a `TypeError` exception.

8. If `Type(tag)` is Object and `tag` has an `[[InitializedLocale]]` internal slot, then
   a. Let `tag` be `tag.[[Locale]].`

9. Else,
   a. Let `tag` be `ToString(tag)`.

10. Set `options` to `CoerceOptionsToObject(options)`.

11. Set `tag` to `ApplyOptionsToTag(tag, options)`.

12. Let `opt` be a new Record.

13. Let `calendar` be `GetOption(options, "calendar", "string", undefined, undefined)`.

14. If `calendar` is not `undefined`, then
   a. If `calendar` does not match the `type` sequence (from UTS 35 Unicode Locale Identifier, section 3.2), throw a `RangeError` exception.

15. Set `opt.[[ca]]` to `calendar`.

16. Let `collation` be `GetOption(options, "collation", "string", undefined, undefined)`.

17. If `collation` is not `undefined`, then
   a. If `collation` does not match the `type` sequence (from UTS 35 Unicode Locale Identifier, section 3.2), throw a `RangeError` exception.

18. Set `opt.[[co]]` to `collation`.

20. Set `opt.[[hc]]` to `hc`.

22. Set `opt.[[kf]]` to `kf`.

23. Let `kn` be `GetOption(options, "numeric", "boolean", undefined, undefined)`.

24. If `kn` is not `undefined`, set `kn` to `ToString(kn)`.

25. Set `opt.[[kn]]` to `kn`.

26. Let `numberingSystem` be `GetOption(options, "numberingSystem", "string", undefined, undefined)`.

27. If `numberingSystem` is not `undefined`, then
   a. If `numberingSystem` does not match the `type` sequence (from UTS 35 Unicode Locale Identifier, section 3.2), throw a `RangeError` exception.

28. Set `opt.[[nu]]` to `numberingSystem`.

29. Let `r` be `ApplyUnicodeExtensionToTag(tag, opt, relevantExtensionKeys)`.

30. Set `locale.[[Locale]]` to `r.[[locale]]`.

31. Set `locale.[[Calendar]]` to `r.[[ca]]`.

32. Set `locale.[[Collation]]` to `r.[[co]]`.

33. Set `locale.[[HourCycle]]` to `r.[[hc]]`.

34. If `relevantExtensionKeys` contains "kf", then
   a. Set `locale.[[CaseFirst]]` to `r.[[kf]]`.

35. If `relevantExtensionKeys` contains "kn", then
   a. If `SameValue(r.[[kn]], "true")` is `true` or `r.[[kn]]` is the empty String, then
      i. Set `locale.[[Numeric]]` to `true`.
   b. Else,
      i. Set `locale.[[Numeric]]` to `false`.

36. Set `locale.[[NumberingSystem]]` to `r.[[nu]]`.

37. Return `locale`.

### 14.2 Properties of the Intl.Locale Constructor

The Intl.Locale constructor has the following properties:

#### 14.2.1 Intl.Locale.prototype

© Ecma International
The value of `Intl.Locale.prototype` is `%Locale.prototype%.

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }`.

### 14.2.2 Internal slots

The value of the `[[ RelevantExtensionKeys ]]` internal slot is « "ca", "co", "he", "kf", "kn", "nu" ». If `%Collator%.[[ RelevantExtensionKeys ]]` does not contain "kf", then remove "kf" from `%Locale%.[[ RelevantExtensionKeys ]]`. If `%Collator%.[[ RelevantExtensionKeys ]]` does not contain "kn", then remove "kn" from `%Locale%.[[ RelevantExtensionKeys ]]`.

### 14.3 Properties of the Intl.Locale Prototype Object

The Intl.Locale prototype object is itself an ordinary object. `%Locale.prototype%` is not an Intl.Locale instance and does not have an `[[ InitializedLocale ]]` internal slot or any of the other internal slots of Intl.Locale instance objects.

#### 14.3.1 Intl.Locale.prototype.constructor

The initial value of `Intl.Locale.prototype.constructor` is `%Locale%`.

#### 14.3.2 Intl.Locale.prototype[ @@toStringTag ]

The initial value of the `@@toStringTag` property is the String value "Intl.Locale".

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }`.

#### 14.3.3 Intl.Locale.prototype.maximize ( )

1. Let `loc` be the `this` value.
2. Perform `? RequireInternalSlot(loc, [[ InitializedLocale ]]).`
3. Let `maximal` be the result of the `Add Likely Subtags` algorithm applied to `loc. [[Locale]]`. If an error is signaled, set `maximal` to `loc. [[Locale]]`.
4. Return `! Construct(%Locale%, maximal)`.

#### 14.3.4 Intl.Locale.prototype.minimize ( )

1. Let `loc` be the `this` value.
2. Perform `? RequireInternalSlot(loc, [[ InitializedLocale ]]).`
3. Let `minimal` be the result of the `Remove Likely Subtags` algorithm applied to `loc. [[Locale]]`. If an error is signaled, set `minimal` to `loc. [[Locale]]`.
4. Return `! Construct(%Locale%, minimal)`.

#### 14.3.5 Intl.Locale.prototype.toString ( )

1. Let `loc` be the `this` value.
2. Perform `? RequireInternalSlot(loc, [[ InitializedLocale ]]).`
3. Return `loc. [[Locale]]`.

#### 14.3.6 get Intl.Locale.prototype.baseName

`Intl.Locale.prototype.baseName` is an accessor property whose set accessor function is `undefined`. The following algorithm refers to UTS 35’s Unicode Language and Locale Identifiers.
Its get accessor function performs the following steps:

1. Let `loc` be the this value.
2. Perform `? RequireInternalSlot(loc, [[InitializedLocale]])`.
3. Let `locale` be `loc.[[Locale]]`.
4. Return the substring of `locale` corresponding to the `unicode_language_id` production.

14.3.7 `get Intl.Locale.prototype.calendar`

`Intl.Locale.prototype.calendar` is an accessor property whose set accessor function is `undefined`. Its get accessor function performs the following steps:

1. Let `loc` be the this value.
2. Perform `? RequireInternalSlot(loc, [[InitializedLocale]])`.
3. Return `loc.[[Calendar]]`.

14.3.8 `get Intl.Locale.prototype.caseFirst`

This property only exists if `%Locale%.[[RelevantExtensionKeys]]` contains "kf".

`Intl.Locale.prototype.caseFirst` is an accessor property whose set accessor function is `undefined`. Its get accessor function performs the following steps:

1. Let `loc` be the this value.
2. Perform `? RequireInternalSlot(loc, [[InitializedLocale]])`.
3. Return `loc.[[CaseFirst]]`.

14.3.9 `get Intl.Locale.prototype.collation`

`Intl.Locale.prototype.collation` is an accessor property whose set accessor function is `undefined`. Its get accessor function performs the following steps:

1. Let `loc` be the this value.
2. Perform `? RequireInternalSlot(loc, [[InitializedLocale]])`.
3. Return `loc.[[Collation]]`.

14.3.10 `get Intl.Locale.prototype.hourCycle`

`Intl.Locale.prototype.hourCycle` is an accessor property whose set accessor function is `undefined`. Its get accessor function performs the following steps:

1. Let `loc` be the this value.
2. Perform `? RequireInternalSlot(loc, [[InitializedLocale]])`.
3. Return `loc.[[HourCycle]]`.

14.3.11 `get Intl.Locale.prototype.numeric`

This property only exists if `%Locale%.[[RelevantExtensionKeys]]` contains "kn".

`Intl.Locale.prototype.numeric` is an accessor property whose set accessor function is `undefined`. Its get accessor function performs the following steps:

1. Let `loc` be the this value.
2. Perform `? RequireInternalSlot(loc, [[InitializedLocale]])`.
3. Return `loc.[[Numeric]]`.

© Ecma International
14.3.12  get Intl.Locale.prototype.numberingSystem

Intl.Locale.prototype.numberingSystem is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let loc be the this value.
2. Perform ? RequireInternalSlot(loc, [[InitializedLocale]]).
3. Return loc.[[NumberingSystem]].

14.3.13  get Intl.Locale.prototype.language

Intl.Locale.prototype.language is an accessor property whose set accessor function is undefined. The following algorithm refers to UTS 35’s Unicode Language and Locale Identifiers grammar. Its get accessor function performs the following steps:

1. Let loc be the this value.
2. Perform ? RequireInternalSlot(loc, [[InitializedLocale]]).
3. Let locale be loc.[[Locale]].
4. Assert: locale matches the unicode_locale_id production.
5. Return the substring of locale corresponding to the unicode_language_subtag production of the unicode_language_id.

14.3.14  get Intl.Locale.prototype.script

Intl.Locale.prototype.script is an accessor property whose set accessor function is undefined. The following algorithm refers to UTS 35’s Unicode Language and Locale Identifiers grammar. Its get accessor function performs the following steps:

1. Let loc be the this value.
2. Perform ? RequireInternalSlot(loc, [[InitializedLocale]]).
3. Let locale be loc.[[Locale]].
4. Assert: locale matches the unicode_locale_id production.
5. If the unicode_language_id production of locale does not contain the ["-" unicode_script_subtag] sequence, return undefined.
6. Return the substring of locale corresponding to the unicode_script_subtag production of the unicode_language_id.

14.3.15  get Intl.Locale.prototype.region

Intl.Locale.prototype.region is an accessor property whose set accessor function is undefined. The following algorithm refers to UTS 35’s Unicode Language and Locale Identifiers grammar. Its get accessor function performs the following steps:

1. Let loc be the this value.
2. Perform ? RequireInternalSlot(loc, [[InitializedLocale]]).
3. Let locale be loc.[[Locale]].
4. Assert: locale matches the unicode_locale_id production.
5. If the unicode_language_id production of locale does not contain the ["-" unicode_region_subtag] sequence, return undefined.
6. Return the substring of locale corresponding to the unicode_region_subtag production of the unicode_language_id.

15  NumberFormat Objects
15.1 Abstract Operations for NumberFormat Objects

15.1.1 SetNumberFormatDigitOptions ( intlObj, options, mnfdDefault, mxfdDefault, notation )

The abstract operation SetNumberFormatDigitOptions applies digit options used for number formatting onto the intl object.

1. Assert: Type(intlObj) is Object.
2. Assert: Type(options) is Object.
3. Assert: Type(mnfdDefault) is Number.
4. Assert: Type(mxfdDefault) is Number.
5. Let mnid be ? GetNumberOption(options, "minimumIntegerDigits", 1, 21, 1).
6. Let mnfd be ? Get(options, "minimumFractionDigits").
7. Let mxfd be ? Get(options, "maximumFractionDigits").
8. Let mnsd be ? Get(options, "minimumSignificantDigits").
9. Let mxsd be ? Get(options, "maximumSignificantDigits").
10. Set intlObj.[[MinimumIntegerDigits]] to mnid.
11. If mnsd is not undefined or mxsd is not undefined, then
   a. Set intlObj.[[RoundingType]] to significantDigits.
   b. Let mnsd be ? DefaultNumberOption(mnsd, 1, 21, 1).
   c. Let mxsd be ? DefaultNumberOption(mxsd, mnsd, 21, 21).
   d. Set intlObj.[[MinimumSignificantDigits]] to mnsd.
   e. Set intlObj.[[MaximumSignificantDigits]] to mxsd.
12. Else if mnfd is not undefined or mxfd is not undefined, then
   a. Set intlObj.[[RoundingType]] to fractionDigits.
   b. Let mnfd be ? DefaultNumberOption(mnfd, 0, 20, undefined).
   c. Let mxfd be ? DefaultNumberOption(mxfd, 0, 20, undefined).
   d. If mnfd is undefined, set mnfd to min(mnfdDefault, mxfd).
   e. Else if mxfd is undefined, set mxfd to max(mxfdDefault, mnfd).
   f. Else if mnfd is greater than mxfd, throw a RangeError exception.
   g. Set intlObj.[[MinimumFractionDigits]] to mnfd.
   h. Set intlObj.[[MaximumFractionDigits]] to mxfd.
13. Else if notation is "compact", then
   a. Set intlObj.[[RoundingType]] to compactRounding.
14. Else,
   a. Set intlObj.[[RoundingType]] to fractionDigits.
   b. Set intlObj.[[MinimumFractionDigits]] to mnfdDefault.
   c. Set intlObj.[[MaximumFractionDigits]] to mxfdDefault.

15.1.2 InitializeNumberFormat ( numberFormat, locales, options )

The abstract operation InitializeNumberFormat accepts the arguments numberFormat (which must be an object), locales, and options. It initializes numberFormat as a NumberFormat object. The following steps are taken:

The following algorithm refers to the type nonterminal from UTS 35's Unicode Locale Identifier grammar.

1. Let requestedLocales be ? CanonicalizeLocaleList(locales).
2. Set options to ? CoerceOptionsToObject(options).
3. Let opt be a new Record.
5. Set opt.[[localeMatcher]] to matcher.
6. Let \textit{numberingSystem} be ? \texttt{GetOption(options, "numberingSystem", "string", undefined, undefined)}.

7. If \textit{numberingSystem} is not undefined, then
   a. If \textit{numberingSystem} does not match the Unicode Locale Identifier type nonterminal, throw a RangeError exception.

8. Set \texttt{opt.[[nu]]} to \textit{numberingSystem}.

9. Let \texttt{localeData} be \%\texttt{NumberFormat%.[[LocaleData]]}.

10. Let \textit{r} be \texttt{ResolveLocale(\%NumberFormat%, [[AvailableLocales]], requestedLocales, \texttt{opt}, \%\texttt{NumberFormat%.[[RelevantExtensionKeys]]}, localeData)}.

11. Set \texttt{numberFormat.[[Locale]]} to \texttt{r.[[locale]]}.

12. Set \texttt{numberFormat.[[DataLocale]]} to \texttt{r.[[dataLocale]]}.

13. Set \texttt{numberFormat.[[NumberingSystem]]} to \texttt{r.[[nu]]}.

14. Perform ? \texttt{SetNumberFormatUnitOptions(numberFormat, options)}.

15. Set \texttt{style} be \texttt{numberFormat.[[Style]]}.

16. If \textit{style} is "currency", then
   a. Let \texttt{currency} be \texttt{numberFormat.[[Currency]]}.
   b. Let \texttt{cDigits} be \texttt{CurrencyDigits(currency)}.
   c. Let \texttt{mnfdDefault} be \texttt{cDigits}.
   d. Let \texttt{mxfdDefault} be \texttt{cDigits}.

17. Else,
   a. Let \texttt{mnfdDefault} be 0.
   b. If \textit{style} is "percent", then
      i. Let \texttt{mxfdDefault} be 0.
   c. Else,
      i. Let \texttt{mxfdDefault} be 3.

18. Let \textit{notation} be ? \texttt{GetOption(options, "notation", "string", ""standard", "scientific", "engineering", "compact" », "standard")}.

19. Set \texttt{numberFormat.[[Notation]]} to \texttt{notation}.

20. Perform ? \texttt{SetNumberFormatDigitOptions(numberFormat, options, mnfdDefault, mxfdDefault, notation)}.

21. Let \texttt{compactDisplay} be ? \texttt{GetOption(options, "compactDisplay", "string", ""short", "long" », "short")}.

22. If \textit{notation} is "compact", then
   a. Set \texttt{numberFormat.[[CompactDisplay]]} to \texttt{compactDisplay}.

23. Let \texttt{useGrouping} be ? \texttt{GetOption(options, "useGrouping", "boolean", undefined, true)}.

24. Set \texttt{numberFormat.[[UseGrouping]]} to \texttt{useGrouping}.

26. Set \texttt{numberFormat.[[SignDisplay]]} to \texttt{signDisplay}.

27. Return \texttt{numberFormat}.

15.1.3 CurrencyDigits (\textit{currency})

When the CurrencyDigits abstract operation is called with an argument \textit{currency} (which must be an upper case String value), the following steps are taken:

1. If the ISO 4217 currency and funds code list contains \textit{currency} as an alphabetic code, return the minor unit value corresponding to the \textit{currency} from the list; otherwise, return 2.
When a Number format function \( F \) is called with optional argument \( value \), the following steps are taken:

1. Let \( nf \) be \( F.\{\text{NumberFormat}\} \).
2. Assert: \( \text{Type}(nf) \) is Object and \( nf \) has an \( \{\text{InitializedNumberFormat}\} \) internal slot.
3. If \( value \) is not provided, let \( value \) be \( \text{undefined} \).
4. Let \( x \) be \( ? \, \text{ToNumeric}(value) \).
5. Return \( ? \, \text{FormatNumeric}(nf, x) \).

The "length" property of a Number format function is 1.

15.1.5 FormatNumericToString ( \( intlObject, x \) )

The FormatNumericToString abstract operation is called with arguments \( intlObject \) (which must be an object with \( \{\text{RoundingType}\}, \{\text{MinimumSignificantDigits}\}, \{\text{MaximumSignificantDigits}\}, \{\text{MinimumIntegerDigits}\}, \{\text{MinimumFractionDigits}\}, \{\text{MaximumFractionDigits}\} \) internal slots), and \( x \) (which must be a Number or BigInt value), and returns a Record containing two values: \( x \) as a String value with digits formatted according to the five formatting parameters in the field \( \{\text{FormattedString}\} \), and the final floating decimal value of \( x \) after rounding has been performed in the field \( \{\text{RoundedNumber}\} \).

1. If \( x < 0 \) or \( x \) is \( -0 \) \( \mathbb{F} \), let \( \text{isNegative} \) be \( \text{true} \); else let \( \text{isNegative} \) be \( \text{false} \).
2. If \( \text{isNegative} \), then
   a. Let \( x \) be \( -x \).
3. If \( intlObject.\{\text{RoundingType}\} \) is \( \text{significantDigits} \), then
   a. Let \( result \) be \( \text{ToRawPrecision}(x, intlObject.\{\text{MinimumSignificantDigits}\}, intlObject.\{\text{MaximumSignificantDigits}\}) \).
4. Else if \( intlObject.\{\text{RoundingType}\} \) is \( \text{fractionDigits} \), then
   a. Let \( result \) be \( \text{ToRawFixed}(x, intlObject.\{\text{MinimumFractionDigits}\}, intlObject.\{\text{MaximumFractionDigits}\}) \).
5. Else,
   a. Assert: \( intlObject.\{\text{RoundingType}\} \) is \( \text{compactRounding} \).
   b. Let \( result \) be \( \text{ToRawPrecision}(x, 1, 2) \).
   c. If \( result.\{\text{IntegerDigitsCount}\} > 1 \), then
      i. Let \( result \) be \( \text{ToRawFixed}(x, 0, 0) \).
6. Let \( x \) be \( result.\{\text{RoundedNumber}\} \).
7. Let \( \text{string} \) be \( result.\{\text{FormattedString}\} \).
8. Let \( \text{int} \) be \( result.\{\text{IntegerDigitsCount}\} \).
9. Let \( \text{minInteger} \) be \( intlObject.\{\text{MinimumIntegerDigits}\} \).
10. If \( \text{int} < \text{minInteger} \), then
    a. Let \( \text{forwardZeros} \) be the String consisting of \( \text{minInteger}−\text{int} \) occurrences of the character "0".
    b. Set \( \text{string} \) to the string-concatenation of \( \text{forwardZeros} \) and \( \text{string} \).
11. If \( \text{isNegative} \), then
    a. Let \( x \) be \( -x \).
12. Return the Record \{ \[\text{RoundedNumber}\]: \( x \), \[\text{FormattedString}\]: \( \text{string} \) \}.

15.1.6 PartitionNumberPattern ( \( numberFormat, x \) )

The PartitionNumberPattern abstract operation is called with arguments \( numberFormat \) (which must be an object initialized as a NumberFormat) and \( x \) (which must be a Number or BigInt value), interprets \( x \) as a numeric value, and creates the corresponding parts according to the effective locale and the formatting options of \( numberFormat \). The following steps are taken:

1. Let \( \text{exponent} \) be 0.
2. If \( x \) is \( \text{NaN} \), then
   a. Let \( n \) be an implementation- and locale-dependent (ILD) String value indicating the 
      \( \text{NaN} \) value.
3. Else if \( x \) is a non-finite Number, then
   a. Let \( n \) be an ILD String value indicating infinity.
4. Else,
   a. If \( \text{numberFormat.}[[\text{Style}]] \) is "percent", let \( x \) be \( 100 \times x \).
   b. Let \( \text{exponent} \) be \( \text{ComputeExponent(} \text{numberFormat}, \ x \text{)} \).
   c. Let \( x \) be \( x \times 10^{-\text{exponent}} \).
   d. Let \( \text{formatNumberResult} \) be \( \text{FormatNumericToString(} \text{numberFormat}, \ x \text{)} \).
   e. Let \( n \) be \( \text{formatNumberResult.}[[\text{FormattedString}]] \).
   f. Let \( x \) be \( \text{formatNumberResult.}[[\text{RoundedNumber}]] \).
5. Let \( \text{pattern} \) be \( \text{GetNumberFormatPattern(} \text{numberFormat}, \ x \text{)} \).
6. Let \( \text{result} \) be a new empty List.
7. Let \( \text{patternParts} \) be \( \text{PartitionPattern(} \text{pattern} \text{)} \).
8. For each Record \{ [[Type]], [[Value]] \} \( \text{patternPart} \) of \( \text{patternParts} \), do
   a. Let \( p \) be \( \text{patternPart.}[[\text{Type}]] \).
   b. If \( p \) is "literal", then
      i. Append a new Record \{ [[Type]]: "literal", [[Value]]: \( \text{patternPart.}[[\text{Value}]] \} \) as the 
         last element of \( \text{result} \).
   c. Else if \( p \) is equal to "number", then
      i. Let \( \text{notationSubParts} \) be \( \text{PartitionNotationSubPattern(} \text{numberFormat}, \ x, \ n, \ \text{exponent} \text{)} \).
      ii. Append all elements of \( \text{notationSubParts} \) to \( \text{result} \).
   d. Else if \( p \) is equal to "plusSign", then
      i. Let \( \text{plusSignSymbol} \) be the ILND String representing the plus sign.
      ii. Append a new Record \{ [[Type]]: "plusSign", [[Value]]: \( \text{plusSignSymbol} \} \) as the 
          last element of \( \text{result} \).
   e. Else if \( p \) is equal to "minusSign", then
      i. Let \( \text{minusSignSymbol} \) be the ILND String representing the minus sign.
      ii. Append a new Record \{ [[Type]]: "minusSign", [[Value]]: \( \text{minusSignSymbol} \} \) as the 
           last element of \( \text{result} \).
   f. Else if \( p \) is equal to "percentSign" and \( \text{numberFormat.}[[\text{Style}]] \) is "percent", then
      i. Let \( \text{percentSignSymbol} \) be the ILND String representing the percent sign.
      ii. Append a new Record \{ [[Type]]: "percentSign", [[Value]]: \( \text{percentSignSymbol} \} \) as the 
           last element of \( \text{result} \).
   g. Else if \( p \) is equal to "unitPrefix" and \( \text{numberFormat.}[[\text{Style}]] \) is "unit", then
      i. Let \( \text{unit} \) be \( \text{numberFormat.}[[\text{Unit}]] \).
      ii. Let \( \text{unitDisplay} \) be \( \text{numberFormat.}[[\text{UnitDisplay}]] \).
      iii. Let \( \mu \) be an ILD String value representing \( \text{unit} \) before \( x \) in \( \text{unitDisplay} \) form, 
           which may depend on \( x \) in languages having different plural forms.
      iv. Append a new Record \{ [[Type]]: "unit", [[Value]]: \( \mu \} \) as the last element of 
           \( \text{result} \).
   h. Else if \( p \) is equal to "unitSuffix" and \( \text{numberFormat.}[[\text{Style}]] \) is "unit", then
      i. Let \( \text{unit} \) be \( \text{numberFormat.}[[\text{Unit}]] \).
      ii. Let \( \text{unitDisplay} \) be \( \text{numberFormat.}[[\text{UnitDisplay}]] \).
      iii. Let \( \mu \) be an ILD String value representing \( \text{unit} \) after \( x \) in \( \text{unitDisplay} \) form, which 
           may depend on \( x \) in languages having different plural forms.
      iv. Append a new Record \{ [[Type]]: "unit", [[Value]]: \( \mu \} \) as the last element of 
           \( \text{result} \).
   i. Else if \( p \) is equal to "currencyCode" and \( \text{numberFormat.}[[\text{Style}]] \) is "currency", then
      i. Let \( \text{currency} \) be \( \text{numberFormat.}[[\text{Currency}]] \).
      ii. Let \( \text{cd} \) be \( \text{currency} \).
      iii. Append a new Record \{ [[Type]]: "currency", [[Value]]: \( \text{cd} \} \) as the last element of 
            \( \text{result} \).
j. Else if \( p \) is equal to "currencyPrefix" and \( \text{numberFormat}.[[\text{Style}]] \) is "currency", then
   i. Let \( \text{currency} \) be \( \text{numberFormat}.[[\text{Currency}]] \).
   ii. Let \( \text{currencyDisplay} \) be \( \text{numberFormat}.[[\text{CurrencyDisplay}]] \).
   iii. Let \( cd \) be an ILD String value representing \( \text{currency} \) before \( x \) in \( \text{currencyDisplay} \) form, which may depend on \( x \) in languages having different plural forms.
   iv. Append a new \( \text{Record} \) \( [[\text{Type}]]: "\text{currency}" \), \( [[\text{Value}]]: \) \( cd \) ] as the last element of \( \text{result} \).

k. Else if \( p \) is equal to "currencySuffix" and \( \text{numberFormat}.[[\text{Style}]] \) is "currency", then
   i. Let \( \text{currency} \) be \( \text{numberFormat}.[[\text{Currency}]] \).
   ii. Let \( \text{currencyDisplay} \) be \( \text{numberFormat}.[[\text{CurrencyDisplay}]] \).
   iii. Let \( cd \) be an ILD String value representing \( \text{currency} \) after \( x \) in \( \text{currencyDisplay} \) form, which may depend on \( x \) in languages having different plural forms. If the implementation does not have such a representation of \( \text{currency} \), use \( \text{currency} \) itself.
   iv. Append a new \( \text{Record} \) \( [[\text{Type}]]: "\text{currency}" \), \( [[\text{Value}]]: \) \( cd \) ] as the last element of \( \text{result} \).

   i. Let \( \text{unknown} \) be an ILND String based on \( x \) and \( p \).
   ii. Append a new \( \text{Record} \) \( [[\text{Type}]]: "\text{unknown}" \), \( [[\text{Value}]]: \) \( \text{unknown} \) ] as the last element of \( \text{result} \).

9. Return \( \text{result} \).

15.1.7 PartitionNotationSubPattern ( \( \text{numberFormat}, x, n, \text{exponent} \) )

The PartitionNotationSubPattern abstract operation is called with arguments \( \text{numberFormat} \) (which must be an object initialized as a NumberFormat), \( x \) (which is a numeric value after rounding is applied), \( n \) (which is an intermediate formatted string), and \( \text{exponent} \) (an integer), and creates the corresponding parts for the number and notation according to the effective locale and the formatting options of \( \text{numberFormat} \). The following steps are taken:

1. Let \( \text{result} \) be a new empty \( \text{List} \).
2. If \( x \) is \( \text{NaN} \), then
   a. Append a new \( \text{Record} \) \( [[\text{Type}]]: "\text{nan}" \), \( [[\text{Value}]]: \) \( n \) ] as the last element of \( \text{result} \).
3. Else if \( x \) is a non-finite Number, then
   a. Append a new \( \text{Record} \) \( [[\text{Type}]]: "\text{infinity}" \), \( [[\text{Value}]]: \) \( n \) ] as the last element of \( \text{result} \).
4. Else,
   a. Let \( \text{notationSubPattern} \) be \( \text{GetNotationSubPattern}(\text{numberFormat}, \text{exponent}) \).
   b. Let \( \text{patternParts} \) be \( \text{PartitionPattern}(\text{notationSubPattern}) \).
   c. For each \( \text{Record} \) \( [[\text{Type}]], [[\text{Value}]] \) of \( \text{patternParts} \), do
      i. Let \( p \) be \( \text{patternPart}.[[\text{Type}]] \).
      ii. If \( p \) is "literal", then
         1. Append a new \( \text{Record} \) \( [[\text{Type}]]: "\text{literal}" \), \( [[\text{Value}]]: \) \( \text{patternPart}.[[\text{Value}]] \) ] as the last element of \( \text{result} \).
      iii. Else if \( p \) is equal to "number", then
         1. If the \( \text{numberFormat}.[[\text{NumberingSystem}]] \) matches one of the values in the "Numbering System" column of Table 10 below, then
            a. Let \( \text{digits} \) be a \( \text{List} \) whose 10 String valued elements are the UTF-16 string representations of the 10 digits specified in the "Digits" column of the matching row in Table 10.
            b. Replace each \( \text{digit} \) in \( n \) with the value of \( \text{digits}[\text{digit}] \).
         2. Else use an implementation dependent algorithm to map \( n \) to the appropriate representation of \( n \) in the given numbering system.
         3. Let \( \text{decimalSepIndex} \) be \( ! \text{StringIndexOf}(n, "", 0) \).
         4. If \( \text{decimalSepIndex} > 0 \), then
            a. Append a new \( \text{Record} \) \( [[\text{Type}]]: "\text{number}" \), \( [[\text{Value}]]: \) \( n \) ] as the last element of \( \text{result} \).
   d. For each remaining \( \text{Record} \) \( [[\text{Type}]], [[\text{Value}]] \) of \( \text{patternParts} \), do
      i. Let \( p \) be \( \text{patternPart}.[[\text{Type}]] \).
      ii. If \( p \) is "literal", then
         1. Append a new \( \text{Record} \) \( [[\text{Type}]]: "\text{literal}" \), \( [[\text{Value}]]: \) \( \text{patternPart}.[[\text{Value}]] \) ] as the last element of \( \text{result} \).
      iii. Else if \( p \) is equal to "number", then
         1. If the \( \text{numberFormat}.[[\text{NumberingSystem}]] \) matches one of the values in the "Numbering System" column of Table 10 below, then
            a. Let \( \text{digits} \) be a \( \text{List} \) whose 10 String valued elements are the UTF-16 string representations of the 10 digits specified in the "Digits" column of the matching row in Table 10.
            b. Replace each \( \text{digit} \) in \( n \) with the value of \( \text{digits}[\text{digit}] \).
         2. Else use an implementation dependent algorithm to map \( n \) to the appropriate representation of \( n \) in the given numbering system.
         3. Let \( \text{decimalSepIndex} \) be \( ! \text{StringIndexOf}(n, "", 0) \).
         4. If \( \text{decimalSepIndex} > 0 \), then
            a. Append a new \( \text{Record} \) \( [[\text{Type}]]: "\text{number}" \), \( [[\text{Value}]]: \) \( n \) ] as the last element of \( \text{result} \).
   e. Replace each remaining \( \text{Record} \) \( [[\text{Type}]], [[\text{Value}]] \) of \( \text{patternParts} \), do
      i. Let \( p \) be \( \text{patternPart}.[[\text{Type}]] \).
      ii. If \( p \) is "literal", then
         1. Append a new \( \text{Record} \) \( [[\text{Type}]]: "\text{literal}" \), \( [[\text{Value}]]: \) \( \text{patternPart}.[[\text{Value}]] \) ] as the last element of \( \text{result} \).
      iii. Else if \( p \) is equal to "number", then
         1. If the \( \text{numberFormat}.[[\text{NumberingSystem}]] \) matches one of the values in the "Numbering System" column of Table 10 below, then
            a. Let \( \text{digits} \) be a \( \text{List} \) whose 10 String valued elements are the UTF-16 string representations of the 10 digits specified in the "Digits" column of the matching row in Table 10.
            b. Replace each \( \text{digit} \) in \( n \) with the value of \( \text{digits}[\text{digit}] \).
         2. Else use an implementation dependent algorithm to map \( n \) to the appropriate representation of \( n \) in the given numbering system.
a. Let `integer` be the substring of `n` from position 0, inclusive, to position `decimalSepIndex`, exclusive.
b. Let `fraction` be the substring of `n` from position `decimalSepIndex`, exclusive, to the end of `n`.

5. Else,
   a. Let `integer` be `n`.
   b. Let `fraction` be `undefined`.

6. If the `numberFormat`.[[UseGrouping]] is `true`, then
   a. Let `groupSepSymbol` be the implementation-, locale-, and numbering system-dependent (ILND) String representing the grouping separator.
   b. Let `groups` be a List whose elements are, in left to right order, the substrings defined by ILND set of locations within the `integer`.
   c. Assert: The number of elements in `groups` List is greater than 0.
   d. Repeat, while `groups` List is not empty,
      i. Remove the first element from `groups` and let `integerGroup` be the value of that element.
      ii. Append a new Record `[[Type]]: "integer", [[Value]]: `integerGroup` } as the last element of `result`.
      iii. If `groups` List is not empty, then
          i. Append a new Record `[[Type]]: "group", [[Value]]: `groupSepSymbol` } as the last element of `result`.
   7. Else,
      a. Append a new Record `[[Type]]: "integer", [[Value]]: `integer` } as the last element of `result`.

8. If `fraction` is not `undefined`, then
   a. Let `decimalSepSymbol` be the ILND String representing the decimal separator.
   b. Append a new Record `[[Type]]: "decimal", [[Value]]: `decimalSepSymbol` } as the last element of `result`.
   c. Append a new Record `[[Type]]: "fraction", [[Value]]: `fraction` } as the last element of `result`.
iv. Else if `p` is equal to "compactSymbol", then
   1. Let `compactSymbol` be an ILD string representing `exponent` in short form, which may depend on `x` in languages having different plural forms. The implementation must be able to provide this string, or else the pattern would not have a "[compactSymbol]" placeholder.
   2. Append a new Record `[[Type]]: "compact", [[Value]]: `compactSymbol` } as the last element of `result`.
v. Else if `p` is equal to "compactName", then
   1. Let `compactName` be an ILD string representing `exponent` in long form, which may depend on `x` in languages having different plural forms. The implementation must be able to provide this string, or else the pattern would not have a "[compactName]" placeholder.
   2. Append a new Record `[[Type]]: "compact", [[Value]]: `compactName` } as the last element of `result`.
vi. Else if `p` is equal to "scientificSeparator", then
   1. Let `scientificSeparator` be the ILND String representing the exponent separator.
   2. Append a new Record `[[Type]]: "exponentSeparator", [[Value]]: `scientificSeparator` } as the last element of `result`.

vii. Else if `p` is equal to "scientificExponent", then
   1. If `exponent` < 0, then
      a. Let `minusSignSymbol` be the ILND String representing the minus sign.
b. Append a new Record { [[Type]]: "exponentMinusSign", [[Value]]: minusSignSymbol } as the last element of result.

c. Let exponent be -exponent.

2. Let exponentResult be ToRawFixed(exponent, 1, 0, 0).

3. Append a new Record { [[Type]]: "exponentInteger", [[Value]]: exponentResult.[[FormattedString]] } as the last element of result.

viii. Else,

1. Let unknown be an ILND String based on x and p.

2. Append a new Record { [[Type]]: "unknown", [[Value]]: unknown } as the last element of result.

5. Return result.

### NOTE 1
The computations rely on String values and locations within numeric strings that are dependent upon the implementation and the effective locale of `numberFormat` ("ILD") or upon the implementation, the effective locale, and the numbering system of `numberFormat` ("ILND"). The ILD and ILND Strings mentioned, other than those for currency names, must not contain any characters in the General Category "Number, decimal digit" as specified by the Unicode Standard.

### NOTE 2
It is recommended that implementations use the locale provided by the Common Locale Data Repository (available at http://cldr.unicode.org).

### 15.1.8 FormatNumeric ( `numberFormat, x` )

The FormatNumeric abstract operation is called with arguments `numberFormat` (which must be an object initialized as a NumberFormat) and `x` (which must be a Number or BigInt value), and performs the following steps:

1. Let `parts` be `PartitionNumberPattern(numberFormat, x)`.
2. Let `result` be the empty String.
3. For each Record `{[[Type]], [[Value]]} part in parts, do
   a. Set `result` to the string-concatenation of `result` and `part. [[Value]]`.
4. Return `result`.

### 15.1.9 FormatNumericToParts ( `numberFormat, x` )

The FormatNumericToParts abstract operation is called with arguments `numberFormat` (which must be an object initialized as a NumberFormat) and `x` (which must be a Number or BigInt value), and performs the following steps:

1. Let `parts` be `PartitionNumberPattern(numberFormat, x)`.
2. Let `result` be `ArrayCreate(0)`.
3. Let `n` be 0.
4. For each Record `{[[Type]], [[Value]]} part in parts, do
   a. Let `O` be `OrdinaryObjectCreate(%Object.prototype%)`.
   b. Perform ! `CreateDataPropertyOrThrow(O, "type", part. [[Type]])`.
   c. Perform ! `CreateDataPropertyOrThrow(O, "value", part. [[Value]])`.© Ecma International
Perform \( \text{CreateDataPropertyOrThrow}(\text{result}, \text{ToString}(n), O) \).

Increment \( n \) by 1.

5. Return \( \text{result} \).

15.1.10 ToRawPrecision \( (x, \text{minPrecision}, \text{maxPrecision}) \)

When the ToRawPrecision abstract operation is called with arguments \( x \) (which must be a finite non-negative Number or BigInt), \( \text{minPrecision} \), and \( \text{maxPrecision} \) (both must be integers between 1 and 21), the following steps are taken:

1. Let \( p \) be \( \text{maxPrecision} \).
2. If \( x = 0 \), then
   a. Let \( m \) be the String consisting of \( p \) occurrences of the character "0".
   b. Let \( e \) be 0.
   c. Let \( x\text{Final} \) be 0.
3. Else,
   a. Let \( e \) be the base 10 logarithm of \( x \) rounded down to the nearest integer.
   b. Let \( n \) be an integer such that \( 10^{p-1} \leq n < 10^p \) and for which the exact mathematical value of \( n \times 10^{e-p+1} - x \) is as close to zero as possible. If there is more than one such \( n \), pick the one for which \( n \times 10^{e-p+1} \) is larger.
   c. Let \( m \) be the String consisting of the digits of the decimal representation of \( n \) (in order, with no leading zeroes).
   d. Let \( x\text{Final} \) be \( n \times 10^{e-p+1} \).
4. If \( e \geq p-1 \), then
   a. Let \( m \) be the string-concatenation of \( m \) and \( e-p+1 \) occurrences of the character "0".
   b. Let \( \text{int} \) be \( e+1 \).
5. Else if \( e \geq 0 \), then
   a. Let \( m \) be the string-concatenation of the first \( e+1 \) characters of \( m \), the character ".", and the remaining \( p-(e+1) \) characters of \( m \).
   b. Let \( \text{int} \) be \( e+1 \).
6. Else,
   a. Assert: \( e < 0 \).
   b. Let \( m \) be the string-concatenation of the String value "0.", \( -(e+1) \) occurrences of the character "0", and \( m \).
   c. Let \( \text{int} \) be 1.
7. If \( m \) contains the character ".", and \( \text{maxPrecision} > \text{minPrecision} \), then
   a. Let \( \text{cut} \) be \( \text{maxPrecision} - \text{minPrecision} \).
   b. Repeat, while \( \text{cut} > 0 \) and the last character of \( m \) is "0",
      i. Remove the last character from \( m \).
      ii. Decrease \( \text{cut} \) by 1.
   c. If the last character of \( m \) is ",", then
      i. Remove the last character from \( m \).
8. Return the Record \{ [[FormattedString]]: \( m \), [[RoundedNumber]]: \( x\text{Final} \), [[IntegerDigitsCount]]: \( \text{int} \) \}.

15.1.11 ToRawFixed \( (x, \text{minInteger}, \text{minFraction}, \text{maxFraction}) \)

When the ToRawFixed abstract operation is called with arguments \( x \) (which must be a finite non-negative Number or BigInt), \( \text{minInteger} \) (which must be an integer between 1 and 21), \( \text{minFraction} \), and \( \text{maxFraction} \) (which must be integers between 0 and 20), the following steps are taken:

1. Let \( f \) be \( \text{maxFraction} \).
2. Let \( n \) be an integer for which the exact mathematical value of \( n \ / \ 10^f - x \) is as close to zero as possible. If there are two such \( n \), pick the larger \( n \).
3. Let $x_{\text{Final}}$ be $n / 10^f$.
4. If $n = 0$, let $m$ be the String "0". Otherwise, let $m$ be the String consisting of the digits of the decimal representation of $n$ (in order, with no leading zeroes).
5. If $f \neq 0$, then
   a. Let $k$ be the number of characters in $m$.
   b. If $k \leq f$, then
      i. Let $z$ be the String consisting of $f-k$ occurrences of the character "0".
      ii. Let $m$ be the string-concatenation of $z$ and $m$.
      iii. Let $k$ be $f+1$.
   c. Let $a$ be the first $k-f$ characters of $m$, and let $b$ be the remaining $f$ characters of $m$.
   d. Let $m$ be the string-concatenation of $a",","$, and $b$.
   e. Let $int$ be the number of characters in $a$.
6. Else, let $int$ be the number of characters in $m$.
7. Let $cut$ be $\maxFraction - \minFraction$.
8. Repeat, while $cut > 0$ and the last character of $m$ is "0",
   a. Remove the last character from $m$.
   b. Decrease $cut$ by 1.
9. If the last character of $m$ is ",", then
   a. Remove the last character from $m$.
10. Return the Record {[[FormattedString]]: $m$, [[RoundedNumber]]: $x_{\text{Final}}$, [[IntegerDigitsCount]]: $int$}.

15.1.12 UnwrapNumberFormat ($nf$)

The UnwrapNumberFormat abstract operation gets the underlying NumberFormat operation for various methods which implement ECMA-402 v1 semantics for supporting initializing existing Intl objects.

1. **Assert**: Type($nf$) is Object.

   **NORMATIVE OPTIONAL**

   2. If $nf$ does not have an [[InitializedNumberFormat]] internal slot and
      ? OrdinaryHasInstance(%NumberFormat%, $nf$) is true, then
      a. Let $nf$ be ? Get($nf$, %Intl%.[[FallbackSymbol]]).

   3. Perform ? RequireInternalSlot($nf$, [[InitializedNumberFormat]]).
   4. Return $nf$.

   **NOTE** See 8.2 Note 1 for the motivation of the normative optional text.

15.1.13 SetNumberFormatUnitOptions ($intlObj$, $options$)

The abstract operation SetNumberFormatUnitOptions resolves the user-specified options relating to units onto the Intl object.

1. **Assert**: Type($intlObj$) is Object.
2. **Assert**: Type($options$) is Object.
4. Set $intlObj$.[[Style]] to $style$.
6. If $currency$ is undefined, then
   a. If $style$ is "currency", throw a TypeError exception.
7. Else,
   a. If the result of IsWellFormedCurrencyCode(currency) is false, throw a RangeError exception.
11. If unit is undefined, then
    a. If style is "unit", throw a TypeError exception.
12. Else,
    a. If the result of IsWellFormedUnitIdentifier(unit) is false, throw a RangeError exception.
14. If style is "currency", then
    a. Let currency be the result of converting currency to upper case as specified in 6.1.
    b. Set intlObj.[[Currency]] to currency.
    c. Set intlObj.[[CurrencyDisplay]] to currencyDisplay.
    d. Set intlObj.[[CurrencySign]] to currencySign.
15. If style is "unit", then
    a. Set intlObj.[[Unit]] to unit.
    b. Set intlObj.[[UnitDisplay]] to unitDisplay.

15.1.14 GetNumberFormatPattern ( numberFormat, x )

The abstract operation GetNumberFormatPattern considers the resolved unit-related options in the number format object along with the final scaled and rounded number being formatted and returns a pattern, a String value as described in 15.3.3.

1. Let localeData be %NumberFormat%.[[LocaleData]].
2. Let dataLocale be numberFormat.[[DataLocale]].
3. Let dataLocaleData be localeData.[[<dataLocales>]].
4. Let patterns be dataLocaleData.[[patterns]].
5. Assert: patterns is a Record (see 15.3.3).
6. Let style be numberFormat.[[Style]].
7. If style is "percent", then
   a. Let patterns be patterns.[[percent]].
8. Else if style is "unit", then
   a. Let unit be numberFormat.[[Unit]].
   b. Let unitDisplay be numberFormat.[[UnitDisplay]].
   c. Let patterns be patterns.[[unit]].
   d. If patterns doesn’t have a field [[<unit>]], then
      i. Let unit be "fallback".
   e. Let patterns be patterns.[[<unit>]].
   f. Let patterns be patterns.[[<unitDisplay>]].
9. Else if style is "currency", then
   a. Let currency be numberFormat.[[Currency]].
   b. Let currencyDisplay be numberFormat.[[CurrencyDisplay]].
   c. Let currencySign be numberFormat.[[CurrencySign]].
   d. Let patterns be patterns.[[currency]].
   e. If patterns doesn’t have a field [[<currency>]], then
      i. Let currency be "fallback".
   f. Let patterns be patterns.[[<currency>]].
   g. Let patterns be patterns.[[<currencyDisplay>]].
   h. Let patterns be patterns.[[<currencySign>]].
10. Else,
   a. Assert: style is "decimal".
   b. Let patterns be patterns.[[decimal]].
11. Let signDisplay be numberFormat.[[SignDisplay]].
12. If signDisplay is "never", then
   a. Let pattern be patterns.[[zeroPattern]].
13. Else if signDisplay is "auto", then
   a. If x is 0 or x > 0 or x is NaN, then
      i. Let pattern be patterns.[[zeroPattern]].
   b. Else,
      i. Let pattern be patterns.[[negativePattern]].
14. Else if signDisplay is "always", then
   a. If x is 0 or x > 0 or x is NaN, then
      i. Let pattern be patterns.[[positivePattern]].
   b. Else,
      i. Let pattern be patterns.[[negativePattern]].
15. Else,
   a. Assert: signDisplay is "exceptZero".
   b. If x is 0 or x is -0 or x is NaN, then
      i. Let pattern be patterns.[[zeroPattern]].
   c. Else if x > 0, then
      i. Let pattern be patterns.[[positivePattern]].
   d. Else,
      i. Let pattern be patterns.[[negativePattern]].
16. Return pattern.

15.1.15 GetNotationSubPattern ( numberFormat, exponent )

The abstract operation GetNotationSubPattern considers the resolved notation and exponent, and
returns a String value for the notation sub pattern as described in 15.3.3.

1. Let localeData be %NumberFormat%.[[LocaleData]].
2. Let dataLocale be numberFormat.[[DataLocale]].
3. Let dataLocaleData be localeData.[[<dataLocale>]].
4. Let notationSubPatterns be dataLocaleData.[[notationSubPatterns]].
5. Assert: notationSubPatterns is a Record (see 15.3.3).
6. Let notation be numberFormat.[[Notation]].
7. If notation is "scientific" or notation is "engineering", then
   a. Return notationSubPatterns.[[scientific]].
8. Else if exponent is not 0, then
   a. Assert: notation is "compact".
   b. Let compactDisplay be numberFormat.[[CompactDisplay]].
   c. Let compactPatterns be notationSubPatterns.[[compact]].[[<compactDisplay>]].
   d. Return compactPatterns.[[<exponent>]].
9. Else,
   a. Return "{number}".

15.1.16 ComputeExponent ( numberFormat, x )

The abstract operation ComputeExponent computes an exponent (power of ten) by which to scale x
according to the number formatting settings. It handles cases such as 999 rounding up to 1000,
requiring a different exponent.

1. If x = 0, then
   a. Return 0.
2. If \( x < 0 \), then
   a. Let \( x = -x \).
3. Let \( \text{magnitude} \) be the base 10 logarithm of \( x \) rounded down to the nearest integer.
4. Let \( \text{exponent} \) be \( \text{ComputeExponentForMagnitude}(\text{numberFormat}, \text{magnitude}) \).
5. Let \( x = x \times 10^{-\text{exponent}} \).
6. Let \( \text{formatNumberResult} \) be \( \text{FormatNumericToString}(\text{numberFormat}, x) \).
7. If \( \text{formatNumberResult}[[\text{RoundedNumber}]] = 0 \), then
   a. Return \( \text{exponent} \).
8. Let \( \text{newMagnitude} \) be the base 10 logarithm of \( \text{formatNumberResult}[[\text{RoundedNumber}]] \) rounded down to the nearest integer.
9. If \( \text{newMagnitude} \) is \( \text{magnitude} - \text{exponent} \), then
   a. Return \( \text{exponent} \).
10. Return \( \text{ComputeExponentForMagnitude}(\text{numberFormat}, \text{magnitude} + 1) \).

### 15.1.17 ComputeExponentForMagnitude ( \( \text{numberFormat}, \text{magnitude} \) )

The abstract operation \( \text{ComputeExponentForMagnitude} \) computes an exponent by which to scale a number of the given magnitude (power of ten of the most significant digit) according to the locale and the desired notation (scientific, engineering, or compact).

1. Let \( \text{notation} \) be \( \text{numberFormat}.[[\text{Notation}]] \).
2. If \( \text{notation} \) is "standard", then
   a. Return 0.
3. Else if \( \text{notation} \) is "scientific", then
   a. Return \( \text{magnitude} \).
4. Else if \( \text{notation} \) is "engineering", then
   a. Let \( \text{thousands} \) be the greatest integer that is not greater than \( \text{magnitude} / 3 \).
   b. Return \( \text{thousands} \times 3 \).
5. Else,
   a. Assert: \( \text{notation} \) is "compact".
   b. Let \( \text{exponent} \) be an implementation- and locale-dependent (ILD) integer by which to scale a number of the given magnitude in compact notation for the current locale.
   c. Return \( \text{exponent} \).

### 15.2 The Intl.NumberFormat Constructor

The \( \text{NumberFormat} \) constructor is the \%NumberFormat\% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

#### 15.2.1 Intl.NumberFormat ( [ locales [ , options ] ] )

When the \( \text{Intl.NumberFormat} \) function is called with optional arguments \( \text{locales} \) and \( \text{options} \), the following steps are taken:

1. If \( \text{NewTarget} \) is \( \text{undefined} \), let \( \text{newTarget} \) be the active function object, else let \( \text{newTarget} \) be \( \text{NewTarget} \).
2. Let \( \text{numberFormat} \) be ? \( \text{ OrdinaryCreateFromConstructor)(\text{newTarget}, "%NumberFormat.prototype%","[[InitializedNumberFormat]], [[Locale]], [[DataLocale]], [[NumberingSystem]], [[Style]], [[Unit]], [[UnitDisplay]], [[Currency]], [[CurrencyDisplay]], [[CurrencySign]], [[MinimumIntegerDigits]], [[MinimumFractionDigits]], [[MaximumFractionDigits]], [[MinimumSignificantDigits]], [[MaximumSignificantDigits]], [[RoundingType]], [[Notation]], [[CompactDisplay]], [[UseGrouping]], [[SignDisplay]], [[BoundFormat]] »).

NORMATIVE OPTIONAL

4. Let this be the this value.
5. If NewTarget is undefined and ? OrdinaryHasInstance(%NumberFormat%, this) is true, then
   a. Perform ? DefinePropertyOrThrow(this, %Intl%.[[FallbackSymbol]],
   PropertyDescriptor{ [[Value]]: numberFormat, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }).
   b. Return this.

6. Return numberFormat.

NOTE See 8.2 Note 1 for the motivation of the normative optional text.

15.3 Properties of the Intl.NumberFormat Constructor

The Intl.NumberFormat constructor has the following properties:

15.3.1 Intl.NumberFormat.prototype

The value of Intl.NumberFormat.prototype is %NumberFormat.prototype%.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

15.3.2 Intl.NumberFormat.supportedLocalesOf (locales [, options ])

When the supportedLocalesOf method is called with arguments locales and options, the following steps are taken:

1. Let availableLocales be %NumberFormat%.[[AvailableLocales]].
2. Let requestedLocales be ? CanonicalizeLocaleList(locales).

The value of the "length" property of the supportedLocalesOf method is 1.

15.3.3 Internal slots

The value of the [[AvailableLocales]] internal slot is implementation-defined within the constraints described in 9.1.

The value of the [[RelevantExtensionKeys]] internal slot is « "nu" ».

NOTE 1 Unicode Technical Standard 35 describes two locale extension keys that are relevant to number formatting: "cu" for currency and "nu" for numbering system. Intl.NumberFormat, however, requires that the currency of a currency format is specified through the currency property in the options objects.

The value of the [[LocaleData]] internal slot is implementation-defined within the constraints described in 9.1 and the following additional constraints:

- The list that is the value of the "nu" field of any locale field of [[LocaleData]] must not include the values "native", "traditio", or "finance".
- `[[LocaleData]][[[locale]]]` must have a `[[patterns]]` field for all locale values `locale`. The value of this field must be a `Record`, which must have fields with the names of the four number format styles: "decimal", "percent", "currency", and "unit".

- The two fields "currency" and "unit" noted above must be Records with at least one field, "fallback". The "currency" may have additional fields with keys corresponding to currency codes according to 6.3. Each field of "currency" must be a `Record` with fields corresponding to the possible currencyDisplay values: "code", "symbol", "narrowSymbol", and "name". Each of those fields must contain a `Record` with fields corresponding to the possible currencySign values: "standard" or "accounting". The "unit" field (of `[[LocaleData]][[[locale]]]`) may have additional fields beyond the required field "fallback" with keys corresponding to core measurement unit identifiers corresponding to 6.5. Each field of "unit" must be a `Record` with fields corresponding to the possible unitDisplay values: "narrow", "short", and "long".

- All of the leaf fields so far described for the patterns tree ("decimal", "percent", great-grandchildren of "currency", and grandchildren of "unit") must be Records with the keys "positivePattern", "zeroPattern", and "negativePattern".

- The value of the aforementioned fields (the sign-dependent pattern fields) must be string values that must contain the substring "[number]". "positivePattern" must contain the substring "[plusSign]" but not "[minusSign]"; "negativePattern" must contain the substring "[minusSign]" but not "[plusSign]"; and "zeroPattern" must not contain either "[plusSign]" or "[minusSign]". Additionally, the values within the "percent" field must also contain the substring "[percentSign]"; the values within the "currency" field must also contain one or more of the following substrings: "[currencyCode]", "[currencyPrefix]", or "[currencySuffix]"; and the values within the "unit" field must also contain one or more of the following substrings: "[unitPrefix]" or "[unitSuffix]". The pattern strings must not contain any characters in the General Category "Number, decimal digit" as specified by the Unicode Standard.

- `[[LocaleData]][[[locale]]]` must also have a `[[notationSubPatterns]]` field for all locale values `locale`. The value of this field must be a `Record`, which must have two fields: `[[scientific]]` and `[[compact]]`. The `[[scientific]]` field must be a string value containing the substrings "[number]", "[scientificSeparator]", and "[scientificExponent]". The `[[compact]]` field must be a `Record` with two fields: "short" and "long". Each of these fields must be a `Record` with integer keys corresponding to all discrete magnitudes the implementation supports for compact notation. Each of these fields must be a string value which may contain the substring "[number]". Strings descended from "short" must contain the substring "[compactSymbol]", and strings descended from "long" must contain the substring "[compactName]".

**NOTE 2** It is recommended that implementations use the locale data provided by the Common Locale Data Repository (available at http://cldr.unicode.org).

### 15.4 Properties of the Intl.NumberFormat Prototype Object

The Intl.NumberFormat prototype object is itself an ordinary object. `%NumberFormat.prototype%` is not an Intl.NumberFormat instance and does not have an `[[InitializedNumberFormat]]` internal slot or any of the other internal slots of Intl.NumberFormat instance objects.

#### 15.4.1 Intl.NumberFormat.prototype.constructor

The initial value of `Intl.NumberFormat.prototype.constructor` is the intrinsic object `%NumberFormat%`.

#### 15.4.2 Intl.NumberFormat.prototype [ @@toStringTag ]

The initial value of the `@@toStringTag` property is the String value "Intl.NumberFormat".

© Ecma International 82
This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

15.4.3 get Intl.NumberFormat.prototype.format

Intl.NumberFormat.prototype.format is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let nf be the this value.
2. If Type(nf) is not Object, throw a TypeError exception.
3. Let nf be ? UnwrapNumberFormat(nf).
4. If nf.[[BoundFormat]] is undefined, then
   a. Let F be a new built-in function object as defined in Number Format Functions (15.1.4).
   b. Set F.[[NumberFormat]] to nf.
   c. Set nf.[[BoundFormat]] to F.
5. Return nf.[[BoundFormat]].

NOTE
The returned function is bound to nf so that it can be passed directly to Array.prototype.map or other functions. This is considered a historical artefact, as part of a convention which is no longer followed for new features, but is preserved to maintain compatibility with existing programs.

15.4.4 Intl.NumberFormat.prototype.formatToParts ( value )

When the formatToParts method is called with an optional argument value, the following steps are taken:

1. Let nf be the this value.
2. Perform ? RequireInternalSlot(nf, [[InitializedNumberFormat]]).
3. Let x be ? ToNumeric(value).
4. Return ? FormatNumericToParts(nf, x).

15.4.5 Intl.NumberFormat.prototype.resolvedOptions ( )

This function provides access to the locale and formatting options computed during initialization of the object.

1. Let nf be the this value.
2. If Type(nf) is not Object, throw a TypeError exception.
3. Let nf be ? UnwrapNumberFormat(nf).
4. Let options be ! OrdinaryObjectCreate(%Object.prototype%).
5. For each row of Table 11, except the header row, in table order, do
   a. Let p be the Property value of the current row.
   b. Let v be the value of nf’s internal slot whose name is the Internal Slot value of the current row.
   c. If v is not undefined, then
      i. Perform ! CreateDataPropertyOrThrow(options, p, v).
6. Return options.

Table 11: Resolved Options of NumberFormat Instances

<table>
<thead>
<tr>
<th>Internal Slot</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Locale]]</td>
<td>&quot;locale&quot;</td>
</tr>
<tr>

<td>&quot;numberingSystem&quot;</td>
</tr>
<tr>
<td>[[Style]]</td>
<td>&quot;style&quot;</td>
</tr>
</tbody>
</table>
15.5 Properties of Intl.NumberFormat Instances

Intl.NumberFormat instances are ordinary objects that inherit properties from %NumberFormat.prototype%.

Intl.NumberFormat instances have an [[InitializedNumberFormat]] internal slot.

Intl.NumberFormat instances also have several internal slots that are computed by the constructor:

- [[Locale]] is a String value with the language tag of the locale whose localization is used for formatting.
- [[DataLocale]] is a String value with the language tag of the nearest locale for which the implementation has data to perform the formatting operation. It will be a parent locale of [[Locale]].
- [[NumberingSystem]] is a String value with the "type" given in Unicode Technical Standard 35 for the numbering system used for formatting.
- [[Style]] is one of the String values "decimal", "currency", "percent", or "unit", identifying the type of quantity being measured.
- [[Currency]] is a String value with the currency code identifying the currency to be used if formatting with the "currency" unit type. It is only used when [[Style]] has the value "currency".
- [[CurrencyDisplay]] is one of the String values "code", "symbol", "narrowSymbol", or "name", specifying whether to display the currency as an ISO 4217 alphabetic currency code, a localized currency symbol, or a localized currency name if formatting with the "currency" style. It is only used when [[Style]] has the value "currency".
- [[CurrencySign]] is one of the String values "standard" or "accounting", specifying whether to render negative numbers in accounting format, often signified by parenthesis. It is only used when [[Style]] has the value "currency" and when [[SignDisplay]] is not "never".
• [[Unit]] is a core unit identifier, as defined by Unicode Technical Standard #35, Part 2, Section 6. It is only used when [[Style]] has the value "unit".
• [[UnitDisplay]] is one of the String values "short", "narrow", or "long", specifying whether to display the unit as a symbol, narrow symbol, or localized long name if formatting with the "unit" style. It is only used when [[Style]] has the value "unit".
• [[MinimumIntegerDigits]] is a non-negative integer Number value indicating the minimum integer digits to be used. Numbers will be padded with leading zeroes if necessary.
• [[MinimumFractionDigits]] and [[MaximumFractionDigits]] are non-negative integer Number values indicating the minimum and maximum fraction digits to be used. Numbers will be rounded or padded with trailing zeroes if necessary. These properties are only used when [[RoundingType]] is fractionDigits.
• [[MinimumSignificantDigits]] and [[MaximumSignificantDigits]] are positive integer Number values indicating the minimum and maximum fraction digits to be shown. If present, the formatter uses however many fraction digits are required to display the specified number of significant digits. These properties are only used when [[RoundingType]] is significantDigits.
• [[UseGrouping]] is a Boolean value indicating whether a grouping separator should be used.
• [[RoundingType]] is one of the values fractionDigits, significantDigits, or compactRounding, indicating which rounding strategy to use. If fractionDigits, the number is rounded according to [[MinimumFractionDigits]] and [[MaximumFractionDigits]], as described above. If significantDigits, the number is rounded according to [[MinimumSignificantDigits]] and [[MaximumSignificantDigits]] as described above. If compactRounding, the number is rounded to 1 maximum fraction digit if there is 1 digit before the decimal separator, and otherwise round to 0 fraction digits.
• [[Notation]] is one of the String values "standard", "scientific", "engineering", or "compact", specifying whether the number should be displayed without scaling, scaled to the units place with the power of ten in scientific notation, scaled to the nearest thousand with the power of ten in scientific notation, or scaled to the nearest locale-dependent compact decimal notation power of ten with the corresponding compact decimal notation affix.
• [[CompactDisplay]] is one of the String values "short" or "long", specifying whether to display compact notation affixes in short form ("5K") or long form ("5 thousand") if formatting with the "compact" notation. It is only used when [[Notation]] has the value "compact".
• [[SignDisplay]] is one of the String values "auto", "always", "never", or "exceptZero", specifying whether to show the sign on negative numbers only, positive and negative numbers including zero, neither positive nor negative numbers, or positive and negative numbers but not zero. In scientific notation, this slot affects the sign display of the mantissa but not the exponent.

Finally, Intl.NumberFormat instances have a [[BoundFormat]] internal slot that caches the function returned by the format accessor (15.4.3).

16 PluralRules Objects

16.1 Abstract Operations for PluralRules Objects

16.1.1 InitializePluralRules ( pluralRules, locales, options )

The abstract operation InitializePluralRules accepts the arguments pluralRules (which must be an object), locales, and options. It initializes pluralRules as a PluralRules object. The following steps are taken:

1. Let requestedLocales be ? CanonicalizeLocaleList(locales).
2. Set options to ? CoerceOptionsToObject(options).
3. Let opt be a new Record.

© Ecma International 85
When the GetOperands abstract operation is called with argument \( s \), it performs the following steps:

1. **Assert:** \( \text{Type}(s) \) is String.
2. Let \( n \) be \( ! \text{ToNumber}(s) \).
3. **Assert:** \( n \) is finite.
4. Let \( dp \) be \( ! \text{StringIndexOf}(s, ".", 0) \).
5. If \( dp = -1 \), then
   a. Set \( iv \) to \( n \).
   b. Let \( f \) be 0.
   c. Let \( v \) be 0.
6. Else,
   a. Let \( iv \) be the substring of \( s \) from position 0, inclusive, to position \( dp \), exclusive.
   b. Let \( fv \) be the substring of \( s \) from position \( dp \), exclusive, to the end of \( s \).
   c. Let \( f \) be \( ! \text{ToNumber}(fv) \).
   d. Let \( v \) be the length of \( fv \).
7. Let \( i \) be \( \text{abs}(! \text{ToNumber}(iv)) \).
8. If \( f \neq 0 \), then
   a. Let \( ft \) be the value of \( fv \) stripped of trailing "0".
   b. Let \( w \) be the length of \( ft \).
   c. Let \( t \) be \( ! \text{ToNumber}(ft) \).
9. Else,
   a. Let \( w \) be 0.
   b. Let \( t \) be 0.
10. Return a new \( \text{Record} \{ [[\text{Number}]]: n, [[\text{IntegerDigits}]]: i, [[\text{NumberOfFractionDigits}]]: v, [[\text{NumberOfFractionDigitsWithoutTrailing}]]: w, [[\text{FractionDigits}]]: f, [[\text{FractionDigitsWithoutTrailing}]]: t \} \).

**Table 12: Plural Rules Operands Record Fields**

<table>
<thead>
<tr>
<th>Internal Slot</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Number]]</td>
<td>Number</td>
<td>Absolute value of the source number (integer and decimals)</td>

<tr>
<td>[[FractionDigits]]</td>
<td>Number</td>
<td>Number of visible fractional digits in [[Number]], with trailing zeroes.</td>
</tr>
</tbody>
</table>
16.13 **PluralRuleSelect** (locale, type, n, operands)

When the PluralRuleSelect abstract operation is called with four arguments, it performs an implementation-dependent algorithm to map n to the appropriate plural representation of the Plural Rules Operands Record operands by selecting the rules denoted by type for the corresponding locale, or the String value "other".

16.14 **ResolvePlural** (pluralRules, n)

When the ResolvePlural abstract operation is called with arguments pluralRules (which must be an object initialized as a PluralRules) and n (which must be a Number value), it returns a String value representing the plural form of n according to the effective locale and the options of pluralRules. The following steps are taken:

1. Assert: Type(pluralRules) is Object.
2. Assert: pluralRules has an [[InitializedPluralRules]] internal slot.
3. Assert: Type(n) is Number.
4. If n is not a finite Number, then
   a. Return "other".
5. Let locale be pluralRules.[[Locale]].
6. Let type be pluralRules.[[Type]].
7. Let res be ! FormatNumericToString(pluralRules, n).
8. Let s be res.[[FormattedString]].
9. Let operands be ! GetOperands(s).
10. Return ! PluralRuleSelect(locale, type, n, operands).

16.2 The Intl.PluralRules Constructor

The PluralRules constructor is the %PluralRules% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

16.2.1 Intl.PluralRules ([ locales [, options ] ])

When the Intl.PluralRules function is called with optional arguments locales and options, the following steps are taken:

1. If NewTarget is undefined, throw a TypeError exception.
2. Let pluralRules be ? OrdinaryCreateFromConstructor(NewTarget, "%PluralRules.prototype%", « [[InitializedPluralRules]], [[Locale]], [[Type]], [[MinimumIntegerDigits]], [[MinimumFractionDigits]], [[MaximumFractionDigits]], [[MinimumSignificantDigits]], [[MaximumSignificantDigits]], [[RoundingType]] »).

16.3 Properties of the Intl.PluralRules Constructor

The Intl.PluralRules constructor has the following properties:
16.3.1 Intl.PluralRules.prototype

The value of Intl.PluralRules.prototype is %PluralRules.prototype%.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

16.3.2 Intl.PluralRules.supportedLocalesOf ( locales [, options ] )

When the supportedLocalesOf method is called with arguments locales and options, the following steps are taken:

1. Let availableLocales be %PluralRules%.[[AvailableLocales]].
2. Let requestedLocales be ?CanonicalizeLocaleList(locales).

The value of the "length" property of the supportedLocalesOf method is 1.

16.3.3 Internal slots

The value of the [[AvailableLocales]] internal slot is implementation-defined within the constraints described in 9.1.

The value of the [[RelevantExtensionKeys]] internal slot is « ».

NOTE 1 Unicode Technical Standard 35 describes no locale extension keys that are relevant to the pluralization process.

The value of the [[LocaleData]] internal slot is implementation-defined within the constraints described in 9.1.

NOTE 2 It is recommended that implementations use the locale data provided by the Common Locale Data Repository (available at http://cldr.unicode.org).

The Intl.PluralRules prototype object is itself an ordinary object. %PluralRules.prototype% is not an Intl.PluralRules instance and does not have an [[InitializedPluralRules]] internal slot or any of the other internal slots of Intl.PluralRules instance objects.

16.4.1 Intl.PluralRules.prototype.constructor

The initial value of Intl.PluralRules.prototype.constructor is the intrinsic object %PluralRules%.

16.4.2 Intl.PluralRules.prototype [ @@toStringTag ]

The initial value of the @@toStringTag property is the String value "Intl.PluralRules".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

16.4.3 Intl.PluralRules.prototype.select ( value )

When the select method is called with an argument value, the following steps are taken:
1. Let \( pr \) be the \texttt{this} value.
2. Perform \( ? \text{RequireInternalSlot}(pr, [[\text{InitializedPluralRules}]].) \).
3. Let \( n \) be \( ? \text{ToNumber}(value) \).
4. Return \( ! \text{ResolvePlural}(pr, n) \).

### 16.4.4 Intl.PluralRules.prototype.resolvedOptions ()

This function provides access to the locale and options computed during initialization of the object.

1. Let \( pr \) be the \texttt{this} value.
2. Perform \( ? \text{RequireInternalSlot}(pr, [[\text{InitializedPluralRules}]].) \).
3. Let \( options \) be \( ! \text{ OrdinaryObjectCreate}(%\text{Object.prototype}%) \).
4. For each row of Table 13, except the header row, in table order, do
   a. Let \( p \) be the Property value of the current row.
   b. Let \( v \) be the value of \( pr \)'s internal slot whose name is the Internal Slot value of the current row.
   c. If \( v \) is not \texttt{undefined}, then
      i. Perform \( ! \text{CreateDataPropertyOrThrow}(options, p, v) \).
5. Let \( pluralCategories \) be a List of Strings representing the possible results of \texttt{PluralRuleSelect} for the selected locale \( pr.[[\text{Locale}]]. \) This List consists of unique String values, from the the list "zero", "one", "two", "few", "many" and "other", that are relevant for the locale whose localization is specified in LDML Language Plural Rules.
6. Perform \( ! \text{CreateDataProperty}(options, "pluralCategories", CreateArrayFromList(pluralCategories)) \).
7. Return \( options \).

### Table 13: Resolved Options of PluralRules Instances

</table>

### 16.5 Properties of Intl.PluralRules Instances

Intl.PluralRules instances are ordinary objects that inherit properties from \%\texttt{PluralRules.prototype}%. Intl.PluralRules instances have an [[\text{InitializedPluralRules}]] internal slot.

Intl.PluralRules instances also have several internal slots that are computed by the constructor:

- [[Locale]] is a String value with the language tag of the locale whose localization is used by the plural rules.
- [[Type]] is one of the String values "cardinal" or "ordinal", identifying the plural rules used.
- [[MinimumIntegerDigits]] is a non-negative \texttt{integer} Number value indicating the minimum integer digits to be used.
- [[MinimumFractionDigits]] and [[MaximumFractionDigits]] are non-negative \texttt{integer} Number values indicating the minimum and maximum fraction digits to be used. Numbers will be
rounded or padded with trailing zeroes if necessary.

- [[MinimumSignificantDigits]] and [[MaximumSignificantDigits]] are positive integer Number values indicating the minimum and maximum fraction digits to be used. Either none or both of these properties are present; if they are, they override minimum and maximum integer and fraction digits.
- [[RoundingType]] is one of the values fractionDigits or significantDigits, indicating which rounding strategy to use, as discussed in 15.5.

17 RelativeTimeFormat Objects

17.1 Abstract Operations for RelativeTimeFormat Objects

17.1.1 InitializeRelativeTimeFormat ( relativeTimeFormat, locales, options )

The abstract operation InitializeRelativeTimeFormat accepts the arguments relativeTimeFormat (which must be an object), locales, and options. It initializes relativeTimeFormat as a RelativeTimeFormat object.

The following algorithm refers to UTS 35’s Unicode Language and Locale Identifiers grammar. The following steps are taken:

1. Let requestedLocales be ? CanonicalizeLocaleList(locales).
2. Set options to ? CoerceOptionsToObject(options).
3. Let opt be a new Record.
5. Set opt.[[LocaleMatcher]] to matcher.
7. If numberingSystem is not undefined, then
   a. If numberingSystem does not match the type sequence (from UTS 35 Unicode Locale Identifier, section 3.2), throw a RangeError exception.
8. Set opt.[[nu]] to numberingSystem.
9. Let localeData be %RelativeTimeFormat%.[[LocaleData]].
10. Let r be ResolveLocale(%RelativeTimeFormat%.[[AvailableLocales]], requestedLocales, opt, %RelativeTimeFormat%.[[AvailableLocales]], localeData).
11. Let locale be r.[[locale]].
12. Set relativeTimeFormat.[[Locale]] to locale.
13. Set relativeTimeFormat.[[DataLocale]] to r.[[dataLocale]].
14. Set relativeTimeFormat.[[NumberingSystem]] to r.[[nu]].
15. Let style be ? GetOption(options, "style", "string", «"long", "short", "narrow"», "long").
16. Set relativeTimeFormat.[[Style]] to style.
17. Let numeric be ? GetOption(options, "numeric", "string", «"always", "auto"", "always"»).
18. Set relativeTimeFormat.[[Numeric]] to numeric.
19. Let relativeTimeFormat.[[NumberFormat]] be ! Construct(%NumberFormat%, «locale»).
20. Let relativeTimeFormat.[[PluralRules]] be ! Construct(%PluralRules%, «locale»).

17.1.2 SingularRelativeTimeUnit ( unit )

1. Assert: Type(unit) is String.
2. If unit is "seconds", return "second".
3. If unit is "minutes", return "minute".
4. If unit is "hours", return "hour".
5. If `unit` is "days", return "day".
6. If `unit` is "weeks", return "week".
7. If `unit` is "months", return "month".
8. If `unit` is "quarters", return "quarter".
9. If `unit` is "years", return "year".
10. If `unit` is not one of "second", "minute", "hour", "day", "week", "month", "quarter", or "year", throw a `RangeError` exception.
11. Return `unit`.

17.1.3 PartitionRelativeTimePattern ( `relativeTimeFormat`, `value`, `unit` )

When the PartitionRelativeTimePattern abstract operation is called with arguments `relativeTimeFormat`, `value`, and `unit` it returns a String value representing `value` (which must be a `Number` value) according to the effective locale and the formatting options of `relativeTimeFormat`.

1. Assert: `relativeTimeFormat` has an `[[InitializedRelativeTimeFormat]]` internal slot.
2. Assert: `Type(value)` is `Number`.
3. Assert: `Type(unit)` is `String`.
4. If `value` is `NaN`, `+∞𝔽`, or `-∞𝔽`, throw a `RangeError` exception.
5. Let `unit` be ? SingularRelativeTimeUnit(`unit`).
6. Let `localeData` be `%RelativeTimeFormat%.[[LocaleData]]`.
7. Let `dataLocale` be `relativeTimeFormat`.[[DataLocale]].
8. Let `fields` be `localeData`.[[<dataLocale>]].
9. Let `style` be `relativeTimeFormat`.[[Style]].
10. If `style` is equal to "short", then
    a. Let `entry` be the string-concatenation of `unit` and "-short".
11. Else if `style` is equal to "narrow", then
    a. Let `entry` be the string-concatenation of `unit` and "-narrow".
12. Else,
    a. Let `entry` be `unit`.
13. If `fields` doesn't have a field `[[<entry>]]`, then
    a. Let `entry` be `unit`.
14. Let `patterns` be `fields`.[[<entry>]].
15. Let `numeric` be `relativeTimeFormat`.[[Numeric]].
16. If `numeric` is equal to "auto", then
    a. Let `valueString` be `ToString(value)`.
    b. If `patterns` has a field `[[<valueString>]]`, then
        i. Let `result` be `patterns`.[[<valueString>]].
        ii. Return a `List` containing the `Record` `[[Type]]: "literal", [[Value]]: `result` `}`.
17. If `value` is `-0𝔽` or if `value` is less than 0, then
    a. Let `tl` be "past".
18. Else,
    a. Let `tl` be "future".
19. Let `po` be `patterns`.[[<tl>]].
20. Let `fo` be ! PartitionNumberPattern(`relativeTimeFormat`.[[NumberFormat]], `value`).
22. Let `pattern` be `po`.[[<pr>]].
23. Return ! MakePartsList(`pattern`, `unit`, `fo`).

17.1.4 MakePartsList ( `pattern`, `unit`, `parts` )

The MakePartsList abstract operation is called with arguments `pattern`, a pattern String, `unit`, a String, and `parts`, a `List` of Records representing a formatted Number.
NOTE

1. Let \( \text{patternParts} \) be \( \text{PartitionPattern}(\text{pattern}) \).
2. Let \( \text{result} \) be a new empty List.
3. For each Record \([ \text{[Type]}, \text{[Value]} ]\) \( \text{patternPart} \) in \( \text{patternParts} \), do
   a. If \( \text{patternPart}.\text{[Type]} \) is "literal", then
      i. Append Record \([ \text{[Type]}: \text{"literal"}, \text{[Value]}: \text{patternPart}.\text{[Value]}, \text{[Unit]}: \text{empty} ]\) to \( \text{result} \).
   b. Else,
      i. Assert: \( \text{patternPart}.\text{[Type]} \) is "0".
      ii. For each Record \([ \text{[Type]}, \text{[Value]} ]\) \( \text{part} \) in \( \text{parts} \), do
          1. Append Record \([ \text{[Type]}: \text{part}.\text{[Type]}, \text{[Value]}: \text{part}.\text{[Value]}, \text{[Unit]}: \text{unit} ]\) to \( \text{result} \).
4. Return \( \text{result} \).

17.1.5 \ FormatRelativeTime \( (\text{relativeTimeFormat}, \text{value}, \text{unit}) \)

The FormatRelativeTime abstract operation is called with arguments \( \text{relativeTimeFormat} \) (which must be an object initialized as a RelativeTimeFormat), \( \text{value} \) (which must be a Number value), and \( \text{unit} \) (which must be a String denoting the value unit) and performs the following steps:

1. Let \( \text{parts} \) be ? \( \text{PartitionRelativeTimePattern}(\text{relativeTimeFormat}, \text{value}, \text{unit}) \).
2. Let \( \text{result} \) be an empty String.
3. For each Record \([ \text{[Type]}, \text{[Value]}, \text{[Unit]} ]\) \( \text{part} \) in \( \text{parts} \), do
   a. Set \( \text{result} \) to the string-concatenation of \( \text{result} \) and \( \text{part}.\text{[Value]} \).
4. Return \( \text{result} \).

17.1.6 \ FormatRelativeTimeToParts \( (\text{relativeTimeFormat}, \text{value}, \text{unit}) \)

The FormatRelativeTimeToParts abstract operation is called with arguments \( \text{relativeTimeFormat} \) (which must be an object initialized as a RelativeTimeFormat), \( \text{value} \) (which must be a Number value), and \( \text{unit} \) (which must be a String denoting the value unit) and performs the following steps:

1. Let \( \text{parts} \) be ? \( \text{PartitionRelativeTimePattern}(\text{relativeTimeFormat}, \text{value}, \text{unit}) \).
2. Let \( \text{result} \) be ArrayCreate(0).
3. Let \( n \) be 0.
4. For each Record \([ \text{[Type]}, \text{[Value]}, \text{[Unit]} ]\) \( \text{part} \) in \( \text{parts} \), do
   a. Let \( O \) be OrdinaryObjectCreate(%Object.prototype%).
   b. Perform ! \( \text{CreateDataPropertyOrThrow}(O, \text{"type"}, \text{part}.\text{[Type]}) \).
   c. Perform ! \( \text{CreateDataPropertyOrThrow}(O, \text{"value"}, \text{part}.\text{[Value]}) \).
   d. If \( \text{part}.\text{[Unit]} \) is not empty, then
      i. Perform ! \( \text{CreateDataPropertyOrThrow}(O, \text{"unit"}, \text{part}.\text{[Unit]}) \).
   e. Perform ! \( \text{CreateDataPropertyOrThrow}(\text{result}, ! \text{ToString}(n), O) \).
   f. Increment \( n \) by 1.
5. Return \( \text{result} \).
17.2 The Intl.RelativeTimeFormat Constructor

The RelativeTimeFormat constructor is the %RelativeTimeFormat% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

17.2.1 Intl.RelativeTimeFormat ([ locales [, options ] ])

When the Intl.RelativeTimeFormat function is called with optional arguments locales and options, the following steps are taken:

1. If NewTarget is undefined, throw a TypeError exception.
2. Let relativeTimeFormat be ? OrdinaryCreateFromConstructor(NewTarget, "%RelativeTimeFormat.prototype%", [[InitializedRelativeTimeFormat]], [[Locale]], [[DataLocale]], [[Style]], [[Numeric]], [[NumberFormat]], [[NumberingSystem]], [[PluralRules]]).

17.3 Properties of the Intl.RelativeTimeFormat Constructor

The Intl.RelativeTimeFormat constructor has the following properties:

17.3.1 Intl.RelativeTimeFormat.prototype

The value of Intl.RelativeTimeFormat.prototype is %RelativeTimeFormat.prototype%.

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

17.3.2 Intl.RelativeTimeFormat.supportedLocalesOf ( locales [, options ] )

When the supportedLocalesOf method of %RelativeTimeFormat% is called, the following steps are taken:

1. Let availableLocales be %RelativeTimeFormat%.[[AvailableLocales]].
2. Let requestedLocales be ? CanonicalizeLocaleList(locales).

The value of the "length" property of the supportedLocalesOf method is 1.

17.3.3 Internal slots

The value of the [[AvailableLocales]] internal slot is implementation-defined within the constraints described in 9.1.

The value of the [[RelevantExtensionKeys]] internal slot is « "nu" ».

NOTE 1 Unicode Technical Standard 35 describes one locale extension key that is relevant to relative time formatting: "nu" for numbering system (of formatted numbers).

The value of the [[LocaleData]] internal slot is implementation-defined within the constraints described in 9.1 and the following additional constraints, for all locale values locale:

- [[LocaleData]][locale] has fields "second", "minute", "hour", "day", "week", "month", "quarter", and "year". Additional fields may exist with the previous names concatenated with
the strings "-narrow" or "-short". The values corresponding to these fields are Records which contain these two categories of fields:
  - "future" and "past" fields, which are Records with a field for each of the plural categories relevant for locale. The value corresponding to those fields is a pattern which may contain "0" to be replaced by a formatted number.
  - Optionally, additional fields whose key is the result of ToString of a Number, and whose values are literal Strings which are not treated as templates.

- The list that is the value of the "nu" field of any locale field of [[LocaleData]] must not include the values "native", "traditio", or "finance".

**NOTE 2** It is recommended that implementations use the locale data provided by the Common Locale Data Repository (available at [http://cldr.unicode.org/](http://cldr.unicode.org/)).

### 17.4 Properties of the Intl.RelativeTimeFormat Prototype Object

The Intl.RelativeTimeFormat prototype object is itself an ordinary object. %RelativeTimeFormat.prototype% is not an Intl.RelativeTimeFormat instance and does not have an [[InitializedRelativeTimeFormat]] internal slot or any of the other internal slots of Intl.RelativeTimeFormat instance objects.

#### 17.4.1 Intl.RelativeTimeFormat.prototype.constructor

The initial value of Intl.RelativeTimeFormat.prototype.constructor is %RelativeTimeFormat%.

#### 17.4.2 Intl.RelativeTimeFormat.prototype[ @@toStringTag ]

The initial value of the @@toStringTag property is the String value "Intl.RelativeTimeFormat". This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

#### 17.4.3 Intl.RelativeTimeFormat.prototype.format ( value, unit )

When the format method is called with arguments value and unit, the following steps are taken:

1. Let relativeTimeFormat be the this value.
2. Perform ? RequireInternalSlot(relativeTimeFormat, [[InitializedRelativeTimeFormat]]).
3. Let value be ? ToNumber(value).
4. Let unit be ? ToString(unit).

#### 17.4.4 Intl.RelativeTimeFormat.prototype.formatToParts ( value, unit )

When the formatToParts method is called with arguments value and unit, the following steps are taken:

1. Let relativeTimeFormat be the this value.
2. Perform ? RequireInternalSlot(relativeTimeFormat, [[InitializedRelativeTimeFormat]]).
3. Let value be ? ToNumber(value).
4. Let unit be ? ToString(unit).
5. Return ? FormatRelativeTimeToParts(relativeTimeFormat, value, unit).
17.4.5 Intl.RelativeTimeFormat.prototype.resolvedOptions ()

This function provides access to the locale and options computed during initialization of the object.

1. Let relativeTimeFormat be the this value.
2. Perform ? RequireInternalSlot(relativeTimeFormat, [[InitializedRelativeTimeFormat]]).
3. Let options be ! OrdinaryObjectCreate(%Object.prototype%).
4. For each row of Table 14, except the header row, in table order, do
   a. Let p be the Property value of the current row.
   b. Let v be the value of relativeTimeFormat's internal slot whose name is the Internal Slot value of the current row.
   c. Assert: v is not undefined.
   d. Perform ! CreateDataPropertyOrThrow(options, p, v).
5. Return options.

Table 14: Resolved Options of RelativeTimeFormat Instances

<td>&quot;numberingSystem&quot;</td>
</tr>
</tbody>
</table>

17.5 Properties of Intl.RelativeTimeFormat Instances

Intl.RelativeTimeFormat instances are ordinary objects that inherit properties from %RelativeTimeFormat.prototype%.

Intl.RelativeTimeFormat instances have an [[InitializedRelativeTimeFormat]] internal slot.

Intl.RelativeTimeFormat instances also have several internal slots that are computed by the constructor:

- [[Locale]] is a String value with the language tag of the locale whose localization is used for formatting.
- [[DataLocale]] is a String value with the language tag of the nearest locale for which the implementation has data to perform the formatting operation. It will be a parent locale of [[Locale]].
- [[Style]] is one of the String values "long", "short", or "narrow", identifying the relative time format style used.
- [[Numeric]] is one of the String values "always" or "auto", identifying whether numerical descriptions are always used, or used only when no more specific version is available (e.g., "1 day ago" vs "yesterday").
- [[NumberFormat]] is an Intl.NumberFormat object used for formatting.
- [[NumberingSystem]] is a String value with the "type" given in Unicode Technical Standard 35 for the numbering system used for formatting.
- [[PluralRules]] is an Intl.PluralRules object used for formatting.

18 Locale Sensitive Functions of the ECMAScript Language Specification
The ECMAScript Language Specification, edition 10 or successor, describes several locale sensitive functions. An ECMAScript implementation that implements this Internationalization API Specification shall implement these functions as described here.

NOTE The Collator, NumberFormat, or DateTimeFormat objects created in the algorithms in this clause are only used within these algorithms. They are never directly accessed by ECMAScript code and need not actually exist within an implementation.

18.1 Properties of the String Prototype Object

18.1.1 String.prototype.localeCompare ( that [, locales [ , options ] ] )

This definition supersedes the definition provided in ES2021, 21.1.3.10.

When the `localeCompare` method is called with argument `that` and optional arguments `locales`, and `options`, the following steps are taken:

1. Let `O` be `RequireObjectCoercible(this value)`.  
2. Let `S` be ? `ToString(O)`.  
3. Let `thatValue` be ? `ToString(that)`.  
5. Return `CompareStrings(collator, S, thatValue)`.

The value of the "length" property of the `localeCompare` method is 1.

NOTE 1 The `localeCompare` method itself is not directly suitable as an argument to `Array.prototype.sort` because the latter requires a function of two arguments.

NOTE 2 The `localeCompare` function is intentionally generic; it does not require that its `this` value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

18.1.2 String.prototype.toLocaleLowerCase ( [ locales ] )

This definition supersedes the definition provided in ES2021, 21.1.3.23.

This function interprets a String value as a sequence of code points, as described in ES2021, 6.1.4. The following steps are taken:

1. Let `O` be `RequireObjectCoercible(this value)`.  
2. Let `S` be ? `ToString(O)`.  
3. Let `requestedLocales` be ? `CanonicalizeLocaleList(locales)`.  
4. If `requestedLocales` is not an empty List, then  
   a. Let `requestedLocale` be `requestedLocales[0]`.  
5. Else,  
   a. Let `requestedLocale` be `DefaultLocale()`.  
6. Let `noExtensionsLocale` be the String value that is `requestedLocale` with all Unicode locale extension sequences (6.2.1) removed.  
7. Let `availableLocales` be a List with language tags that includes the languages for which the Unicode Character Database contains language sensitive case mappings. Implementations may
add additional language tags if they support case mapping for additional locales.

8. Let \( \text{locale} \) be \( \text{BestAvailableLocale}(\text{availableLocales}, \text{noExtensionsLocale}) \).

9. If \( \text{locale} \) is undefined, let \( \text{locale} \) be "und".

10. Let \( \text{cpList} \) be a List containing in order the code points of \( S \) as defined in ES2021, 6.1.4, starting at the first element of \( S \).

11. Let \( \text{cuList} \) be a List where the elements are the result of a lower case transformation of the ordered code points in \( \text{cpList} \) according to the Unicode Default Case Conversion algorithm or an implementation-defined conversion algorithm. A conforming implementation's lower case transformation algorithm must always yield the same \( \text{cpList} \) given the same \( \text{cuList} \) and \( \text{locale} \).

12. Let \( L \) be a String whose elements are the UTF-16 Encoding (defined in ES2021, 6.1.4) of the code points of \( \text{cuList} \).

13. Return \( L \).

Lower case code point mappings may be derived according to a tailored version of the Default Case Conversion Algorithms of the Unicode Standard. Implementations may use locale specific tailoring defined in SpecialCasings.txt and/or CLDR and/or any other custom tailoring.

**NOTE 1** The case mapping of some code points may produce multiple code points. In this case the result String may not be the same length as the source String. Because both \( \text{toLocaleUpperCase} \) and \( \text{toLocaleLowerCase} \) have context-sensitive behaviour, the functions are not symmetrical. In other words, \( s.\text{toLocaleUpperCase}() . \text{toLocaleLowerCase}() \) is not necessarily equal to \( s.\text{toLocaleLowerCase}() \).

**NOTE 2** The \( \text{toLocaleLowerCase} \) function is intentionally generic; it does not require that its this value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

### 18.1.3 String.prototype.toLocaleUpperCase ([ `locales` ])

This function supersedes the definition provided in ES2021, 21.1.3.24.

This function interprets a String value as a sequence of code points, as described in ES2021, 6.1.4. This function behaves in exactly the same way as \( \text{String.prototype.toLocaleLowerCase} \), except that characters are mapped to their \( \text{uppercase} \) equivalents. A conforming implementation's upper case transformation algorithm must always yield the same result given the same sequence of code points and \( \text{locale} \).

**NOTE** The \( \text{toLocaleUpperCase} \) function is intentionally generic; it does not require that its this value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

### 18.2 Properties of the Number Prototype Object

The following definition(s) refer to the abstract operation \( \text{thisNumberValue} \) as defined in ES2021, 20.1.3.

#### 18.2.1 Number.prototype.toLocaleString ([ `locales` [ , `options` ] ])

This definition supersedes the definition provided in ES2021, 20.1.3.4.
When the `toLocaleString` method is called with optional arguments `locales` and `options`, the following steps are taken:

1. Let \( x \) be \( \text{thisNumberValue}(\text{this value}) \).
2. Let \( \text{numberFormat} \) be \( \text{Construct}(%\text{NumberFormat}%, \{\text{locales}, \text{options}\}) \).
3. Return \( \text{FormatNumeric}(\text{numberFormat}, x) \).

18.3 Properties of the BigInt Prototype Object

The following definition(s) refer to the abstract operation `thisBigIntValue` as defined in ES2021, 20.2.3.

18.3.1 BigInt.prototype.toLocaleString ( [ locales [, options ] ] )

This definition supersedes the definition provided in ES2021, 20.2.3.2.

When the `toLocaleString` method is called with optional arguments `locales` and `options`, the following steps are taken:

1. Let \( x \) be \( \text{thisBigIntValue}(\text{this value}) \).
2. Let \( \text{numberFormat} \) be \( \text{Construct}(%\text{NumberFormat}%, \{\text{locales}, \text{options}\}) \).
3. Return \( \text{FormatNumeric}(\text{numberFormat}, x) \).

18.4 Properties of the Date Prototype Object

The following definition(s) refer to the abstract operation `thisTimeValue` as defined in ES2021, 20.4.4.

18.4.1 Date.prototype.toLocaleString ( [ locales [, options ] ] )

This definition supersedes the definition provided in ES2021, 20.4.4.39.

When the `toLocaleString` method is called with optional arguments `locales` and `options`, the following steps are taken:

1. Let \( x \) be \( \text{thisTimeValue}(\text{this value}) \).
2. If \( x \) is \( \text{NaN} \), return "Invalid Date".
3. Let \( \text{options} \) be \( \text{ToDateTimeOptions}(\text{options}, \"any\", \"all\") \).
4. Let \( \text{dateFormat} \) be \( \text{Construct}(%\text{DateTimeFormat}%, \{\text{locales}, \text{options}\}) \).
5. Return \( \text{FormatDateTime}(\text{dateFormat}, x) \).

18.4.2 Date.prototype.toLocaleDateString ( [ locales [, options ] ] )

This definition supersedes the definition provided in ES2021, 20.4.4.38.

When the `toLocaleDateString` method is called with optional arguments `locales` and `options`, the following steps are taken:

1. Let \( x \) be \( \text{thisTimeValue}(\text{this value}) \).
2. If \( x \) is \( \text{NaN} \), return "Invalid Date".
3. Let \( \text{options} \) be \( \text{ToDateTimeOptions}(\text{options}, \"date\", \"date\") \).
4. Let \( \text{dateFormat} \) be \( \text{Construct}(%\text{DateTimeFormat}%, \{\text{locales}, \text{options}\}) \).
5. Return \( \text{FormatDateTime}(\text{dateFormat}, x) \).

18.4.3 Date.prototype.toLocaleTimeString ( [ locales [, options ] ] )

This definition supersedes the definition provided in ES2021, 20.4.4.39.

When the `toLocaleTimeString` method is called with optional arguments `locales` and `options`, the following steps are taken:

1. Let \( x \) be \( \text{thisTimeValue}(\text{this value}) \).
2. If \( x \) is \( \text{NaN} \), return "Invalid Date".
3. Let \( \text{options} \) be \( \text{ToDateTimeOptions}(\text{options}, \"date\", \"date\") \).
4. Let \( \text{dateFormat} \) be \( \text{Construct}(%\text{DateTimeFormat}%, \{\text{locales}, \text{options}\}) \).
5. Return \( \text{FormatDateTime}(\text{dateFormat}, x) \).
This definition supersedes the definition provided in ES2021, 20.4.4.40.

When the `toLocaleTimeString` method is called with optional arguments `locales` and `options`, the following steps are taken:

1. Let \( x \) be `? thisTimeValue(this value)`.
2. If \( x \) is `NaN`, return "Invalid Date".
3. Let `options` be `? ToDateTimeOptions(options, "time", "time")`.
4. Let `timeFormat` be `? Construct(%DateTimeFormat%, « locales, options »)`.
5. Return `? FormatDateTime(timeFormat, x)`.

18.5 Properties of the Array Prototype Object

18.5.1 `Array.prototype.toLocaleString ([ locales [, options ] ] )`

This definition supersedes the definition provided in ES2021, 22.1.3.29.

When the `toLocaleString` method is called with optional arguments `locales` and `options`, the following steps are taken:

1. Let `array` be `? ToObject(this value)`.
2. Let `len` be `? ToLength(? Get(array, "length"))`.
3. Let `separator` be the String value for the list-separator String appropriate for the host environment's current locale (this is derived in an implementation-defined way).
4. Let `R` be the empty String.
5. Let `k` be 0.
6. Repeat, while \( k < \text{len} \),
   a. If \( k > 0 \), then
      i. Set `R` to the string-concatenation of `R` and `separator`.
   b. Let `nextElement` be `? Get(array, ! ToString(k))`.
   c. If `nextElement` is not `undefined` or `null`, then
      ii. Set `R` to the string-concatenation of `R` and `S`.
   d. Increase `k` by 1.
7. Return `R`.

**NOTE 1** This algorithm’s steps mirror the steps taken in 22.1.3.29, with the exception that `Invoke(nextElement, "toLocaleString")` now takes `locales` and `options` as arguments.

**NOTE 2** The elements of the array are converted to Strings using their `toLocaleString` methods, and these Strings are then concatenated, separated by occurrences of a separator String that has been derived in an implementation-defined locale-specific way. The result of calling this function is intended to be analogous to the result of `toString`, except that the result of this function is intended to be locale-specific.

**NOTE 3** The `toLocaleString` function is intentionally generic; it does not require that its `this` value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method.
A Implementation Dependent Behaviour

The following aspects of the ECMAScript 2021 Internationalization API Specification are implementation dependent:

- In all functionality:
  - Additional values for some properties of `options` arguments (2)
  - The default locale (6.2.4)
  - The default time zone (6.4.3)
  - The set of available locales for each constructor (9.1)
  - The `BestFitMatcher` algorithm (9.2.4)
  - The `BestFitSupportedLocales` algorithm (9.2.9)

- In Collator:
  - Support for the Unicode extensions keys "kf", "kn" and the parallel options properties "caseFirst", "numeric" (10.1.1)
  - The set of supported "co" key values (collations) per locale beyond a default collation (10.2.3)
  - The set of supported "kf" key values (case order) per locale (10.2.3)
  - The set of supported "kn" key values (numeric collation) per locale (10.2.3)
  - The default search sensitivity per locale (10.2.3)
  - The sort order for each supported locale and options combination (10.3.3.1)

- In DateTimeFormat:
  - The `BestFitFormatMatcher` algorithm (11.1.1)
  - The set of supported "ca" key values (calendars) per locale (11.3.3)
  - The set of supported "nu" key values (numbering systems) per locale (11.3.3)
  - The default hourCycle setting per locale (11.3.3)
  - The set of supported date-time formats per locale beyond a core set, including the representations used for each component and the associated patterns (11.3.3)
  - Localized weekday names, era names, month names, day period names, am/pm indicators, and time zone names (11.1.9)
  - The calendric calculations used for calendars other than "gregory", and adjustments for local time zones and daylight saving time (11.1.9)

- In DisplayNames:
  - The localized names (12.3.3)

- In ListFormat:
  - The patterns used for formatting values (13.3.3)

- In Locale:
  - Support for the Unicode extensions keys "kf", "kn" and the parallel options properties "caseFirst", "numeric" (14.1.3)

- In NumberFormat:
  - The set of supported "nu" key values (numbering systems) per locale (15.3.3)
  - The patterns used for formatting values as decimal, percent, currency, or unit values per locale, with or without the sign, with or without accounting format for currencies, and in standard, compact, or scientific notation (15.1.8)
  - Localized representations of NaN and Infinity (15.1.8)
  - The implementation of numbering systems not listed in Table 10 (15.1.8)
  - Localized decimal and grouping separators (15.1.8)
  - Localized plus and minus signs (15.1.8)
  - Localized digit grouping schemata (15.1.8)
  - Localized magnitude thresholds for compact notation (15.1.8)
  - Localized symbols for compact and scientific notation (15.1.8)
  - Localized narrow, short, and long currency symbols and names (15.1.8)
  - Localized narrow, short, and long unit symbols (15.1.8)

- In PluralRules:
List of Strings representing the possible results of plural selection and their corresponding order per locale. (16.1.1)

- In RelativeTimeFormat:
  - The set of supported "nu" key values (numbering systems) per locale (17.3.3)
  - The patterns used for formatting values (17.3.3)

B Additions and Changes That Introduce Incompatibilities with Prior Editions

- 10.1, 15.2, 11.2 In ECMA-402, 1st Edition, constructors could be used to create Intl objects from arbitrary objects. This is no longer possible in 2nd Edition.
- 11.4.3 In ECMA-402, 1st Edition, the "length" property of the function object \( F \) was set to \(+0_{\text{𝔽}}\). In 2nd Edition, "length" is set to \( 1_{\text{𝔽}} \).
- 10.3.2 In ECMA-402, 7th Edition, the @@toStringTag property of Intl.Collator.prototype was set to "Object". In 8th Edition, @@toStringTag is set to "Intl.Collator".
- 11.4.2 In ECMA-402, 7th Edition, the @@toStringTag property of Intl.DateTimeFormat.prototype was set to "Object". In 8th Edition, @@toStringTag is set to "Intl.DateTimeFormat".
- 15.4.2 In ECMA-402, 7th Edition, the @@toStringTag property of Intl.NumberFormat.prototype was set to "Object". In 8th Edition, @@toStringTag is set to "Intl.NumberFormat".
- 16.4.2 In ECMA-402, 7th Edition, the @@toStringTag property of Intl.PluralRules.prototype was set to "Object". In 8th Edition, @@toStringTag is set to "Intl.PluralRules".
- 8.1.1 In ECMA-402, 7th Edition, the @@toStringTag property of Intl was not defined. In 8th Edition, @@toStringTag is set to "Intl".
- 15.2 In ECMA-402, 8th Edition, the NumberFormat constructor used to throw an error when style is "currency" and maximumFractionDigits was set to a value lower than the default fractional digits for that currency. This behaviour was corrected in the 9th edition, and it no longer throws an error.

C Colophon

This specification is authored on GitHub in a plaintext source format called Ecmarkup. Ecmarkup is an HTML and Markdown dialect that provides a framework and toolset for authoring ECMAScript specifications in plaintext and processing the specification into a full-featured HTML rendering that follows the editorial conventions for this document. Ecmarkup builds on and integrates a number of other formats and technologies including Grammarkdown for defining syntax and Ecmarkdown for authoring algorithm steps. PDF renderings of this specification are produced by printing the HTML rendering to a PDF.

Prior editions of this specification were authored using Word—the Ecmarkup source text that formed the basis of this edition was produced by converting the ECMAScript 2015 Word document to Ecmarkup using an automated conversion tool.
