Introduction

This specification’s source can be found at https://github.com/tc39/ecma402.

The ECMAScript 2023 Internationalization API Specification (ECMA-402 10th Edition), provides key language sensitive functionality as a complement to the ECMAScript 2023 Language Specification (ECMA-262 14th Edition or successor). Its functionality has been selected from that of well-established internationalization APIs such as those of the Internationalization Components for Unicode (ICU) library (https://unicode-org.github.io/icu-docs/), of the .NET framework, or of the Java platform.
The 1st Edition API was developed by an ad-hoc group established by Ecma TC39 in September 2010 based on a proposal by Nebojša Ćirić and Jungshik Shin.

The 2nd Edition API was adopted by the General Assembly of June 2015, as a complement to the ECMAScript 6th Edition.

The 3rd Edition API was the first edition released under Ecma TC39’s new yearly release cadence and open development process. A plain-text source document was built from the ECMA-402 source document to serve as the base for further development entirely on GitHub. Over the year of this standard’s development, dozens of pull requests and issues were filed representing several of bug fixes, editorial fixes and other improvements. Additionally, numerous software tools were developed to aid in this effort including Ecmarkup, Ecmarkdown, and Grammarkdown.

Dozens of individuals representing many organizations have made very significant contributions within Ecma TC39 to the development of this edition and to the prior editions. In addition, a vibrant community has emerged supporting TC39’s ECMAScript efforts. This community has reviewed numerous drafts, filed dozens of bug reports, performed implementation experiments, contributed test suites, and educated the world-wide developer community about ECMAScript Internationalization. Unfortunately, it is impossible to identify and acknowledge every person and organization who has contributed to this effort.

1 Scope

This Standard defines the application programming interface for ECMAScript objects that support programs that need to adapt to the linguistic and cultural conventions used by different human languages and countries.
2 Conformance

A conforming implementation of the ECMAScript 2022 Internationalization API Specification must conform to the ECMAScript 2022 Language Specification (ECMA-262 13th Edition, or successor), and must provide and support all the objects, properties, functions, and program semantics described in this specification.

A conforming implementation of the ECMAScript 2022 Internationalization API Specification is permitted to provide additional objects, properties, and functions beyond those described in this specification. In particular, a conforming implementation of the ECMAScript 2022 Internationalization API Specification is permitted to provide properties not described in this specification, and values for those properties, for objects that are described in this specification. A conforming implementation is not permitted to add optional arguments to the functions defined in this specification.

A conforming implementation is permitted to accept additional values, and then have implementation-defined behaviour instead of throwing a `RangeError`, for the following properties of `options` arguments:

- The `options` property "localeMatcher" in all constructors and `supportedLocalesOf` methods.
- The `options` properties "usage" and "sensitivity" in the Collator constructor.
- The `options` properties "style", "currencyDisplay", "notation", "compactDisplay", "signDisplay", "currencySign", and "unitDisplay" in the NumberFormat constructor.
- The `options` properties "minimumIntegerDigits", "minimumFractionDigits", "maximumFractionDigits", "minimumSignificantDigits", and "maximumSignificantDigits" in the NumberFormat constructor, provided that the additional values are interpreted as `integer` values higher than the specified limits.
- The `options` properties listed in Table 6 in the DateTimeFormat constructor.
- The `options` property "formatMatcher" in the DateTimeFormat constructor.
- The `options` properties "minimumIntegerDigits", "minimumFractionDigits", "maximumFractionDigits", and "minimumSignificantDigits" in the PluralRules constructor, provided that the additional values are interpreted as `integer` values higher than the specified limits.
- The `options` property "type" in the PluralRules constructor.
- The `options` property "style" and "numeric" in the RelativeTimeFormat constructor.
- The `options` property "style" and "type" in the DisplayNames constructor.

3 Normative References

The following referenced documents are required for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

https://www.ecma-international.org/publications/standards/Ecma-262.htm

NOTE

Throughout this document, the phrase “es2022, x” (where x is a sequence of numbers separated by periods) may be used as shorthand for "ECMAScript 2022 Language Specification (ECMA-262 13th Edition, sub clause x)".

- ISO/IEC 10646:2014: Information Technology – Universal Multiple-Octet Coded Character Set (UCS) plus Amendment 1:2015 and Amendment 2, plus additional amendments and corrigenda, or successor
4 Overview

This section contains a non-normative overview of the ECMAScript 2022 Internationalization API Specification.

4.1 Internationalization, Localization, and Globalization

Internationalization of software means designing it such that it supports or can be easily adapted to support the needs of users speaking different languages and having different cultural expectations, and enables worldwide communication between them. Localization then is the actual adaptation to a specific language and culture. Globalization of software is commonly understood to be the combination of internationalization and localization. Globalization starts at the lowest level by using a text representation that supports all languages in the world, and using standard identifiers to identify languages, countries, time zones, and other relevant parameters. It continues with using a user interface language and data presentation that the user understands, and finally often requires product-specific adaptations to the user’s language, culture, and environment.

The ECMAScript 2022 Language Specification lays the foundation by using Unicode for text representation and by providing a few language-sensitive functions, but gives applications little control over the behaviour of these functions. The ECMAScript 2022 Internationalization API Specification builds on this by providing a set of customizable language-sensitive functionality. The API is useful even for applications that themselves are not internationalized, as even applications targeting only one language and one region need to properly support that one language and region. However, the API also enables applications that support multiple languages and regions, even concurrently, as may be needed in server environments.

4.2 API Overview

The ECMAScript 2022 Internationalization API Specification is designed to complement the ECMAScript 2022 Language Specification by providing key language-sensitive functionality. The API can be added to an implementation of the ECMAScript 2022 Language Specification (ECMA-262 13th Edition, or successor).

The ECMAScript 2022 Internationalization API Specification provides several key pieces of language-sensitive functionality that are required in most applications: String comparison (collation), number formatting, date and time formatting, relative time formatting, display names, list formatting, locale selection and operation, pluralization rules, case conversion, and text segmentation. While the ECMAScript 2022 Language Specification...
provides functions for this basic functionality (on Array.prototype: `toLocaleString`; on String.prototype: `localeCompare`, `toLocaleLowerCase`, `toLocaleUpperCase`; on Number.prototype: `toLocaleString`; on Date.prototype: `toLocaleString`, `toLocaleDateString`, and `toLocaleTimeString`), their actual behaviour is left largely implementation-defined. The ECMAScript 2022 Internationalization API Specification provides additional functionality, control over the language and over details of the behaviour to be used, and a more complete specification of required functionality.

Applications can use the API in two ways:

1. Directly, by using a service constructor to construct an object, specifying a list of preferred languages and options to configure its behaviour. The object provides a main function (compare, select, format, etc.), which can be called repeatedly. It also provides a `resolvedOptions` function, which the application can use to find out the exact configuration of the object.
2. Indirectly, by using the functions of the ECMAScript 2022 Language Specification mentioned above. The collation and formatting functions are respecified in this specification to accept the same arguments as the Collator, NumberFormat, and DateTimeFormat constructors and produce the same results as their compare or format methods. The case conversion functions are respecified to accept a list of preferred languages.

The Intl object is used to package all functionality defined in the ECMAScript 2022 Internationalization API Specification to avoid name collisions.

**NOTE** While the API includes a variety of formatters, it does not provide any parsing facilities. This is intentional, has been discussed extensively, and concluded after weighing in all the benefits and drawbacks of including said functionality. See the discussion on the issue tracker.

### 4.3 API Conventions

Every Intl constructor should behave as if defined by a class, throwing a TypeError exception when called as a function (without NewTarget). For backwards compatibility with past editions, this does not apply to `%Collator%`, `%DateTimeFormat%`, or `%NumberFormat%`, each of which construct and return a new object when called as a function.

**NOTE** In ECMA 402 v1, Intl constructors supported a mode of operation where calling them with an existing object as a receiver would add relevant internal slots to the receiver, effectively transforming it into an instance of the class. In ECMA 402 v2, this capability was removed, to avoid adding internal slots to existing objects. In ECMA 402 v3, the capability was re-added as "normative optional" in a mode which chains the underlying Intl instance on any object, when the constructor is called. See Issue 57 for details.

### 4.4 Implementation Dependencies

Due to the nature of internationalization, the API specification has to leave several details implementation dependent:

- *The set of locales that an implementation supports with adequate localizations:* Linguists estimate the number of human languages to around 6000, and the more widely spoken ones have variations based on regions or...
other parameters. Even large locale data collections, such as the Common Locale Data Repository, cover only a subset of this large set. Implementations targeting resource-constrained devices may have to further reduce the subset.

- **The exact form of localizations such as format patterns**: In many cases locale-dependent conventions are not standardized, so different forms may exist side by side, or they vary over time. Different internationalization libraries may have implemented different forms, without any of them being actually wrong. In order to allow this API to be implemented on top of existing libraries, such variations have to be permitted.

- **Subsets of Unicode**: Some operations, such as collation, operate on strings that can include characters from the entire Unicode character set. However, both the Unicode Standard and the ECMAScript standard allow implementations to limit their functionality to subsets of the Unicode character set. In addition, locale conventions typically don’t specify the desired behaviour for the entire Unicode character set, but only for those characters that are relevant for the locale. While the Unicode Collation Algorithm combines a default collation order for the entire Unicode character set with the ability to tailor for local conventions, subsets and tailorings still result in differences in behaviour.

### 4.4.1 Compatibility across implementations

ECMA 402 describes the schema of the data used by its functions. The data contained inside is implementation-dependent, and expected to change over time and vary between implementations. The variation is visible by programmers, and it is possible to construct programs which will depend on a particular output. However, this specification attempts to describe reasonable constraints which will allow well-written programs to function across implementations. Implementations are encouraged to continue their efforts to harmonize linguistic data.

### 5 Notational Conventions

This standard uses a subset of the notational conventions of the ECMAScript 2022 Language Specification (ECMA-262 13th Edition), as es2022:

- **Object Internal Methods and Internal Slots**, as described in es2022, 6.1.7.2.
- **Algorithm conventions**, as described in es2022, 5.2, and the use of **abstract operations**, as described in es2022, 7.1, 7.2, 7.3, 7.4.
- **Internal Slots**, as described in es2022, 9.1.
- **The List and Record Specification Type**, as described in es2022, 6.2.1.

#### NOTE

As described in the ECMAScript Language Specification, algorithms are used to precisely specify the required semantics of ECMAScript constructs, but are not intended to imply the use of any specific implementation technique. Internal slots are used to define the semantics of object values, but are not part of the API. They are defined purely for expository purposes. An implementation of the API must behave as if it produced and operated upon internal slots in the manner described here.

As an extension to the Record Specification Type, the notation “[\[<name>\]]” denotes a field whose name is given by the variable name, which must have a String value. For example, if a variable s has the value "a", then [[<s>]] denotes the field [[a]].
This specification uses blocks demarcated as Normative Optional to denote the sense of Annex B in ECMA 262. That is, normative optional sections are required when the ECMAScript host is a web browser. The content of the section is normative but optional if the ECMAScript host is not a web browser.

5.1 Well-Known Intrinsic Objects

The following table extends the Well-Known Intrinsic Objects table defined in es2022, 6.1.7.4.

<table>
<thead>
<tr>
<th>Intrinsic Name</th>
<th>Global Name</th>
<th>ECMAScript Language Association</th>
</tr>
</thead>
<tbody>
<tr>
<td>%Collator%</td>
<td>Intl.Collator</td>
<td>The Intl.Collator constructor (10.1)</td>

</table>

6 Identification of Locales, Currencies, Time Zones, and Measurement Units

This clause describes the String values used in the ECMAScript 2022 Internationalization API Specification to identify locales, currencies, time zones, and measurement units.

6.1 Case Sensitivity and Case Mapping

The String values used to identify locales, currencies, scripts, and time zones are interpreted in an ASCII-case-insensitive manner, treating the code units 0x0041 through 0x005A (corresponding to Unicode characters LATIN CAPITAL LETTER A through LATIN CAPITAL LETTER Z) as equivalent to the corresponding code units 0x0061 through 0x007A (corresponding to Unicode characters LATIN SMALL LETTER A through LATIN SMALL LETTER Z), both inclusive. No other case folding equivalences are applied.

NOTE For example, "ß" (U+00DF) must not match or be mapped to "SS" (U+0053, U+0053). "ı" (U+0131) must not match or be mapped to "T" (U+0049).
The ASCII-uppercase of a String value \( S \) is the String value derived from \( S \) by replacing each occurrence of an ASCII lowercase letter code unit (0x0061 through 0x007A, inclusive) with the corresponding ASCII uppercase letter code unit (0x0041 through 0x005A, inclusive) while preserving all other code units.

The ASCII-lowercase of a String value \( S \) is the String value derived from \( S \) by replacing each occurrence of an ASCII uppercase letter code unit (0x0041 through 0x005A, inclusive) with the corresponding ASCII lowercase letter code unit (0x0061 through 0x007A, inclusive) while preserving all other code units.

A String value \( A \) is an ASCII-case-insensitive match for String value \( B \) if the ASCII-uppercase of \( A \) is exactly the same sequence of code units as the ASCII-uppercase of \( B \). A sequence of Unicode code points \( A \) is an ASCII-case-insensitive match for \( B \) if \( B \) is an ASCII-case-insensitive match for \( ! \) \text{CodePointsToString}(A).

### 6.2 Language Tags

The ECMAScript 2022 Internationalization API Specification identifies locales using Unicode BCP 47 locale identifiers as defined by Unicode Technical Standard #35 LDML § 3 Unicode Language and Locale Identifiers, which may include extensions such as the Unicode BCP 47 U Extension. Their canonical form is specified in Unicode Technical Standard #35 LDML § 3.2.1 Canonical Unicode Locale Identifiers.

Unicode BCP 47 locale identifiers are structurally valid when they match those syntactical formatting criteria of Unicode Technical Standard 35, section 3.2, but it is not required to validate them according to the Unicode validation data. All structurally valid language tags are valid for use with the APIs defined by this standard. However, the set of locales and thus language tags that an implementation supports with adequate localizations is implementation dependent. Intl constructors map the language tags used in requests to locales supported by their respective implementations.

#### 6.2.1 Unicode Locale Extension Sequences

This standard uses the term "Unicode locale extension sequence" - as described in \texttt{unicode_locale_extensions} in UTS 35 Unicode Locale Identifier, section 3.2 - for any substring of a language tag that is not part of a private use subtag sequence, starts with a separator ",-" and the singleton "u", and includes the maximum sequence of following non-singleton subtags and their preceding ",-" separators.

#### 6.2.2 IsStructurallyValidLanguageTag ( \texttt{locale} )

The IsStructurallyValidLanguageTag abstract operation determines whether the \texttt{locale} argument (which must be a String value) is a language tag recognized by this specification. (It does not consider whether the language tag conveys any meaningful semantics, differentiate between aliased subtags and their preferred replacement subtags, or require canonical casing or subtag ordering.)

IsStructurallyValidLanguageTag returns \texttt{true} if all of the following conditions hold, \texttt{false} otherwise:

- \texttt{locale} can be generated from the EBNF grammar for \texttt{unicode.locale.id} in Unicode Technical Standard #35 LDML § 3.2 Unicode Locale Identifier;
- \texttt{locale} does not use any of the backwards compatibility syntax described in Unicode Technical Standard #35 LDML § 3.3 BCP 47 Conformance;
- the \texttt{unicode.language.id} within \texttt{locale} contains no duplicate \texttt{unicode.variant.subtag} subtags; and
if `locale` contains an `extensions*` component, that component
- does not contain any `other_extensions` components with duplicate `[alphanum-[tTuUxX]]`
  subtags,
- contains at most one `unicode_locale_extensions` component,
- contains at most one `transformed_extensions` component, and
- if a `transformed_extensions` component that contains a `tlang` component is present, then
  - the `tlang` component contains no duplicate `unicode_variant_subtag` subtags.

When evaluating each condition, terminal value characters in the grammar are interpreted as the corresponding Basic Latin code points. Two subtags are duplicates if one is an ASCII-case-insensitive match for the other.

### NOTE
Every string for which this function returns `true` is both a "Unicode BCP 47 locale identifier", consistent with Unicode Technical Standard #35 LDML § 3.2 Unicode Locale Identifier and Unicode Technical Standard #35 LDML § 3.3 BCP 47 Conformance, and a valid BCP 47 language tag.

#### 6.2.3 CanonicalizeUnicodeLocaleId ( `locale` )

The CanonicalizeUnicodeLocaleId abstract operation returns the canonical and case-regularized form of the `locale` argument (which must be a String value for which `IsStructurallyValidLanguageTag(locale)` equals `true`). The following steps are taken:

1. Let `localeId` be the string `locale` after performing the algorithm to transform it to canonical syntax per Unicode Technical Standard #35 LDML § 3.2.1 Canonical Unicode Locale Identifiers. (The result is a Unicode BCP 47 locale identifier, in canonical syntax but not necessarily in canonical form.)
2. Let `localeId` be the string `localeId` after performing the algorithm to transform it to canonical form. (The result is a Unicode BCP 47 locale identifier, in both canonical syntax and canonical form.)
3. If `localeId` contains a substring `extension` that is a Unicode locale extension sequence, then
   a. Let `components` be ![UnicodeExtensionComponents(extension)].
   b. Let `attributes` be `components`.[[Attributes]].
   c. Let `keywords` be `components`.[[Keywords]].
   d. Let `newExtension` be "u".
   e. For each element `attr` of `attributes`, do
      i. Append ":" to `newExtension`.
      ii. Append `attr` to `newExtension`.
   f. For each Record `{ [[Key]], [[Value]] } `keyword` in `keywords`, do
      i. Append ":" to `newExtension`.
      ii. Append `keyword`.[[Key]] to `newExtension`.
      iii. If `keyword`.[[Value]] is not the empty String, then
           1. Append ":" to `newExtension`.
           2. Append `keyword`.[[Value]] to `newExtension`.
   g. Assert: `newExtension` is not equal to "u".
   h. Let `localeId` be `localeId` with the substring corresponding to `extension` replaced by the string `newExtension`.
4. Return `localeId`.

### NOTE
The third step of this algorithm ensures that a Unicode locale extension sequence in the returned language tag contains:
only the first instance of any attribute duplicated in the input, and
only the first keyword for a given key in the input.

6.2.4 DefaultLocale ()

The DefaultLocale abstract operation returns a String value representing the structurally valid (6.2.2) and canonicalized (6.2.3) Unicode BCP 47 locale identifier for the host environment's current locale.

6.3 Currency Codes

The ECMAScript 2022 Internationalization API Specification identifies currencies using 3-letter currency codes as defined by ISO 4217. Their canonical form is uppercase.

All well-formed 3-letter ISO 4217 currency codes are allowed. However, the set of combinations of currency code and language tag for which localized currency symbols are available is implementation dependent. Where a localized currency symbol is not available, the ISO 4217 currency code is used for formatting.

6.3.1 IsWellFormedCurrencyCode (currency)

The IsWellFormedCurrencyCode abstract operation verifies that the currency argument (which must be a String value) represents a well-formed 3-letter ISO currency code. The following steps are taken:

1. If the length of normalized is not 3, return false.
2. Let normalized be the ASCII-uppercase of currency.
3. If normalized contains any code unit outside of 0x0041 through 0x005A (corresponding to Unicode characters LATIN CAPITAL LETTER A through LATIN CAPITAL LETTER Z), return false.
4. Return true.

6.4 Time Zone Names

The ECMAScript 2022 Internationalization API Specification identifies time zones using the Zone and Link names of the IANA Time Zone Database. Their canonical form is the corresponding Zone name in the casing used in the IANA Time Zone Database except as specifically overridden by CanonicalizeTimeZoneName.

A conforming implementation must recognize "UTC" and all other Zone and Link names (and only such names), and use best available current and historical information about their offsets from UTC and their daylight saving time rules in calculations. However, the set of combinations of time zone name and language tag for which localized time zone names are available is implementation dependent.

6.4.1 IsValidTimeZoneName (timeZone)

The abstract operation IsValidTimeZoneName takes argument timeZone, a String value, and verifies that it represents a valid Zone or Link name of the IANA Time Zone Database.

1. If one of the Zone or Link names of the IANA Time Zone Database is an ASCII-case-insensitive match of timeZone, return true.
2. If `timeZone` is an ASCII-case-insensitive match of "UTC", return `true`.
3. Return `false`.

NOTE Any value returned from `DefaultTimeZone` must be recognized as valid.

### 6.4.2 CanonicalizeTimeZoneName ( `timeZone` )

The abstract operation `CanonicalizeTimeZoneName` takes argument `timeZone` (a String value that is a valid time zone name as verified by `IsValidTimeZoneName`). It returns the canonical and case-regularized form of `timeZone`. It performs the following steps when called:

1. Let `ianaTimeZone` be the String value of the Zone or Link name of the IANA Time Zone Database that is an ASCII-case-insensitive match of `timeZone`.
2. If `ianaTimeZone` is a Link name, let `ianaTimeZone` be the String value of the corresponding Zone name as specified in the file backward of the IANA Time Zone Database.
3. If `ianaTimeZone` is "Etc/UTC" or "Etc/GMT", return "UTC".
4. Return `ianaTimeZone`.

### 6.4.3 DefaultTimeZone ( )

The `DefaultTimeZone` abstract operation returns a String value representing the valid (6.4.1) and canonicalized (6.4.2) time zone name for the host environment’s current time zone.

### 6.5 Measurement Unit Identifiers

The ECMAScript 2022 Internationalization API Specification identifies measurement units using a core unit identifier (or equivalently core unit ID) as defined by Unicode Technical Standard #35, Part 2, Section 6.2. Their canonical form is a string containing only Unicode Basic Latin lowercase letters (U+0061 LATIN SMALL LETTER A through U+007A LATIN SMALL LETTER Z) with zero or more medial hyphens (U+002D HYPHEN-MINUS).

Only a limited set of core unit identifiers are sanctioned. Attempting to use an unsanctioned core unit identifier results in a RangeError.

#### 6.5.1 IsWellFormedUnitIdentifier ( `unitIdentifier` )

The `IsWellFormedUnitIdentifier` abstract operation verifies that the `unitIdentifier` argument (which must be a String value) represents a well-formed UTS #35 core unit identifier that is either a sanctioned single unit or a complex unit formed by division of two sanctioned single units. The following steps are taken:

1. If `IsSanctionedSingleUnitIdentifier(unitIdentifier)` is `true`, then
   a. Return `true`.
2. Let `i` be `StringIndexOf(unitIdentifier, "-per-", 0).
3. If `i` is -1 or `StringIndexOf(unitIdentifier, "-per-", `i` + 1)` is not -1, then
   a. Return `false`.
4. Assert: The five-character substring "-per-" occurs exactly once in `unitIdentifier`, at index `i`.
5. Let `numerator` be the substring of `unitIdentifier` from 0 to `i`. 
6. Let denominator be the substring of unitIdentifier from \( i + 5 \).
7. If \( \text{IsSanctionedSingleUnitIdentifier}(\text{numerator}) \) and \( \text{IsSanctionedSingleUnitIdentifier}(\text{denominator}) \) are both true, then
   a. Return true.
8. Return false.

### 6.5.2 IsSanctionedSingleUnitIdentifier (unitIdentifier)

The IsSanctionedSingleUnitIdentifier abstract operation verifies that the unitIdentifier argument (which must be a String value) is among the single unit identifiers sanctioned in the current version of the ECMAScript Internationalization API Specification, which are a subset of the Common Locale Data Repository release 38 unit validity data; the list may grow over time. As discussed in UTS #35, a single unit identifier is a core unit identifier that is not composed of multiplication or division of other unit identifiers. The following steps are taken:

1. If unitIdentifier is listed in Table 2 below, return true.
2. Else, return false.

### Table 2: Single units sanctioned for use in ECMAScript

7 Requirements for Standard Built-in ECMAScript Objects
8 The Intl Object

The Intl object is the `%Intl%` intrinsic object and the initial value of the "Intl" property of the global object. The Intl object is a single ordinary object.

The value of the [[Prototype]] internal slot of the Intl object is the intrinsic object `%Object.prototype%`.

The Intl object is not a function object. It does not have a [[Construct]] internal method; it is not possible to use the Intl object as a constructor with the new operator. The Intl object does not have a [[Call]] internal method; it is not possible to invoke the Intl object as a function.

The Intl object has an internal slot, [[FallbackSymbol]], which is a new `%Symbol%` in the current realm with the [[Description]] "IntlLegacyConstructedSymbol".

8.1 Value Properties of the Intl Object

8.1.1 Intl[ @@toStringTag ]

The initial value of the @@toStringTag property is the String value "Intl".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

8.2 Constructor Properties of the Intl Object

With the exception of Intl.Locale, each of the following constructors is a service constructor that creates objects providing locale-sensitive services.

8.2.1 Intl.Collator ( . . . )

See 10.

8.2.2 Intl.DateTimeFormat ( . . . )

See 11.

8.2.3 Intl.DisplayNames ( . . . )

See 12.

8.2.4 Intl.ListFormat ( . . . )
When the `getCanonicalLocales` method is called with argument `locales`, the following steps are taken:

1. Let `ll` be `CanonicalizeLocaleList(locales)`. 
2. Return `CreateArrayFromList(ll)`. 

9 Locale and Parameter Negotiation

Service constructors use a common pattern to negotiate the requests represented by their `locales` and `options` arguments against the actual capabilities of their implementations. That common behaviour is explained here in terms of internal slots describing the capabilities and abstract operations using these internal slots.

9.1 Internal slots of Service Constructors

Each service constructor has the following internal slots:

- `[[AvailableLocales]]` is a List that contains structurally valid (6.2.2) and canonicalized (6.2.3) Unicode BCP 47 locale identifiers identifying the locales for which the implementation provides the functionality of the constructed objects. Language tags on the list must not have a Unicode locale extension sequence. The list
must include the value returned by the `DefaultLocale` abstract operation (6.2.4), and must not include duplicates. Implementations must include in `[[AvailableLocales]]` locales that can serve as fallbacks in the algorithm used to resolve locales (see 9.2.7). For example, implementations that provide a "de-DE" locale must include a "de" locale that can serve as a fallback for requests such as "de-AT" and "de-CH". For locales that include a script subtag in addition to language and region, the corresponding locale without a script subtag must also be supported; that is, if an implementation recognizes "zh-Hant-TW", it is also expected to recognize "zh-TW". The ordering of the locales within `[[AvailableLocales]]` is irrelevant.

- `[[RelevantExtensionKeys]]` is a List of keys of the language tag extensions defined in Unicode Technical Standard 35 that are relevant for the functionality of the constructed objects.
- `[[SortLocaleData]]` and `[[SearchLocaleData]]` (for Intl.Collator) and `[[LocaleData]]` (for every other service constructor) are records that have fields for each locale contained in `[[AvailableLocales]]`. The value of each of these fields must be a record that has fields for each key contained in `[[RelevantExtensionKeys]]`. The value of each of these fields must be a non-empty list of those values defined in Unicode Technical Standard 35 for the given key that are supported by the implementation for the given locale, with the first element providing the default value.

**NOTE** For example, an implementation of DateTimeFormat might include the language tag "th" in its `[[AvailableLocales]]` internal slot, and must (according to 11.2.3) include the key "ca" in its `[[RelevantExtensionKeys]]` internal slot. For Thai, the "buddhist" calendar is usually the default, but an implementation might also support the calendars "gregory", "chinese", and "islamic" for the locale "th". The `[[LocaleData]]` internal slot would therefore at least include `{ [[th]]: { [[ca]]: « "buddhist", "gregory", "chinese", "islamic" » }}`.

### 9.2 Abstract Operations

Where the following abstract operations take an `availableLocales` argument, it must be an `[[AvailableLocales]] List` as specified in 9.1.

#### 9.2.1 CanonicalizeLocaleList ( `locales` )

The abstract operation CanonicalizeLocaleList takes the following steps:

1. If `locales` is undefined, then
   a. Return a new empty List.
2. Let `seen` be a new empty List.
3. If `Type(locales)` is String or `Type(locales)` is Object and `locales` has an `[[InitializedLocale]]` internal slot, then
   a. Let `O` be `! CreateArrayFromList(« locales »)`.
4. Else,
   a. Let `O` be `? ToObject(locales)`.
5. Let `len` be `? ToLength(? Get(O, "length"))`.
6. Let `k` be 0.
7. Repeat, while `k < len`,
   a. Let `Pk` be `ToString(k)`.
   b. Let `kPresent` be `? HasProperty(O, Pk)`.
   c. If `kPresent` is true, then
      i. Let `kValue` be `? Get(O, Pk)`.
      ii. If `Type(kValue)` is not String or Object, throw a `TypeError` exception.
iii. If \( Type(kValue) \) is Object and \( kValue \) has an \([\text{InitializedLocale}]\) internal slot, then
   1. Let \( tag = kValue.[[Locale]] \).

iv. Else,
   1. Let \( tag = ? \text{ToString}(kValue) \).

v. If \( \text{IsStructurallyValidLanguageTag}(tag) \) is \text{false}, throw a \text{RangeError} exception.

vi. Let \( \text{canonicalizedTag} = ! \text{CanonicalizeUnicodeLocaleId}(tag) \).

vii. If \( \text{canonicalizedTag} \) is not an element of \( \text{seen} \), append \( \text{canonicalizedTag} \) as the last element of \( \text{seen} \).

d. Increase \( k \) by 1.

8. Return \( \text{seen} \).

**NOTE 1**
Non-normative summary: The abstract operation interprets the \( \text{locales} \) argument as an array and copies its elements into a \text{List}, validating the elements as structurally valid language tags and canonicalizing them, and omitting duplicates.

**NOTE 2**
Requiring \( kValue \) to be a String or Object means that the \text{Number} value \( \text{NaN} \) will not be interpreted as the language tag "nan", which stands for Min Nan Chinese.

### 9.2.2 BestAvailableLocale ( \( \text{availableLocales, locale} \) )

The BestAvailableLocale abstract operation compares the provided argument \( \text{locale} \), which must be a String value with a structurally valid and canonicalized Unicode BCP 47 locale identifier, against the locales in \( \text{availableLocales} \) and returns either the longest non-empty prefix of \( \text{locale} \) that is an element of \( \text{availableLocales} \), or \text{undefined} if there is no such element. It uses the fallback mechanism of RFC 4647, section 3.4. The following steps are taken:

1. Let \( \text{candidate} = \text{locale} \).

2. Repeat,
   a. If \( \text{availableLocales} \) contains an element equal to \( \text{candidate} \), return \( \text{candidate} \).
   
   b. Let \( \text{pos} \) be the character index of the last occurrence of "-" (U+002D) within \( \text{candidate} \). If that character does not occur, return \text{undefined}.

   c. If \( \text{pos} ≥ 2 \) and the character "-" occurs at index \( \text{pos}-2 \) of \( \text{candidate} \), decrease \( \text{pos} \) by 2.

   d. Let \( \text{candidate} \) be the substring of \( \text{candidate} \) from position 0, inclusive, to position \( \text{pos} \), exclusive.

### 9.2.3 LookupMatcher ( \( \text{availableLocales, requestedLocales} \) )

The LookupMatcher abstract operation compares \( \text{requestedLocales} \), which must be a \text{List} as returned by \text{CanonicalizeLocaleList}, against the locales in \( \text{availableLocales} \) and determines the best available language to meet the request. The following steps are taken:

1. Let \( \text{result} \) be a new \text{Record}.

2. For each element \( \text{locale} \) of \( \text{requestedLocales} \), do
   a. Let \( \text{noExtensionsLocale} \) be the String value that is \( \text{locale} \) with any Unicode locale extension sequences removed.

   b. Let \( \text{availableLocale} \) be \( ! \text{BestAvailableLocale}(\text{availableLocales}, \text{noExtensionsLocale}) \).

   c. If \( \text{availableLocale} \) is not \text{undefined}, then
      i. Set \( \text{result}[[\text{locale}]] \) to \( \text{availableLocale} \).

      ii. If \( \text{locale} \) and \( \text{noExtensionsLocale} \) are not the same String value, then
1. Let $extension$ be the String value consisting of the substring of the Unicode locale extension sequence within $locale$.

2. Set $result.[extension]$ to $extension$.

iii. Return $result$.

3. Let $defLocale$ be DefaultLocale().

4. Set $result.[locale]$ to $defLocale$.

5. Return $result$.

NOTE

The algorithm is based on the Lookup algorithm described in RFC 4647 section 3.4, but options specified through Unicode locale extension sequences are ignored in the lookup. Information about such subsequences is returned separately. The abstract operation returns a record with a $[locale]$ field, whose value is the language tag of the selected locale, which must be an element of $availableLocales$. If the language tag of the request locale that led to the selected locale contained a Unicode locale extension sequence, then the returned record also contains an $[extension]$ field whose value is the substring of the Unicode locale extension sequence within the request locale language tag.

### 9.2.4 BestFitMatcher ( $availableLocales$, $requestedLocales$ )

The BestFitMatcher abstract operation compares $requestedLocales$, which must be a List as returned by CanonicalizeLocaleList, against the locales in $availableLocales$ and determines the best available language to meet the request. The algorithm is implementation dependent, but should produce results that a typical user of the requested locales would perceive as at least as good as those produced by the LookupMatcher abstract operation. Options specified through Unicode locale extension sequences must be ignored by the algorithm. Information about such subsequences is returned separately. The abstract operation returns a record with a $[locale]$ field, whose value is the language tag of the selected locale, which must be an element of $availableLocales$. If the language tag of the request locale that led to the selected locale contained a Unicode locale extension sequence, then the returned record also contains an $[extension]$ field whose value is the substring of the Unicode locale extension sequence within the request locale language tag.

### 9.2.5 UnicodeExtensionComponents ( $extension$ )

The UnicodeExtensionComponents abstract operation returns the attributes and keywords from $extension$, which must be a String value whose contents are a Unicode locale extension sequence. If an attribute or a keyword occurs multiple times in $extension$, only the first occurrence is returned. The following steps are taken:

1. Let $attributes$ be a new empty List.
2. Let $keywords$ be a new empty List.
3. Let $keyword$ be undefined.
4. Let $size$ be the length of $extension$.
5. Let $k$ be 3.
6. Repeat, while $k < size$,
   a. Let $e$ be ! StringIndexOf($extension$, ",", $k$).
   b. If $e = -1$, let $len$ be $size - k$; else let $len$ be $e - k$.
   c. Let $subtag$ be the String value equal to the substring of $extension$ consisting of the code units at indices $k$ (inclusive) through $k + len$ (exclusive).
   d. If $keyword$ is undefined and $len \neq 2$, then
      i. If $subtag$ is not an element of $attributes$, then
1. Append `subtag` to `attributes`.

e. Else if `len` = 2, then
   i. If `keyword` is not `undefined` and `keywords` does not contain an element whose `[[Key]]` is the same as `keyword`.[[Key]], then
      1. Append `keyword` to `keywords`.
   ii. Set `keyword` to the Record { `[[Key]]`: `subtag`, `[[Value]]`: "" }.

f. Else,
   i. If `keyword`.[[Value]] is the empty String, then
      1. Set `keyword`.[[Value]] to `subtag`.
   ii. Else,
      1. Set `keyword`.[[Value]] to the string-concatenation of `keyword`.[[Value]], "," and `subtag`.

g. Let `k` be `k + len + 1`.

7. If `keyword` is not `undefined` and `keywords` does not contain an element whose `[[Key]]` is the same as `keyword`.[[Key]], then
   a. Append `keyword` to `keywords`.
8. Return the Record { `[[Attributes]]`: `attributes`, `[[Keywords]]`: `keywords` }.

9.2.6 InsertUnicodeExtensionAndCanonicalize ( `locale`, `extension` )

The `InsertUnicodeExtensionAndCanonicalize` abstract operation inserts `extension`, which must be a Unicode locale extension sequence, into `locale`, which must be a String value with a structurally valid and canonicalized Unicode BCP 47 locale identifier. The following steps are taken:

The following algorithm refers to UTS 35's Unicode Language and Locale Identifiers grammar.

1. Assert: `locale` does not contain a substring that is a Unicode locale extension sequence.
2. Assert: `extension` is a Unicode locale extension sequence.
3. Assert: `tag` matches the `unicode_locale_id` production.
4. Let `privateIndex` be `~StringIndexOf(~locale,~-x-,0)`.
5. If `privateIndex` = -1, then
   a. Let `locale` be the string-concatenation of `locale` and `extension`.
6. Else,
   a. Let `preExtension` be the substring of `locale` from position 0, inclusive, to position `privateIndex`, exclusive.
   b. Let `postExtension` be the substring of `locale` from position `privateIndex` to the end of the string.
   c. Let `locale` be the string-concatenation of `preExtension`, `extension`, and `postExtension`.

7. Assert: ! IsStructurallyValidLanguageTag(`locale`) is true.
8. Return ! CanonicalizeUnicodeLocaleId(`locale`).

9.2.7 ResolveLocale ( `availableLocales`, `requestedLocales`, `options`, `relevantExtensionKeys`, `localeData` )

The `ResolveLocale` abstract operation compares a BCP 47 language priority list `requestedLocales` against the locales in `availableLocales` and determines the best available language to meet the request. `availableLocales`, `requestedLocales`, and `relevantExtensionKeys` must be provided as List values, `options` and `localeData` as Records.

The following steps are taken:

1. Let `matcher` be `options`.[[localeMatcher]].
2. If `matcher` is "lookup", then
a. Let \( r \) be \( \text{LookupMatcher}(\text{availableLocales}, \text{requestedLocales}) \).

3. Else,
   a. Let \( r \) be \( \text{BestFitMatcher}(\text{availableLocales}, \text{requestedLocales}) \).

4. Let \( \text{foundLocale} \) be \( r.[[\text{locale}]] \).

5. Let \( \text{result} \) be a new Record.

6. Set \( \text{result} .[[\text{dataLocale}]] \) to \( \text{foundLocale} \).

7. If \( r \) has an [[extension]] field, then
   a. Let \( \text{components} \) be \( \text{UnicodeExtensionComponents}(r.[[\text{extension}]]). \)
   b. Let \( \text{keywords} \) be \( \text{components} .[[\text{Keywords}]] \).

8. Let \( \text{supportedExtension} \) be "-u".

9. For each element \( \text{key} \) of \( \text{relevantExtensionKeys} \), do
   a. Let \( \text{foundLocaleData} \) be \( \text{localeData}.[[<\text{foundLocale}>]] \).
   b. Assert: Type(\( \text{foundLocaleData} \)) is Record.
   c. Let \( \text{keyLocaleData} \) be \( \text{foundLocaleData}.[[<\text{key}>]] \).
   d. Assert: Type(\( \text{keyLocaleData} \)) is List.
   e. Let \( \text{value} \) be \( \text{keyLocaleData}[0] \).
   f. Assert: Type(\( \text{value} \)) is either String or Null.
   g. Let \( \text{supportedExtensionAddition} \) be "".
   h. If \( r \) has an [[extension]] field, then
      i. If \( \text{keywords} \) contains an element whose [[Key]] is the same as \( \text{key} \), then
         1. Let \( \text{entry} \) be the element of \( \text{keywords} \) whose [[Key]] is the same as \( \text{key} \).
         2. Let \( \text{requestedValue} \) be \( \text{entry}.[[\text{Value}]] \).
         3. If \( \text{requestedValue} \) is not the empty String, then
            a. If \( \text{keyLocaleData} \) contains \( \text{requestedValue} \), then
               i. Let \( \text{value} \) be \( \text{requestedValue} \).
               ii. Let \( \text{supportedExtensionAddition} \) be the string-concatenation of "-", \( \text{key} \), "-", and \( \text{value} \).
            4. Else if \( \text{keyLocaleData} \) contains "true", then
               a. Let \( \text{value} \) be "true".
               b. Let \( \text{supportedExtensionAddition} \) be the string-concatenation of "-" and \( \text{key} \).
      i. If \( \text{options} \) has a field [[<\text{key}>]], then
         i. Let \( \text{optionsValue} \) be \( \text{options}.[[<\text{key}>]] \).
         ii. Assert: Type(\( \text{optionsValue} \)) is either String, Undefined, or Null.
         iii. If Type(\( \text{optionsValue} \)) is String, then
            1. Let \( \text{optionsValue} \) be the string \( \text{optionsValue} \) after performing the algorithm steps to transform Unicode extension values to canonical syntax per Unicode Technical Standard #35 LDML § 3.2.1 Canonical Unicode Locale Identifiers, treating \( \text{key} \) as \( \text{ukey} \) and \( \text{optionsValue} \) as \( \text{uvalue} \) productions.
            2. Let \( \text{optionsValue} \) be the string \( \text{optionsValue} \) after performing the algorithm steps to replace Unicode extension values with their canonical form per Unicode Technical Standard #35 LDML § 3.2.1 Canonical Unicode Locale Identifiers, treating \( \text{key} \) as \( \text{ukey} \) and \( \text{optionsValue} \) as \( \text{uvalue} \) productions.
            3. If \( \text{optionsValue} \) is the empty String, then
               a. Let \( \text{optionsValue} \) be "true".
         iv. If \( \text{keyLocaleData} \) contains \( \text{optionsValue} \), then
            1. If SameValue(\( \text{optionsValue}, \text{value} \)) is false, then
               a. Let \( \text{value} \) be \( \text{optionsValue} \).
               b. Let \( \text{supportedExtensionAddition} \) be "".
j. Set `result.[<key>]]` to `value`.

k. Append `supportedExtensionAddition` to `supportedExtension`.

10. If the number of elements in `supportedExtension` is greater than 2, then
   a. Let `foundLocale` be `InsertUnicodeExtensionAndCanonicalize(foundLocale, supportedExtension)`.

11. Set `result.[locale]]` to `foundLocale`.

12. Return `result`.

**NOTE** Non-normative summary: Two algorithms are available to match the locales: the Lookup algorithm described in RFC 4647 section 3.4, and an implementation dependent best-fit algorithm. Independent of the locale matching algorithm, options specified through Unicode locale extension sequences are negotiated separately, taking the caller’s relevant extension keys and locale data as well as client-provided options into consideration. The abstract operation returns a record with a [[locale]] field whose value is the language tag of the selected locale, and fields for each key in `relevantExtensionKeys` providing the selected value for that key.

### 9.2.8 LookupSupportedLocales (availableLocales, requestedLocales)

The LookupSupportedLocales abstract operation returns the subset of the provided BCP 47 language priority list `requestedLocales` for which `availableLocales` has a matching locale when using the BCP 47 Lookup algorithm. Locales appear in the same order in the returned list as in `requestedLocales`. The following steps are taken:

1. Let `subset` be a new empty List.
2. For each element `locale` of `requestedLocales`, do
   a. Let `noExtensionsLocale` be the String value that is `locale` with any Unicode locale extension sequences removed.
   b. Let `availableLocale` be `! BestAvailableLocale(availableLocales, noExtensionsLocale)`.
   c. If `availableLocale` is not `undefined`, append `locale` to the end of `subset`.
3. Return `subset`.

### 9.2.9 BestFitSupportedLocales (availableLocales, requestedLocales)

The BestFitSupportedLocales abstract operation returns the subset of the provided BCP 47 language priority list `requestedLocales` for which `availableLocales` has a matching locale when using the Best Fit Matcher algorithm. Locales appear in the same order in the returned list as in `requestedLocales`. The steps taken are implementation dependent.

### 9.2.10 SupportedLocales (availableLocales, requestedLocales, options)

The SupportedLocales abstract operation returns the subset of the provided BCP 47 language priority list `requestedLocales` for which `availableLocales` has a matching locale. Two algorithms are available to match the locales: the Lookup algorithm described in RFC 4647 section 3.4, and an implementation dependent best-fit algorithm. Locales appear in the same order in the returned list as in `requestedLocales`. The following steps are taken:

1. Set `options` to `? CoerceOptionsToObject(options)`.
3. If `matcher` is "best fit", then
   a. Let `supportedLocales` be `BestFitSupportedLocales(availableLocales, requestedLocales)`.
4. Else,
   a. Let supportedLocales be LookupSupportedLocales(availableLocales, requestedLocales).
5. Return ! CreateArrayFromList(supportedLocales).

9.2.11 GetOptionsObject (options)

The abstract operation GetOptionsObject returns an Object suitable for use with GetOption, either options itself or a default empty Object. It throws a TypeError if options is not undefined and not an Object.

1. If options is undefined, then
   a. Return ! OrdinaryObjectCreate(null).
2. If Type(options) is Object, then
   a. Return options.
3. Throw a TypeError exception.

9.2.12 CoerceOptionsToObject (options)

The abstract operation CoerceOptionsToObject coerces options into an Object suitable for use with GetOption, defaulting to an empty Object. Because it coerces non-null primitive values into objects, its use is discouraged for new functionality in favour of GetOptionsObject.

1. If options is undefined, then
   a. Return ! OrdinaryObjectCreate(null).
2. Return ?ToObject(options).

9.2.13 GetOption (options, property, type, values, fallback)

The abstract operation GetOption extracts the value of the property named property from the provided options object, converts it to the required type, checks whether it is one of a List of allowed values, and fills in a fallback value if necessary. If values is undefined, there is no fixed set of values and any is permitted.

1. Assert: Type(options) is Object.
2. Let value be ? Get(options, property).
3. If value is undefined, return fallback.
4. Assert: type is "boolean" or "string".
5. If type is "boolean", then
   a. Set value to ! ToBoolean(value).
6. If type is "string", then
   a. Set value to ? ToString(value).
7. If values is not undefined and values does not contain an element equal to value, throw a RangeError exception.
8. Return value.

9.2.14 DefaultNumberOption (value, minimum, maximum, fallback)

The abstract operation DefaultNumberOption converts value to a Number value, checks whether it is in the allowed range, and fills in a fallback value if necessary.

1. If value is undefined, return fallback.
2. Set `value` to `? ToNumber(value)`.
3. If `value` is NaN or less than `minimum` or greater than `maximum`, throw a `RangeError` exception.
4. Return `floor(value)`.

### 9.2.15 GetNumberOption (options, property, minimum, maximum, fallback)

The abstract operation `GetNumberOption` extracts the value of the property named `property` from the provided `options` object, converts it to a `Number` value, checks whether it is in the allowed range, and fills in a `fallback` value if necessary.

1. Assert: Type(`options`) is Object.
2. Let `value` be `? Get(options, property)`.
3. Return `? DefaultNumberOption(value, minimum, maximum, fallback)`.

### 9.2.16 PartitionPattern (pattern)

The `PartitionPattern` abstract operation is called with argument `pattern`. This abstract operation parses an abstract pattern string into a list of Records with two fields, `[[Type]]` and `[[Value]]`. The `[[Value]]` field will be a String value if `[[Type]]` is "literal", and `undefined` otherwise. The syntax of the abstract pattern strings is an implementation detail and is not exposed to users of ECMA-402. The following steps are taken:

1. Let `result` be a new empty List.
2. Let `beginIndex` be `! StringIndexOf(pattern, "\{", 0)`.
3. Let `endIndex` be 0.
4. Let `nextIndex` be 0.
5. Let `length` be the number of code units in `pattern`.
6. Repeat, while `beginIndex` is an integer index into `pattern`,
   a. Set `endIndex` to `! StringIndexOf(pattern, ",\}", beginIndex)`.
   b. Assert: `endIndex` is greater than `beginIndex`.
   c. If `beginIndex` is greater than `nextIndex`, then
      i. Let `literal` be a substring of `pattern` from position `nextIndex`, inclusive, to position `beginIndex`, exclusive.
      ii. Append a new Record { `[[Type]]": "literal", `[[Value]]": literal } as the last element of the list `result`.
   d. Let `p` be the substring of `pattern` from position `beginIndex` to `endIndex`, exclusive.
   e. Append a new Record { `[[Type]]": p, `[[Value]]": undefined } as the last element of the list `result`.
   f. Set `nextIndex` to `endIndex + 1`.
   g. Set `beginIndex` to `! StringIndexOf(pattern, ",\}", nextIndex)`.
7. If `nextIndex` is less than `length`, then
   a. Let `literal` be the substring of `pattern` from position `nextIndex`, inclusive, to position `length`, exclusive.
   b. Append a new Record { `[[Type]]": "literal", `[[Value]]": literal } as the last element of the list `result`.
8. Return `result`.

## 10 Collator Objects

### 10.1 The Intl.Collator Constructor

© Ecma International
The Intl.Collator constructor is the %Collator% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

### 10.1.1 Intl.Collator ([ locales [, options ] ])

When the Intl.Collator function is called with optional arguments locales and options, the following steps are taken:

1. If NewTarget is undefined, let newTarget be the active function object, else let newTarget be NewTarget.
2. Let internalSlotsList be « [[InitializedCollator]], [[Locale]], [[Usage]], [[Sensitivity]], [[IgnorePunctuation]], [[Collation]], [[BoundCompare]] ».
3. If %Collator%.[[RelevantExtensionKeys]] contains "kn", then
   a. Append [[Numeric]] as the last element of internalSlotsList.
4. If %Collator%.[[RelevantExtensionKeys]] contains "kf", then
   a. Append [[CaseFirst]] as the last element of internalSlotsList.
5. Let collator be ? OrdinaryCreateFromConstructor(newTarget, "%Collator.prototype", internalSlotsList).

### 10.1.2 InitializeCollator ( collator, locales, options )

The abstract operation InitializeCollator accepts the arguments collator (which must be an object), locales, and options. It initializes collator as a Collator object. The following steps are taken:

The following algorithm refers to the type nonterminal from UTS 35's Unicode Locale Identifier grammar.

1. Let requestedLocales be ? CanonicalizeLocaleList(locales).
2. Set options to ? CoerceOptionsToObject(options).
4. Set collator.[[Usage]] to usage.
5. If usage is "sort", then
   a. Let localeData be %Collator%.[[SortLocaleData]].
6. Else,
   a. Let localeData be %Collator%.[[SearchLocaleData]].
7. Let opt be a new Record.
9. Set opt.[[localeMatcher]] to matcher.
11. If collation is not undefined, then
    a. If collation does not match the Unicode Locale Identifier type nonterminal, throw a RangeError exception.
12. Set opt.[[co]] to collation.
14. If numeric is not undefined, then
    a. Let numeric be ! ToString(numeric).
15. Set opt.[[kn]] to numeric.
17. Set opt.[[kf]] to caseFirst.
18. Let relevantExtensionKeys be %Collator%.[[RelevantExtensionKeys]].
19. Let \( r \) be ResolveLocale(%Collator%.[[AvailableLocales]], requestedLocales, opt, relevantExtensionKeys, localeData).
20. Set \( \text{collator}.[[\text{Locale}]] \) to \( r.[[\text{locale}]] \).
21. Let \( \text{collation} \) be \( r.[[\text{co}]] \).
22. If \( \text{collation} \) is null, let \( \text{collation} \) be "default".
23. Set \( \text{collator}.[[\text{Collation}]] \) to \( \text{collation} \).
24. If \( \text{relevantExtensionKeys} \) contains "kn'", then
   a. Set \( \text{collator}.[[\text{Numeric}]] \) to ! SameValue(\( r.[[\text{kn}]] \), "true").
25. If \( \text{relevantExtensionKeys} \) contains "kf'", then
   a. Set \( \text{collator}.[[\text{CaseFirst}]] \) to \( r.[[\text{kf}]] \).
27. If \( \text{sensitivity} \) is undefined, then
   a. If \( \text{usage} \) is "sort", then
      i. Let \( \text{sensitivity} \) be "variant".
   b. Else,
      i. Let \( \text{dataLocale} \) be \( r.[[\text{dataLocale}]] \).
      ii. Let \( \text{dataLocaleData} \) be localeData.[[<\text{dataLocale}>]]
      iii. Let \( \text{sensitivity} \) be \( \text{dataLocaleData}[[\text{sensitivity}]] \).
28. Set \( \text{collator}.[[\text{Sensitivity}]] \) to \( \text{sensitivity} \).
29. Let \( \text{ignorePunctuation} \) be ? GetOption(options, "ignorePunctuation", "boolean", undefined, false).
30. Set \( \text{collator}.[[\text{IgnorePunctuation}]] \) to \( \text{ignorePunctuation} \).
31. Return \( \text{collator} \).

10.2 Properties of the Intl.Collator Constructor

The Intl.Collator constructor has the following properties:

10.2.1 Intl.Collator.prototype

The value of \( \text{Intl.Collator.prototype} \) is %Collator.prototype%. This property has the attributes { [[Writable]: false, [[Enumerable]: false, [[Configurable]: false]}. 

10.2.2 Intl.Collator.supportedLocalesOf ( locales [, options ] )

When the \( \text{supportedLocalesOf} \) method is called with arguments locales and options, the following steps are taken:

1. Let \( \text{availableLocales} \) be %Collator%.[[AvailableLocales]].
2. Let \( \text{requestedLocales} \) be ? CanonicalizeLocaleList(locales).

10.2.3 Internal slots

The value of the [[AvailableLocales]] internal slot is implementation-defined within the constraints described in 9.1. The value of the [[relevantExtensionKeys]] internal slot is a List that must include the element "co", may
include any or all of the elements "kf" and "kn", and must not include any other elements.

NOTE Unicode Technical Standard 35 describes ten locale extension keys that are relevant to collation: "co" for collator usage and specializations, "ka" for alternate handling, "kb" for backward second level weight, "kc" for case level, "kf" for case first, "kh" for hiragana quaternary, "kk" for normalization, "kn" for numeric, "kr" for reordering, "ks" for collation strength, and "vt" for variable top. Collator, however, requires that the usage is specified through the "usage" property of the options object, alternate handling through the "ignorePunctuation" property of the options object, and case level and the strength through the "sensitivity" property of the options object. The "co" key in the language tag is supported only for collator specializations, and the keys "kb", "kh", "kk", "kr", and "vt" are not allowed in this version of the Internationalization API. Support for the remaining keys is implementation dependent.

The values of the [[SortLocaleData]] and [[SearchLocaleData]] internal slots are implementation-defined within the constraints described in 9.1 and the following additional constraints, for all locale values locale:

- The first element of [[SortLocaleData]].[[locale]].[co] and [[SearchLocaleData]].[[locale]].[co] must be null.
- The values "standard" and "search" must not be used as elements in any [[SortLocaleData]].[[locale]].[co] and [[SearchLocaleData]].[[locale]].[co] list.
- [[SearchLocaleData]].[[locale]] must have a [[sensitivity]] field with a String value equal to "base", "accent", "case", or "variant".

10.3 Properties of the Intl.Collator Prototype Object

The Intl.Collator prototype object is itself an ordinary object. %Collator.prototype% is not an Intl.Collator instance and does not have an [[InitializedCollator]] internal slot or any of the other internal slots of Intl.Collator instance objects.

10.3.1 Intl.Collator.prototype.constructor

The initial value of Intl.Collator.prototype.constructor is %Collator%.

10.3.2 Intl.Collator.prototype [ @@toStringTag ]

The initial value of the @@toStringTag property is the String value "Intl.Collator".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

10.3.3 get Intl.Collator.prototype.compare

This named accessor property returns a function that compares two strings according to the sort order of this Collator object.

Intl.Collator.prototype.compare is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let collator be the this value.
2. Perform `RequireInternalSlot(collator, [[InitializedCollator]])`.
3. If `collator.([[BoundCompare]])` is `undefined`, then
   a. Let `F` be a new built-in function object as defined in 10.3.3.1.
   b. Set `F.([Collator])` to `collator`.
   c. Set `collator.([[BoundCompare]])` to `F`.
4. Return `collator.([[BoundCompare]])`.

**NOTE** The returned function is bound to `collator` so that it can be passed directly to `Array.prototype.sort` or other functions.

### 10.3.3.1 Collator Compare Functions

A Collator compare function is an anonymous built-in function that has a `[[Collator]]` internal slot.

When a Collator compare function `F` is called with arguments `x` and `y`, the following steps are taken:

1. Let `collator` be `F.([Collator])`.
2. Assert: `Type(collator)` is Object and `collator` has an `[[InitializedCollator]]` internal slot.
3. If `x` is not provided, let `x` be `undefined`.
4. If `y` is not provided, let `y` be `undefined`.
5. Let `X` be `? ToString(x)`.
7. Return `CompareStrings(collator, X, Y)`.

The "length" property of a Collator compare function is 2.

### 10.3.3.2 CompareStrings (collator, x, y)

When the `CompareStrings` abstract operation is called with arguments `collator` (which must be an object initialized as a Collator), `x` and `y` (which must be String values), it returns a Number other than NaN that represents the result of a locale-sensitive String comparison of `x` with `y`. The two Strings are compared in an implementation-defined fashion. The result is intended to order String values in the sort order specified by the effective locale and collation options computed during construction of `collator`, and will be negative, zero, or positive, depending on whether `x` comes before `y` in the sort order, the Strings are equal under the sort order, or `x` comes after `y` in the sort order, respectively. String values must be interpreted as UTF-16 code unit sequences, and a surrogate pair (a code unit in the range 0xD800 to 0xDBFF followed by a code unit in the range 0xDC00 to 0xDFFF) within a string must be interpreted as the corresponding code point.

The sensitivity of `collator` is interpreted as follows:

- **base**: Only strings that differ in base letters compare as unequal. Examples: `a ≠ b`, `a = á`, `a = A`.
- **accent**: Only strings that differ in base letters or accents and other diacritic marks compare as unequal. Examples: `a ≠ b`, `a = á`, `a = A`.
- **case**: Only strings that differ in base letters or case compare as unequal. Examples: `a ≠ b`, `a = á`, `a ≠ A`.
- **variant**: Strings that differ in base letters, accents and other diacritic marks, or case compare as unequal. Other differences may also be taken into consideration. Examples: `a ≠ b`, `a ≠ á`, `a ≠ A`.

**NOTE 1** In some languages, certain letters with diacritic marks are considered base letters. For example, in Swedish, "ö" is a base letter that's different from "o".
If the collator is set to ignore punctuation, then strings that differ only in punctuation compare as equal.

For the interpretation of options settable through extension keys, see Unicode Technical Standard 35.

The CompareStrings abstract operation with any given `collator` argument, if considered as a function of the remaining two arguments `x` and `y`, must be a consistent comparison function (as defined in es2022, 22.1.3.27) on the set of all Strings.

The actual return values are implementation-defined to permit implementers to encode additional information in the value. The method is required to return `+0𝔽` when comparing Strings that are considered canonically equivalent by the Unicode Standard.

NOTE 2  It is recommended that the CompareStrings abstract operation be implemented following Unicode Technical Standard 10, Unicode Collation Algorithm (available at https://unicode.org/reports/tr10/), using tailorings for the effective locale and collation options of `collator`. It is recommended that implementations use the tailorings provided by the Common Locale Data Repository (available at https://cldr.unicode.org/).

NOTE 3  Applications should not assume that the behaviour of the CompareStrings abstract operation for Collator instances with the same resolved options will remain the same for different versions of the same implementation.

### 10.3.4 Intl.Collator.prototype.resolvedOptions ()

This function provides access to the locale and options computed during initialization of the object.

1. Let `collator` be the `this` value.
3. Let `options` be `! OrdinaryObjectCreate(%Object.prototype%)`.
4. For each row of Table 3, except the header row, in table order, do
   a. Let `p` be the Property value of the current row.
   b. Let `v` be the value of `collator`'s internal slot whose name is the Internal Slot value of the current row.
   c. If the current row has an Extension Key value, then
      i. Let `extensionKey` be the Extension Key value of the current row.
      ii. If `%Collator%.[[RelevantExtensionKeys]]` does not contain `extensionKey`, then
         1. Let `v` be `undefined`.
   d. If `v` is not `undefined`, then
      i. Perform `! CreateDataPropertyOrThrow(options, p, v)`.
5. Return `options`.

<table>
<thead>
<tr>

</tbody>
</table>
### 10.4 Properties of Intl.Collator Instances

Intl.Collator instances are ordinary objects that inherit properties from `%Collator.prototype%`. 

Intl.Collator instances have an `[[InitializedCollator]]` internal slot.

Intl.Collator instances also have several internal slots that are computed by the constructor:

- `[[Locale]]` is a String value with the language tag of the locale whose localization is used for collation.
- `[[Usage]]` is one of the String values "sort" or "search", identifying the collator usage.
- `[[Sensitivity]]` is one of the String values "base", "accent", "case", or "variant", identifying the collator's sensitivity.
- `[[IgnorePunctuation]]` is a Boolean value, specifying whether punctuation should be ignored in comparisons.
- `[[Collation]]` is a String value with the "type" given in Unicode Technical Standard 35 for the collation, except that the values "standard" and "search" are not allowed, while the value "default" is allowed.

Intl.Collator instances also have the following internal slots if the key corresponding to the name of the internal slot in Table 3 is included in the `[[RelevantExtensionKeys]]` internal slot of Intl.Collator:

- `[[Numeric]]` is a Boolean value, specifying whether numeric sorting is used.
- `[[CaseFirst]]` is one of the String values "upper", "lower", or "false".

Finally, Intl.Collator instances have a `[[BoundCompare]]` internal slot that caches the function returned by the `compare` accessor (10.3.3).

### 11 DateTimeFormat Objects

#### 11.1 The Intl.DateTimeFormat Constructor

The Intl.DateTimeFormat constructor is the `%DateTimeFormat%` intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

#### 11.1.1 Intl.DateTimeFormat ([ locales [, options ] ])

When the `Intl.DateTimeFormat` function is called with optional arguments `locales` and `options`, the following steps are taken:

© Ecma International
1. If `newTarget` is `undefined`, let `newTarget` be the active function object, else let `newTarget` be `NewTarget`.

2. Let `dateTimeFormat` be `? OrdinaryCreateFromConstructor(newTarget, "%DateTimeFormat.prototype\%")`, «[[InitializedDateTimeFormat]], [[Locale]], [[Calendar]], [[NumberingSystem]], [[TimeZone]], [[Weekday]], [[Era]], [[Year]], [[Month]], [[Day]], [[DayPeriod]], [[Hour]], [[Minute]], [[Second]], [[FractionalSecondDigits]], [[TimeZoneName]], [[HourCycle]], [[Pattern]], [[BoundFormat]] ».

3. Perform `? InitializeDateTimeFormat(dateTimeFormat, locales, options)`.

4. If the implementation supports the normative optional constructor mode of 4.3 Note 1, then
   a. Let `this` be the `this` value.
   b. Return `? ChainDateTimeFormat(dateTimeFormat, NewTarget, this)`.

5. Return `dateTimeFormat`.

---

**NORMATIVE OPTIONAL**

### 11.1.1 ChainDateTimeFormat (dateTimeFormat, newTarget, this)

1. If `newTarget` is `undefined` and `? OrdinaryHasInstance(%DateTimeFormat%, this)` is `true`, then
   a. Perform `? DefinePropertyOrThrow(this, %Intl%.[[FallbackSymbol]], PropertyDescriptor{ [[Value]]: dateTimeFormat, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false })`.
   b. Return `this`.

2. Return `dateTimeFormat`.

### 11.1.2 InitializeDateTimeFormat (dateTimeFormat, locales, options)

The abstract operation `InitializeDateTimeFormat` accepts the arguments `dateTimeFormat` (which must be an object), `locales`, and `options`. It initializes `dateTimeFormat` as a DateTimeFormat object. This abstract operation functions as follows:

The following algorithm refers to the `type` nonterminal from UTS 35's Unicode Locale Identifier grammar.

1. Let `requestedLocales` be `? CanonicalizeLocaleList(locales)`.
2. Set `options` to `? ToDateTimeOptions(options, "any", "date")`.
3. Let `opt` be a new Record.
5. Set `opt.[[localeMatcher]]` to `matcher`.
7. If `calendar` is not `undefined`, then
   a. If `calendar` does not match the Unicode Locale Identifier `type` nonterminal, throw a `RangeError` exception.
8. Set `opt.[[ca]]` to `calendar`.
9. Let `numberingSystem` be `? GetOption(options, "numberingSystem", "string", undefined, undefined)`.
10. If `numberingSystem` is not `undefined`, then
    a. If `numberingSystem` does not match the Unicode Locale Identifier `type` nonterminal, throw a `RangeError` exception.
11. Set `opt.[[nu]]` to `numberingSystem`.
14. If `hour12` is not `undefined`, then
a. Set `hourCycle` to null.

15. Set `opt.[[hc]]` to `hourCycle`.

16. Let `localeData` be `%DateTimeFormat%.[[LocaleData]].

17. Let `r` be `ResolveLocale(%DateTimeFormat%.[[AvailableLocales]], requestedLocales, opt, %DateTimeFormat%.[[RelevantExtensionKeys]], localeData).

18. Set `dateTimeFormat.[[Locale]]` to `r.[[locale]]`.

19. Set `calendar` to `r.[[ca]]`.

20. Set `dateTimeFormat.[[Calendar]]` to `calendar`.

21. Set `dateTimeFormat.[[NumberingSystem]]` to `r.[[nu]]`.

22. Let `dataLocale` be `r.[[dataLocale]]`.

23. Let `dataLocaleData` be `localeData.[[<dataLocale>]]`.

24. Let `hcDefault` be `dataLocaleData.[[hourCycle]]`.

25. If `r.[[hc]]` is null, then
   a. Let `hc` be `hcDefault`.

26. If `hour12` is true, then
   a. If `hcDefault` is "h11" or "h23", then
      i. Let `hc` be "h11".
   b. Else,
      i. Let `hc` be "h12".

27. Else if `hour12` is false, then
   a. If `hcDefault` is "h11" or "h23", then
      i. Let `hc` be "h23".
   b. Else,
      i. Let `hc` be "h24".

28. Else,
   a. Let `hc` be `r.[[hc]]`.
   b. Assert: `hour12` is undefined.

29. Set `dateTimeFormat.[[HourCycle]]` to `hc`.

30. Let `formatOptions` be a new Record.

31. Set `formatOptions.[[hourCycle]]` to `hc`.

32. Let `timeZone` be ? `Get(options, "timeZone")`.

33. If `timeZone` is undefined, then
   a. Set `timeZone` to ! `DefaultTimeZone()`.

34. Else,
   a. Set `timeZone` to ? `ToString(timeZone)`.
   b. If the result of ! `IsValidTimeZoneName(timeZone)` is false, then
      i. Throw a `RangeError` exception.
   c. Set `timeZone` to ! `CanonicalizeTimeZoneName(timeZone)`.

35. Set `dateTimeFormat.[[TimeZone]]` to `timeZone`.

36. Let `hasExplicitFormatComponents` be false.

37. For each row of Table 6, except the header row, in table order, do
   a. Let `prop` be the name given in the Property column of the row.
   b. If `prop` is "fractionalSecondDigits", then
      i. Let `value` be ? `GetNumberOption(options, "fractionalSecondDigits", 1, 3, undefined)`.
   c. Else,
      i. Let `values` be a List whose elements are the strings given in the Values column of the row.
      ii. Let `value` be ? `GetOption(options, prop, "string", values, undefined)`.
   d. Set `formatOptions.[[<prop>]]` to `value`.

© Ecma International
e. If value is not undefined, then
   i. Set hasExplicitFormatComponents to true.
38. Let matcher be ? GetOption(options, "formatMatcher", "string", « "basic", "best fit" », "best fit").
40. Set dateTimeFormat.[[DateStyle]] to dateStyle.
42. Set dateTimeFormat.[[TimeStyle]] to timeStyle.
43. If dateStyle is not undefined or timeStyle is not undefined, then
   a. If hasExplicitFormatComponents is true, then
      i. Throw a TypeError exception.
   b. Let styles be dataLocaleData.[[styles]].[[calendar]].
   c. Let bestFormat be DateTimeStyleFormat(dateStyle, timeStyle, styles).
44. Else,
   a. Let formats be dataLocaleData.[[formats]].[[calendar]].
   b. If matcher is "basic", then
      i. Let bestFormat be BasicFormatMatcher(formatOptions, formats).
   c. Else,
      i. Let bestFormat be BestFitFormatMatcher(formatOptions, formats).
45. For each row in Table 6, except the header row, in table order, do
   a. Let prop be the name given in the Property column of the row.
   b. If bestFormat has a field [[prop]], then
      i. Let p be bestFormat.[[prop]].
      ii. Set dateTimeFormat's internal slot whose name is the Internal Slot column of the row to p.
46. If dateTimeFormat.[[Hour]] is undefined, then
   a. Set dateTimeFormat.[[HourCycle]] to undefined.
47. If dateTimeFormat.[[HourCycle]] is "h11" or "h12", then
   a. Let pattern be bestFormat.[[pattern12]].
   b. Let rangePatterns be bestFormat.[[rangePatterns12]].
48. Else,
   a. Let pattern be bestFormat.[[pattern]].
   b. Let rangePatterns be bestFormat.[[rangePatterns]].
49. Set dateTimeFormat.[[Pattern]] to pattern.
50. Set dateTimeFormat.[[RangePatterns]] to rangePatterns.
51. Return dateTimeFormat.

11.2 Properties of the Intl.DateTimeFormat Constructor

The Intl.DateTimeFormat constructor has the following properties:

11.2.1 Intl.DateTimeFormat.prototype

The value of Intl.DateTimeFormat.prototype is %DateTimeFormat.prototype%. This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }. © Ecma International
11.2.2 Intl.DateTimeFormat.supportedLocalesOf (locales [, options ])

When the supportedLocalesOf method is called with arguments locales and options, the following steps are taken:

1. Let availableLocales be %DateTimeFormat%.[AvailableLocales].
2. Let requestedLocales be ? CanonicalizeLocaleList(locales).

11.2.3 Internal slots

The value of the [[AvailableLocales]] internal slot is implementation-defined within the constraints described in 9.1.

The value of the [[RelevantExtensionKeys]] internal slot is « "ca", "hc", "nu" ».

NOTE 1 Unicode Technical Standard 35 describes four locale extension keys that are relevant to date and time formatting: "ca" for calendar, "hc" for hour cycle, "nu" for numbering system (of formatted numbers), and "tz" for time zone. DateTimeFormat, however, requires that the time zone is specified through the "timeZone" property in the options objects.

The value of the [[LocaleData]] internal slot is implementation-defined within the constraints described in 9.1 and the following additional constraints, for all locale values locale:

- [[LocaleData]].[<locale>].[nu] must be a List that does not include the values "native", "traditio", or "finance".
- [[LocaleData]].[<locale>].[hc] must be « null, "h11", "h12", "h23", "h24" ».
- [[LocaleData]].[<locale>].[hourCycle] must be a String value equal to "h11", "h12", "h23", or "h24".
- [[LocaleData]].[<locale>]] must have a [[formats]] field. This [[formats]] field must be a Record with [[calendar]] fields for all calendar values calendar. The value of this field must be a list of records, each of which has a subset of the fields shown in Table 6, where each field must have one of the values specified for the field in Table 6. Multiple records in a list may use the same subset of the fields as long as they have different values for the fields. The following subsets must be available for each locale:
  - weekday, year, month, day, hour, minute, second, fractionalSecondDigits
  - weekday, year, month, day, hour, minute, second
  - weekday, year, month, day
  - year, month, day
  - hour, minute, second, fractionalSecondDigits
  - hour, minute, second
  - hour, minute
  - dayPeriod, hour
  - dayPeriod, hour, minute, second
  - dayPeriod, hour, minute

Each of the records must also have the following fields:

1. A [[pattern]] field, whose value is a String value that contains for each of the date and time format component fields of the record a substring starting with "\{", followed by the name of the field, followed by "}".
2. If the record has an [[hour]] field, it must also have a [[pattern12]] field, whose value is a String value that, in addition to the substrings of the [[pattern]] field, contains at least one of the substrings "[ampm]" or "[dayPeriod]".

3. If the record has a [[year]] field, the [[pattern]] and [[pattern12]] values may contain the substrings "[yearName]" and "[relatedYear]".

4. A [[rangePatterns]] field with a Record value:
   - The [[rangePatterns]] record may have any of the fields in Table 4, where each field represents a range pattern and its value is a Record.
     - The name of the field indicates the largest calendar element that must be different between the start and end dates in order to use this range pattern. For example, if the field name is [[Month]], it contains the range pattern that should be used to format a date range where the era and year values are the same, but the month value is different.
     - The record will contain the following fields:
       - A subset of the fields shown in the Property column of Table 6, where each field must have one of the values specified for that field in the Values column of Table 6. All fields required to format a date for any of the [[PatternParts]] records must be present.
       - A [[PatternParts]] field whose value is a list of Records each representing a part of the range pattern. Each record contains a [[Pattern]] field and a [[Source]] field. The [[Pattern]] field’s value is a String of the same format as the regular date pattern String. The [[Source]] field is one of the String values "shared", "startRange", or "endRange". It indicates which of the range’s dates should be formatted using the value of the [[Pattern]] field.
   - The [[rangePatterns]] record must have a [[Default]] field which contains the default range pattern used when the specific range pattern is not available. Its value is a list of records with the same structure as the other fields in the [[rangePatterns]] record.

5. If the record has an [[hour]] field, it must also have a [[rangePatterns12]] field. Its value is similar to the Record in [[rangePatterns]], but it uses a String similar to [[pattern12]] for each part of the range pattern.

6. If the record has a [[year]] field, the [[rangePatterns]] and [[rangePatterns12]] fields may contain range patterns where the [[Pattern]] values may contain the substrings "[yearName]" and "[relatedYear]".

7. [[LocaleData]].[[locale]] must have a [[styles]] field. The [[styles]] field must be a Record with [[calendar]] fields for all calendar values calendar. The calendar records must contain [[DateFormat]], [[TimeFormat]], [[DateTimeFormat]] and [[DateTimeRangeFormat]] fields, the value of these fields are Records, where each of which has [[full]], [[long]], [[medium]] and [[short]] fields. For [[DateFormat]] and [[TimeFormat]], the value of these fields must be a record, which has a subset of the fields shown in Table 6, where each field must have one of the values specified for the field in Table 6. Each of the records must also have the following fields:
   1. A [[pattern]] field, whose value is a String value that contains for each of the date and time format component fields of the record a substring starting with "[", followed by the name of the field, followed by "]".
   2. If the record has an [[hour]] field, it must also have a [[pattern12]] field, whose value is a String value that, in addition to the substrings of the pattern field, contains at least one of the substrings "[ampm]" or "[dayPeriod]".
   3. A [[rangePatterns]] field that contains a record similar to the one described in the [[formats]] field.
   4. If the record has an [[hour]] field, it must also have a [[rangePatterns12]] field. Its value is similar to the record in [[rangePatterns]] but it uses a string similar to [[pattern12]] for each range pattern.
For [[DateTimeFormat]], the field value must be a string pattern which contains the strings "{{0}}" and "{{1}}". For [[DateTimeRangeFormat]] the value of these fields must be a nested record which also has [[full]], [[long]], [[medium]] and [[short]] fields. The [[full]], [[long]], [[medium]] and [[short]] fields in the enclosing record refer to the date style of the range pattern, while the fields in the nested record refers to the time style of the range pattern. The value of these fields in the nested record is a record with a [[rangePatterns]] field and a [[rangePatterns12]] field which are similar to the [[rangePatterns]] and [[rangePatterns12]] fields in [[DateFormat]] and [[TimeFormat]].

NOTE 2 For example, an implementation might include the following record as part of its English locale data:

- [[hour]]: "numeric"
- [[minute]]: "numeric"
- [[pattern]]: "{{hour}}:{{minute}}"
- [[pattern12]]: "{{hour}}:{{minute}} {{ampm}}"
- [[rangePatterns]]:
  - [[Hour]]:
    - [[hour]]: "numeric"
    - [[minute]]: "numeric"
    - [[PatternParts]]:
      - [[Source]]: "startRange", [[Pattern]]: "{{hour}}:{{minute}}"
      - [[Source]]: "shared", [[Pattern]]: " – "
      - [[Source]]: "endRange", [[Pattern]]: "{{hour}}:{{minute}}"
  - [[Minute]]:
    - [[hour]]: "numeric"
    - [[minute]]: "numeric"
    - [[PatternParts]]:
      - [[Source]]: "startRange", [[Pattern]]: "{{hour}}:{{minute}}"
      - [[Source]]: "shared", [[Pattern]]: " – "
      - [[Source]]: "endRange", [[Pattern]]: "{{hour}}:{{minute}}"
  - [[Default]]:
    - [[year]]: "2-digit"
    - [[month]]: "numeric"
    - [[day]]: "numeric"
    - [[hour]]: "numeric"
    - [[minute]]: "numeric"
    - [[PatternParts]]:
      - [[Source]]: "startRange", [[Pattern]]: "{{day}}/{{month}}/{{year}}, {{hour}}:{{minute}}"
      - [[Source]]: "shared", [[Pattern]]: " – "
      - [[Source]]: "endRange", [[Pattern]]: "{{day}}/{{month}}/{{year}}, {{hour}}:{{minute}}"
- [[rangePatterns12]]:
  - [[Hour]]:

### 11.3 Properties of the Intl.DateTimeFormat Prototype Object
The Intl.DateTimeFormat prototype object is itself an ordinary object. %DateTimeFormat.prototype% is not an Intl.DateTimeFormat instance and does not have an [[InitializedDateTimeFormat]] internal slot or any of the other internal slots of Intl.DateTimeFormat instance objects.

### 11.3.1 Intl.DateTimeFormat.prototype.constructor

The initial value of Intl.DateTimeFormat.prototype.constructor is %DateTimeFormat%.

### 11.3.2 Intl.DateTimeFormat.prototype [ @@toStringTag ]

The initial value of the @@toStringTag property is the String value "Intl.DateTimeFormat".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

### 11.3.3 get Intl.DateTimeFormat.prototype.format

Intl.DateTimeFormat.prototype.format is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let dtf be the this value.
2. If the implementation supports the normative optional constructor mode of 4.3 Note 1, then
   a. Set dtf to ? UnwrapDateTimeFormat(dtf).
3. Perform ? RequireInternalSlot(dtf, [[InitializedDateTimeFormat]]).
4. If dtf.[[BoundFormat]] is undefined, then
   a. Let F be a new built-in function object as defined in DateTime Format Functions (11.5.5).
   b. Set F. [[DateTimeFormat]] to dtf.
   c. Set dtf. [[BoundFormat]] to F.
5. Return dtf. [[BoundFormat]].

**NOTE** The returned function is bound to dtf so that it can be passed directly to Array.prototype.map or other functions. This is considered a historical artefact, as part of a convention which is no longer followed for new features, but is preserved to maintain compatibility with existing programs.

### 11.3.4 Intl.DateTimeFormat.prototype.formatToParts ( date )

When the formatToParts method is called with an argument date, the following steps are taken:

1. Let dtf be the this value.
2. Perform ? RequireInternalSlot(dtf, [[InitializedDateTimeFormat]]).
3. If date is undefined, then
   a. Let x be ! Call(%Date.now%, undefined).
4. Else,
   a. Let x be ? ToNumber(date).
5. Return ? FormatDateTimeToParts(dtf, x).

### 11.3.5 Intl.DateTimeFormat.prototype.formatRange ( startDate, endDate )
When the `formatRange` method is called with arguments `startDate` and `endDate`, the following steps are taken:

1. Let `df` be this value.
2. Perform ? RequireInternalSlot(`df`, [[InitializedDateTimeFormat]]).
3. If `startDate` is `undefined` or `endDate` is `undefined`, throw a `TypeError` exception.
4. Let `x` be ? ToNumber(`startDate`).
5. Let `y` be ? ToNumber(`endDate`).
6. Return ? FormatDateTimeRange(`df`, `x`, `y`).

### 11.3.6 Intl.DateTimeFormat.prototype.formatRangeToParts ( `startDate`, `endDate` )

When the `formatRangeToParts` method is called with arguments `startDate` and `endDate`, the following steps are taken:

1. Let `df` be this value.
2. Perform ? RequireInternalSlot(`df`, [[InitializedDateTimeFormat]]).
3. If `startDate` is `undefined` or `endDate` is `undefined`, throw a `TypeError` exception.
4. Let `x` be ? ToNumber(`startDate`).
5. Let `y` be ? ToNumber(`endDate`).
6. Return ? FormatDateTimeRangeToParts(`df`, `x`, `y`).

### 11.3.7 Intl.DateTimeFormat.prototype.resolvedOptions ( )

This function provides access to the locale and options computed during initialization of the object.

1. Let `df` be the this value.
2. If the implementation supports the normative optional constructor mode of 4.3 Note 1, then
   a. Set `df` to ? UnwrapDateTimeFormat(`df`).
3. Perform ? RequireInternalSlot(`df`, [[InitializedDateTimeFormat]]).
4. Let `options` be ! OrdinaryObjectCreate(%Object.prototype%).
5. For each row of Table 5, except the header row, in table order, do
   a. Let `p` be the Property value of the current row.
   b. If `p` is "hour12", then
      i. Let `hc` be `df`.[[HourCycle]].
      ii. If `hc` is "h11" or "h12", let `v` be `true`.
      iii. Else if, `hc` is "h23" or "h24", let `v` be `false`.
      iv. Else, let `v` be `undefined`.
   c. Else,
      i. Let `v` be the value of `df`'s internal slot whose name is the Internal Slot value of the current row.
   d. If the Internal Slot value of the current row is an Internal Slot value in Table 6, then
      i. If `df`.[[DateStyle]] is not `undefined` or `df`.[[TimeStyle]] is not `undefined`, then
         1. Let `v` be `undefined`.
   e. If `v` is not `undefined`, then
      i. Perform ! CreateDataPropertyOrThrow(`options`, `p`, `v`).
6. Return `options`.

<table>

</thead>
<tbody>
<tr>
<td>&quot;locale&quot;</td>
<td>&quot;locale&quot;</td>
</tr>
</tbody>
</table>

Table 5: Resolved Options of DateTimeFormat Instances

© Ecma International
For web compatibility reasons, if the property "hourCycle" is set, the "hour12" property should be set to `true` when "hourCycle" is "h11" or "h12", or to `false` when "hourCycle" is "h23" or "h24".

**NOTE 1** In this version of the ECMAScript 2022 Internationalization API, the "timeZone" property will be the name of the default time zone if no "timeZone" property was provided in the options object provided to the Intl.DateTimeFormat constructor. The first edition left the "timeZone" property `undefined` in this case.

**NOTE 2** For compatibility with versions prior to the fifth edition, the "hour12" property is set in addition to the "hourCycle" property.

### 11.4 Properties of Intl.DateTimeFormat Instances

Intl.DateTimeFormat instances are ordinary objects that inherit properties from `%DateTimeFormat.prototype%`. © Ecma International
Intl.DateTimeFormat instances have an `[[InitializedDateTimeFormat]]` internal slot.

Intl.DateTimeFormat instances also have several internal slots that are computed by the constructor:

- `[[Locale]]` is a String value with the language tag of the locale whose localization is used for formatting.
- `[[Calendar]]` is a String value with the "type" given in Unicode Technical Standard 35 for the calendar used for formatting.
- `[[NumberingSystem]]` is a String value with the "type" given in Unicode Technical Standard 35 for the numbering system used for formatting.
- `[[TimeZone]]` is a String value with the IANA time zone name of the time zone used for formatting.
- `[[Weekday]], [[Era]], [[Year]], [[Month]], [[Day]], [[DayPeriod]], [[Hour]], [[Minute]], [[Second]], [[TimeZoneName]]` are each either `undefined`, indicating that the component is not used for formatting, or one of the String values given in Table 6, indicating how the component should be presented in the formatted output.
- `[[FractionalSecondDigits]]` is either `undefined` or a positive, non-zero integer `Number` value indicating the fraction digits to be used for fractional seconds. Numbers will be rounded or padded with trailing zeroes if necessary.
- `[[HourCycle]]` is a String value indicating whether the 12-hour format ("h11", "h12") or the 24-hour format ("h23", "h24") should be used. "h11" and "h23" start with hour 0 and go up to 11 and 23 respectively. "h12" and "h24" start with hour 1 and go up to 12 and 24. `[[HourCycle]]` is only used when `[[Hour]]` is not `undefined`.
- `[[DateStyle]], [[TimeStyle]]` are each either `undefined`, or a String value with values "full", "long", "medium", or "short".
- `[[Pattern]]` is a String value as described in 11.2.3.
- `[[RangePatterns]]` is a `Record` as described in 11.2.3.

Finally, Intl.DateTimeFormat instances have a `[[BoundFormat]]` internal slot that caches the function returned by the format accessor (11.3.3).

### 11.5 Abstract Operations for DateTimeFormat Objects

Several DateTimeFormat algorithms use values from the following table, which provides internal slots, property names and allowable values for the components of date and time formats:

<table>
<thead>
<tr>
<th>Internal Slot</th>
<th>Property</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[[Weekday]]</code></td>
<td>&quot;weekday&quot;</td>
<td>&quot;narrow&quot;, &quot;short&quot;, &quot;long&quot;</td>
</tr>
<tr>
<td><code>[[Era]]</code></td>
<td>&quot;era&quot;</td>
<td>&quot;narrow&quot;, &quot;short&quot;, &quot;long&quot;</td>
</tr>
<tr>
<td><code>[[Year]]</code></td>
<td>&quot;year&quot;</td>
<td>&quot;2-digit&quot;, &quot;numeric&quot;</td>
</tr>
<tr>
<td><code>[[Month]]</code></td>
<td>&quot;month&quot;</td>
<td>&quot;2-digit&quot;, &quot;numeric&quot;, &quot;narrow&quot;, &quot;short&quot;, &quot;long&quot;</td>
</tr>
<tr>
<td><code>[[Day]]</code></td>
<td>&quot;day&quot;</td>
<td>&quot;2-digit&quot;, &quot;numeric&quot;</td>
</tr>
<tr>
<td><code>[[DayPeriod]]</code></td>
<td>&quot;dayPeriod&quot;</td>
<td>&quot;narrow&quot;, &quot;short&quot;, &quot;long&quot;</td>
</tr>
<tr>
<td><code>[[Hour]]</code></td>
<td>&quot;hour&quot;</td>
<td>&quot;2-digit&quot;, &quot;numeric&quot;</td>
</tr>
<tr>
<td><code>[[Minute]]</code></td>
<td>&quot;minute&quot;</td>
<td>&quot;2-digit&quot;, &quot;numeric&quot;</td>
</tr>
</tbody>
</table>
11.5.1 ToDateTimeOptions (options, required, defaults)

When the ToDateTimeOptions abstract operation is called with arguments options, required, and defaults, the following steps are taken:

1. If options is undefined, let options be null; otherwise let options be ?ToObject(options).
2. Let options be !OrdinaryObjectCreate(options).
3. Let needDefaults be true.
4. If required is "date" or "any", then
   a. For each property name prop of «"weekday", "year", "month", "day"», do
      i. Let value be Get(options, prop).
      ii. If value is not undefined, let needDefaults be false.
5. If required is "time" or "any", then
   a. For each property name prop of «"dayPeriod", "hour", "minute", "second", "fractionalSecondDigits"», do
      i. Let value be Get(options, prop).
      ii. If value is not undefined, let needDefaults be false.
6. Let dateStyle be ?Get(options, "dateStyle").
7. Let timeStyle be ?Get(options, "timeStyle").
8. If dateStyle is not undefined or timeStyle is not undefined, let needDefaults be false.
9. If required is "date" and timeStyle is not undefined, then
   a. Throw a TypeError exception.
10. If required is "time" and dateStyle is not undefined, then
    a. Throw a TypeError exception.
11. If needDefaults is true and defaults is either "date" or "all", then
    a. For each property name prop of «"year", "month", "day"», do
       i. Perform ?CreateDataPropertyOrThrow(options, prop, "numeric").
12. If needDefaults is true and defaults is either "time" or "all", then
    a. For each property name prop of «"hour", "minute", "second"», do
       i. Perform ?CreateDataPropertyOrThrow(options, prop, "numeric").
13. Return options.

11.5.2 DateTimeStyleFormat (dateStyle, timeStyle, styles)

The DateTimeStyleFormat abstract operation accepts arguments dateStyle and timeStyle, which are each either undefined, "full", "long", "medium", or "short", at least one of which is not undefined, and styles, which is a record from %DateTimeFormat%.[[LocaleData].[[locale]].[[styles]].[[calendar>]]] for some locale locale and calendar calendar. It returns the appropriate format record for date time formatting based on the parameters.
1. If \texttt{timeStyle} is not \texttt{undefined}, then
   a. Assert: \texttt{timeStyle} is one of "full", "long", "medium", or "short".
   b. Let \texttt{timeFormat} be \texttt{styles.[[TimeFormat]].[[<timeStyle>]]}.

2. If \texttt{dateStyle} is not \texttt{undefined}, then
   a. Assert: \texttt{dateStyle} is one of "full", "long", "medium", or "short".
   b. Let \texttt{dateFormat} be \texttt{styles.[[DateFormat]].[[<dateStyle>]]}.

3. If \texttt{dateStyle} is not \texttt{undefined} and \texttt{timeStyle} is not \texttt{undefined}, then
   a. Let \texttt{format} be a new \texttt{Record}.
   b. Add to \texttt{format} all fields from \texttt{dateFormat} except [[pattern]] and [[rangePatterns]].
   c. Add to \texttt{format} all fields from \texttt{timeFormat} except [[pattern]], [[rangePatterns]], [[pattern12]], and
      [[rangePatterns12]], if present.
   d. Let \texttt{connector} be \texttt{styles.[[DateTimeFormat]].[[<dateStyle>]]}.
   e. Let \texttt{pattern} be the string \texttt{connector} with the substring "\texttt{\{0\}" replaced with \texttt{timeFormat.[[pattern]]} and the
      substring "\texttt{\{1\}" replaced with \texttt{dateFormat.[[pattern]]}.
   f. Set \texttt{format.[[pattern]]} to \texttt{pattern}.
   g. If \texttt{timeFormat} has a [[pattern12]] field, then
      i. Let \texttt{pattern12} be the string \texttt{connector} with the substring "\texttt{\{0\}" replaced with \texttt{timeFormat.[[pattern12]]} and the
         substring "\texttt{\{1\}" replaced with \texttt{dateFormat.[[pattern]]}.
      ii. Set \texttt{format.[[pattern12]]} to \texttt{pattern12}.
   h. Let \texttt{dateTimeRangeFormat} be \texttt{styles.[[DateTimeRangeFormat]].[[<dateStyle>]].[[<timeStyle>]]}.
   i. Set \texttt{format.[[rangePatterns]]} to \texttt{dateTimeRangeFormat.[[rangePatterns]]}.
   j. If \texttt{dateTimeRangeFormat} has a [[rangePatterns12]] field, then
      i. Set \texttt{format.[[rangePatterns12]]} to \texttt{dateTimeRangeFormat.[[rangePatterns12]]}.
   k. Return \texttt{format}.

4. If \texttt{timeStyle} is not \texttt{undefined}, then
   a. Return \texttt{timeFormat}.

5. Assert: \texttt{dateStyle} is not \texttt{undefined}.

6. Return \texttt{dateFormat}.

### 11.5.3 BasicFormatMatcher ( \texttt{options, formats} )

When the BasicFormatMatcher abstract operation is called with two arguments \texttt{options} and \texttt{formats}, the
following steps are taken:

1. Let \texttt{removalPenalty} be 120.
2. Let \texttt{additionPenalty} be 20.
3. Let \texttt{longLessPenalty} be 8.
4. Let \texttt{longMorePenalty} be 6.
5. Let \texttt{shortLessPenalty} be 6.
7. Let \texttt{offsetPenalty} be 1.
8. Let \texttt{bestScore} be -\texttt{Infinity}.
9. Let \texttt{bestFormat} be \texttt{undefined}.
10. Assert: \texttt{Type(formats)} is \texttt{List}.
11. For each element \texttt{format} of \texttt{formats}, do
    a. Let \texttt{score} be 0.
    b. For each property name \texttt{property} shown in Table 6, do
i. If `options` has a field `[[<property>]]`, let `optionsProp` be `options.[[<property>]]`; else let `optionsProp` be `undefined`.

ii. If `format` has a field `[[<property>]]`, let `formatProp` be `format.[[<property>]]`; else let `formatProp` be `undefined`.

iii. If `optionsProp` is `undefined` and `formatProp` is not `undefined`, decrease `score` by `additionPenalty`.

iv. Else if `optionsProp` is not `undefined` and `formatProp` is `undefined`, decrease `score` by `removalPenalty`.

v. Else if `property` is "`timeZoneName`", then

1. If `optionsProp` is "`short`" or "`shortGeneric`", then
   a. If `formatProp` is "`shortOffset`", decrease `score` by `offsetPenalty`.
   b. Else if `formatProp` is "`longOffset`", decrease `score` by `(offsetPenalty + shortMorePenalty)`.
   c. Else if `optionsProp` is "`short`" and `formatProp` is "`long`", decrease `score` by `shortMorePenalty`.
   d. Else if `optionsProp` is "`shortGeneric`" and `formatProp` is "`longGeneric`", decrease `score` by `shortMorePenalty`.
   e. Else if `optionsProp != formatProp`, decrease `score` by `removalPenalty`.

2. Else if `optionsProp` is "`shortOffset`" and `formatProp` is "`longOffset`", decrease `score` by `shortMorePenalty`.

3. Else if `optionsProp` is "`long`" or "`longGeneric`", then
   a. If `formatProp` is "`longOffset`", decrease `score` by `offsetPenalty`.
   b. Else if `formatProp` is "`shortOffset`", decrease `score` by `(offsetPenalty + longLessPenalty)`.
   c. Else if `optionsProp` is "`long`" and `formatProp` is "`short`", decrease `score` by `longLessPenalty`.
   d. Else if `optionsProp` is "`longGeneric`" and `formatProp` is "`shortGeneric`", decrease `score` by `longLessPenalty`.
   e. Else if `optionsProp != formatProp`, decrease `score` by `removalPenalty`.

4. Else if `optionsProp` is "`longOffset`" and `formatProp` is "`shortOffset`", decrease `score` by `longLessPenalty`.

5. Else if `optionsProp != formatProp`, decrease `score` by `removalPenalty`.

vi. Else if `optionsProp != formatProp`, then

1. If `property` is "`fractionalSecondDigits`", then
   a. Let `values` be « `1_F`, `2_F`, `3_F` ».
   b. Else,
      a. Let `values` be « "`2-digit`", "numeric", "narrow", "short", "long" ».

3. Let `optionsPropIndex` be the index of `optionsProp` within `values`.

4. Let `formatPropIndex` be the index of `formatProp` within `values`.

5. Let `delta` be `max(min(formatPropIndex - optionsPropIndex, 2), -2)`.

6. If `delta` = `2`, decrease `score` by `longMorePenalty`.

7. Else if `delta` = `-1`, decrease `score` by `shortLessPenalty`.

8. Else if `delta` = `-2`, decrease `score` by `longLessPenalty`.

9. Else if `delta` = `-2`, decrease `score` by `longLessPenalty`.

   c. If `score > bestScore`, then
      i. Let `bestScore` be `score`.
      ii. Let `bestFormat` be `format`.

### 11.5.4 BestFitFormatMatcher ( `options`, `formats` )

When the BestFitFormatMatcher abstract operation is called with two arguments `options` and `formats`, it performs implementation dependent steps, which should return a set of component representations that a
typical user of the selected locale would perceive as at least as good as the one returned by BasicFormatMatcher.

11.5.5 DateTime Format Functions

A DateTime format function is an anonymous built-in function that has a [[DateTimeFormat]] internal slot.

When a DateTime format function $F$ is called with optional argument $date$, the following steps are taken:

1. Let $dtf$ be $F$.[[DateTimeFormat]].
2. Assert: Type($dtf$) is Object and $dtf$ has an [[InitializedDateTimeFormat]] internal slot.
3. If $date$ is not provided or is undefined, then
   a. Let $x$ be Call(%Date.now%, undefined).
4. Else,
   a. Let $x$ be ? ToNumber($date$).
5. Return ? FormatDateTime($dtf$, $x$).

The "length" property of a DateTime format function is 1.

11.5.6 FormatDateTimePattern ($dateTimeFormat$, $patternParts$, $x$, $rangeFormatOptions$)

The FormatDateTimePattern abstract operation is called with arguments $dateTimeFormat$ (which must be an object initialized as a DateTimeFormat), $patternParts$ (which is a list of Records as returned by PartitionPattern), $x$ (which must be a Number value), and $rangeFormatOptions$ (which is a range pattern Record as used in [[rangePattern]] or undefined), interprets $x$ as a time value as specified in es2022, 20.4.1.1, and creates the corresponding parts according to pattern and to the effective locale and the formatting options of $dateTimeFormat$ and $rangeFormatOptions$. The following steps are taken:

1. Let $x$ be TimeClip($x$).
2. If $x$ is NaN, throw a RangeError exception.
3. Let locale be $dateTimeFormat$.[[Locale]].
4. Let $nfOptions$ be ! OrdinaryObjectCreate(null).
5. Perform ! CreateDataPropertyOrThrow($nfOptions$, "useGrouping", false).
6. Let $nf$ be ? Construct(%NumberFormat%, «locale, $nfOptions»).
7. Let $nf2Options$ be ! OrdinaryObjectCreate(null).
8. Perform ! CreateDataPropertyOrThrow($nf2Options$, "minimumIntegerDigits", 2).
9. Perform ! CreateDataPropertyOrThrow($nf2Options$, "useGrouping", false).
10. Let $nf2$ be ? Construct(%NumberFormat%, «locale, $nf2Options»).
11. Let fractionalSecondDigits be $dateTimeFormat$.[[FractionalSecondDigits]].
12. If fractionalSecondDigits is not undefined, then
   a. Let $nf3Options$ be ! OrdinaryObjectCreate(null).
   b. Perform ! CreateDataPropertyOrThrow($nf3Options$, "minimumIntegerDigits", fractionalSecondDigits).
   c. Perform ! CreateDataPropertyOrThrow($nf3Options$, "useGrouping", false).
   d. Let $nf3$ be ? Construct(%NumberFormat%, «locale, $nf3Options»).
13. Let tm beToLocalTime($x$, $dateTimeFormat$.[[Calendar]], $dateTimeFormat$.[[TimeZone]]).
14. Let result be a new empty List.
15. For each Record {[[Type]], [[Value]]} in $patternParts$, do
   a. Let $p$ be $patternPart$.[[Type]].
b. If $p$ is "literal", then
   i. Append a new Record { [[Type]]: "literal", [[Value]]: patternPart.[[Value]] } as the last element of the list result.

c. Else if $p$ is equal to "fractionalSecondDigits", then
   i. Let $v$ be tm.[[Millisecond]].
   ii. Let $v$ be floor($v \times 10(\text{fractionalSecondDigits} - 3)$).
   iii. Append a new Record { [[Type]]: "fractionalSecond", [[Value]]: $fv$ } as the last element of result.

d. Else if $p$ is equal to "dayPeriod", then
   i. Let $f$ be the value of dateTimeFormat's internal slot whose name is the Internal Slot column of the matching row.
   ii. Let $fv$ be a String value representing the day period of $tm$ in the form given by $f$; the String value depends upon the implementation and the effective locale of dateTimeFormat.
   iii. Append a new Record { [[Type]]: $p$, [[Value]]: $fv$ } as the last element of the list result.

e. Else if $p$ is equal to " timeZoneName ", then
   i. Let $f$ be dateTimeFormat.[[TimeZoneName]].
   ii. Let $v$ be dateTimeFormat.[[TimeZone]].
   iii. Let $fv$ be a String value representing $v$ in the form given by $f$; the String value depends upon the implementation and the effective locale of dateTimeFormat. The String value may also depend on the value of the [[InDST]] field of $tm$ if $f$ is " short ", " long ", " shortOffset ", or " longOffset ". If the implementation does not have a localized representation of $f$, then use the String value of $v$ itself.
   iv. Append a new Record { [[Type]]: $p$, [[Value]]: $fv$ } as the last element of the list result.

f. Else if $p$ matches a Property column of the row in Table 6, then
i. If rangeFormatOptions is not undefined, let $f$ be the value of rangeFormatOptions's field whose name matches $p$.
ii. Else, let $f$ be the value of dateTimeFormat's internal slot whose name is the Internal Slot column of the matching row.
iii. Let $v$ be the value of $tm$'s field whose name is the Internal Slot column of the matching row.
iv. If $p$ is "year" and $v \leq 0$, let $v$ be $1 - v$.
v. If $p$ is "month", increase $v$ by 1.
vi. If $p$ is "hour" and dateTimeFormat.[[HourCycle]] is "h11" or "h12", then
   1. Let $v$ be $v$ modulo 12.
   2. If $v$ is 0 and dateTimeFormat.[[HourCycle]] is "h12", let $v$ be 12.

vii. If $p$ is "hour" and dateTimeFormat.[[HourCycle]] is "h24", then
   1. If $v$ is 0, let $v$ be 24.

viii. If $f$ is "numeric", then
   1. Let $fv$ be FormatNumeric($nf$, $v$).
ix. Else if $f$ is "2-digit", then
   1. Let $fv$ be FormatNumeric($nf2$, $v$).
   2. If the "length" property of $fv$ is greater than 2, let $fv$ be the substring of $fv$ containing the last two characters.

x. Else if $f$ is "narrow", "short", or "long", then let $fv$ be a String value representing $v$ in the form given by $f$; the String value depends upon the implementation and the effective locale and calendar of dateTimeFormat. If $p$ is "month" and rangeFormatOptions is undefined, then the String value may also depend on whether dateTimeFormat.[[Day]] is undefined. If $p$ is "month" and rangeFormatOptions is not undefined, then the String value may also depend on whether rangeFormatOptions.[[day]] is undefined. If $p$ is "era" and rangeFormatOptions is undefined, then the String value may also depend on whether dateTimeFormat.[[Era]] is undefined. If $p$ is "era"
and `rangeFormatOptions` is not `undefined`, then the String value may also depend on whether `rangeFormatOptions.\[\{era\}\]` is `undefined`. If the implementation does not have a localized representation of `f`, then use the String value of `v` itself.

xi. Append a new `Record` \([\{Type\}: p, \{Value\}: fo]\) as the last element of the list `result`.

g. Else if `p` is equal to "ampm", then
   i. Let `v` be `tm.\[\{Hour\}\]`.
   ii. If `v` is greater than 11, then
      1. Let `fo` be an implementation and locale dependent String value representing "post meridiem".
   iii. Else,
      1. Let `fo` be an implementation and locale dependent String value representing "ante meridiem".

iv. Append a new `Record` \([\{Type\}: "dayPeriod", \{Value\}: fo\] as the last element of the list `result`.

h. Else if `p` is equal to "relatedYear", then
   i. Let `v` be `tm.\[\{RelatedYear\}\]`.
   ii. Let `fo` be `FormatNumeric(nf, v)`.
   iii. Append a new `Record` \([\{Type\}: "relatedYear", \{Value\}: fo\] as the last element of the list `result`.

i. Else if `p` is equal to "yearName", then
   i. Let `v` be `tm.\[\{YearName\}\]`.
   ii. Let `fo` be an implementation and locale dependent String value representing `v`.
   iii. Append a new `Record` \([\{Type\}: "yearName", \{Value\}: fo\] as the last element of the list `result`.

j. Else,
   i. Let `unknown` be an implementation-, locale-, and numbering system-dependent String based on `x` and `p`.
   ii. Append a new `Record` \([\{Type\}: "unknown", \{Value\}: unknown\] as the last element of `result`.

16. Return `result`.

### NOTE 1
It is recommended that implementations use the locale and calendar dependent strings provided by the Common Locale Data Repository (available at [https://cldr.unicode.org/](https://cldr.unicode.org/)), and use CLDR "abbreviated" strings for DateTimeFormat "short" strings, and CLDR "wide" strings for DateTimeFormat "long" strings.

### NOTE 2
It is recommended that implementations use the time zone information of the IANA Time Zone Database.

#### 11.5.7 PartitionDateTimePattern ( `dateTimeFormat, x` )

The PartitionDateTimePattern abstract operation is called with arguments `dateTimeFormat` (which must be an object initialized as a DateTimeFormat) and `x` (which must be a `Number` value), interprets `x` as a `time value` as specified in es2022, 20.4.1.1, and creates the corresponding parts according to the effective locale and the formatting options of `dateTimeFormat`. The following steps are taken:

1. Let `patternParts` be `PartitionPattern(dateTimeFormat.\[\{Pattern\}\])`.
2. Let `result` be ? `FormatDateTimePattern(dateTimeFormat, patternParts, x, undefined)`.
3. Return `result`.

#### 11.5.8 FormatDateTime ( `dateTimeFormat, x` )
The FormatDateTime abstract operation is called with arguments `dateTimeFormat` (which must be an object initialized as a `DateTimeFormat`) and `x` (which must be a `Number value`), and performs the following steps:

1. Let `parts` be `PartitionDateTimePattern(dateTimeFormat, x)`.
2. Let `result` be the empty String.
3. For each Record `[[Type]], [[Value]] | part` in `parts`, do
   a. Set `result` to the string-concatenation of `result` and `part.[[Value]]`.
4. Return `result`.

### 11.5.9 FormatDateTimeToParts ( `dateTimeFormat, x` )

The FormatDateTimeToParts abstract operation is called with arguments `dateTimeFormat` (which must be an object initialized as a `DateTimeFormat`) and `x` (which must be a `Number value`), and performs the following steps:

1. Let `parts` be `PartitionDateTimePattern(dateTimeFormat, x)`.
2. Let `result` be `ArrayCreate(0)`.
3. Let `n` be 0.
4. For each Record `[[Type]], [[Value]] | part` in `parts`, do
   a. Let `O` be `OrdinaryObjectCreate(%Object.prototype%)`.
   b. Perform `CreateDataPropertyOrThrow(O, "type", part.[[Type]])`.
   c. Perform `CreateDataPropertyOrThrow(O, "value", part.[[Value]])`.
   d. Perform `CreateDataProperty(result, !ToString(n), O)`.
   e. Increment `n` by 1.
5. Return `result`.

### 11.5.10 PartitionDateTimeRangePattern ( `dateTimeFormat, x, y` )

The PartitionDateTimeRangePattern abstract operation is called with arguments `dateTimeFormat` (which must be an object initialized as a `DateTimeFormat`), `x` (which must be a `Number value`) and `y` (which must be a `Number value`), interprets `x` and `y` as time values as specified in es2022, 20.4.1.1, and creates the corresponding parts according to the effective locale and the formatting options of `dateTimeFormat`. The following steps are taken:

1. Let `x` be `TimeClip(x)`.
2. If `x` is `NaN`, throw a `RangeError` exception.
3. Let `y` be `TimeClip(y)`.
4. If `y` is `NaN`, throw a `RangeError` exception.
5. If `x` is greater than `y`, throw a `RangeError` exception.
6. Let `tm1` be `ToLocalTime(x, dateTimeFormat.[[Calendar]], dateTimeFormat.[[TimeZone]])`.
7. Let `tm2` be `ToLocalTime(y, dateTimeFormat.[[Calendar]], dateTimeFormat.[[TimeZone]])`.
8. Let `rangePatterns` be `dateTimeFormat.[[RangePatterns]]`.
9. Let `rangePattern` be `undefined`.
10. Let `dateFieldsPracticallyEqual` be `true`.
11. Let `patternContainsLargerDateField` be `false`.
12. While `dateFieldsPracticallyEqual` is `true` and `patternContainsLargerDateField` is `false`, repeat for each row of Table 4 in order, except the header row:
   a. Let `fieldName` be the name given in the Range Pattern Field column of the row.
   b. If `rangePatterns` has a field `[[<fieldName>]]`, let `rp` be `rangePatterns.[[<fieldName>]]`; else let `rp` be `undefined`.
c. If `rangePattern` is not `undefined` and `rp` is `undefined`, then
   i. Set `patternContainsLargerDateField` to `true`.
d. Else,
   i. Let `rangePattern` be `rp`.
   ii. If `fieldName` is equal to `[[AmPm]]`, then
       1. Let `v1` be `tm1.[[Hour]]`.
       2. Let `v2` be `tm2.[[Hour]]`.
       3. If `v1` is greater than 11 and `v2` less or equal than 11, or `v1` is less or equal than 11 and `v2` is greater than 11, then
          a. Set `dateFieldsPracticallyEqual` to `false`.
   iii. Else if `fieldName` is equal to `[[DayPeriod]]`, then
       1. Let `v1` be a String value representing the day period of `tm1`; the String value depends upon the implementation and the effective locale of `dateTimeFormat`.
       2. Let `v2` be a String value representing the day period of `tm2`; the String value depends upon the implementation and the effective locale of `dateTimeFormat`.
       3. If `v1` is not equal to `v2`, then
          a. Set `dateFieldsPracticallyEqual` to `false`.
   iv. Else if `fieldName` is equal to `[[FractionalSecondDigits]]`, then
       1. Let `fractionalSecondDigits` be `dateTimeFormat.[[FractionalSecondDigits]]`.
       2. If `fractionalSecondDigits` is `undefined`, then
          a. Set `fractionalSecondDigits` to 3.
       3. Let `v1` be `tm1.[[Millisecond]]`.
       4. Let `v2` be `tm2.[[Millisecond]]`.
       5. Let `v1` be `floor(v1 \times 10^{(fractionalSecondDigits - 3)})`.
       6. Let `v2` be `floor(v2 \times 10^{(fractionalSecondDigits - 3)})`.
       7. If `v1` is not equal to `v2`, then
          a. Set `dateFieldsPracticallyEqual` to `false`.
   v. Else,
       1. Let `v1` be `tm1.[<fieldName>]`.
       2. Let `v2` be `tm2.[<fieldName>]`.
       3. If `v1` is not equal to `v2`, then
          a. Set `dateFieldsPracticallyEqual` to `false`.
13. If `dateFieldsPracticallyEqual` is `true`, then
    a. Let `pattern` be `dateTimeFormat.[[Pattern]]`.
    b. Let `patternParts` be `PartitionPattern(pattern)`.
    c. Let `result` be `? FormatDateTimePattern(dateTimeFormat, patternParts, x, undefined)`.
    d. For each Record `{ [[Type]], [[Value]] } r` in `result`, do
       i. Set `r.[[Source]]` to "shared".
    e. Return `result`.
14. Let `result` be a new empty List.
15. If `rangePattern` is `undefined`, then
    a. Let `rangePattern` be `rangePatterns.[[Default]]`.
16. For each Record `{ [[Pattern]], [[Source]] } rangePatternPart` in `rangePattern.[[PatternParts]]`, do
    a. Let `pattern` be `rangePatternPart.[[Pattern]]`.
    b. Let `source` be `rangePatternPart.[[Source]]`.
    c. If `source` is "startRange" or "shared", then
       i. Let `z` be `x`.
    d. Else,
i. Let \( z \) be \( y \).

e. Let \( \text{patternParts} \) be \( \text{PartitionPattern}(\text{pattern}) \).

f. Let \( \text{partResult} \) be \( \text{FormatDateTimePattern}(\text{dateTimeFormat}, \text{patternParts}, z, \text{rangePattern}) \).

g. For each \( \text{Record} \{ [[[\text{Type}]], [[[\text{Value}]]) \ r \} \) in \( \text{partResult} \), do

i. Set \( r.[[\text{Source}]] \) to \( \text{source} \).

h. Add all elements in \( \text{partResult} \) to \( \text{result} \) in order.

17. Return \( \text{result} \).

11.5.11 \text{FormatDateTimeRange ( dateTimeFormat, x, y )}

The \text{FormatDateTimeRange} abstract operation is called with arguments \( \text{dateTimeFormat} \) (which must be an object initialized as a \text{DateTimeFormat}), \( x \) (which must be a \text{Number value}) and \( y \) (which must be a \text{Number value}), and performs the following steps:

1. Let \( \text{parts} \) be \( \text{PartitionDateTimeRangePattern}(\text{dateTimeFormat}, x, y) \).

2. Let \( \text{result} \) be the empty String.

3. For each \( \text{Record} \{ [[[\text{Type}]], [[[\text{Value}]]) \ part \} \) in \( \text{parts} \), do

a. Set \( \text{result} \) to the string-concatenation of \( \text{result} \) and \( \text{part.}[[[\text{Value}]]] \).

4. Return \( \text{result} \).

11.5.12 \text{FormatDateTimeRangeToParts ( dateTimeFormat, x, y )}

The \text{FormatDateTimeRangeToParts} abstract operation is called with arguments \( \text{dateTimeFormat} \) (which must be an object initialized as a \text{DateTimeFormat}), \( x \) (which must be a \text{Number value}) and \( y \) (which must be a \text{Number value}), and performs the following steps:

1. Let \( \text{parts} \) be \( \text{PartitionDateTimeRangePattern}(\text{dateTimeFormat}, x, y) \).

2. Let \( \text{result} \) be \( \text{ArrayCreate}(0) \).

3. Let \( n \) be \( 0 \).

4. For each \( \text{Record} \{ [[[\text{Type}]], [[[\text{Value}]]) \ part \} \) in \( \text{parts} \), do

a. Let \( O \) be \( \text{ OrdinaryObjectCreate}(%\text{object.prototype}%) \).

b. Perform \( \text{CreateDataPropertyOrThrow} (O, "\text{type}", \text{part}_.[[[\text{Type}]]]) \).

c. Perform \( \text{CreateDataPropertyOrThrow} (O, "\text{value}", \text{part}_.[[[\text{Value}]]]) \).

d. Perform \( \text{CreateDataPropertyOrThrow} (O, "\text{source}", \text{part}_.[[[\text{Source}]]]) \).

5. Return \( \text{result} \).

11.5.13 \text{ToLocalTime ( t, calendar, timeZone )}

When the \text{ToLocalTime} abstract operation is called with arguments \( t, \text{calendar}, \) and \( \text{timeZone} \), the following steps are taken:

1. Assert: \( \text{Type}(t) \) is \text{Number}.

2. If \( \text{calendar} \) is "gregory", then

   a. Let \( \text{timeZoneOffset} \) be the value calculated according to \( \text{LocalTZA}(t, \text{true}) \) where the local time zone is replaced with timezone \( \text{timeZone} \).

   b. Let \( tz \) be the \text{time value} \( t + \text{timeZoneOffset} \).
c. Return a record with fields calculated from \( tz \) according to Table 7.

3. Else,
   a. Return a record with the fields of Column 1 of Table 7 calculated from \( t \) for the given \( calendar \) and \( timeZone \). The calculations should use best available information about the specified \( calendar \) and \( timeZone \), including current and historical information about time zone offsets from UTC and daylight saving time rules.

Table 7: Record returned by ToLocalTime

<table>
<thead>
<tr>
<th>Field</th>
<th>Value Calculation for Gregorian Calendar</th>
</tr>

</tbody>
</table>

NOTE It is recommended that implementations use the time zone information of the IANA Time Zone Database.

NORMATIVE OPTIONAL

11.5.14 UnwrapDateTimeFormat ( \( dtf \) )

The UnwrapDateTimeFormat abstract operation returns the DateTimeFormat instance of its input object, which is either the value itself or a value associated with it by \%DateTimeFormat\% according to the normative optional constructor mode of 4.3 Note 1.

1. If Type(\( dtf \)) is not Object, throw a TypeError exception.
2. If \( dtf \) does not have an [[InitializedDateTimeFormat]] internal slot and ? OrdinaryHasInstance(%DateTimeFormat%, \( dtf \)) is true, then
12 DisplayNames Objects

12.1 The Intl.DisplayNames Constructor

The DisplayNames constructor is the %DisplayNames% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

12.1.1 Intl.DisplayNames ( locales, options )

When the Intl.DisplayNames function is called with arguments locales and options, the following steps are taken:

1. If NewTarget is undefined, throw a TypeError exception.
2. Let displayNames be ? OrdinaryCreateFromConstructor(NewTarget, "%DisplayNames.prototype%", « [InitializedDisplayNames], [[Locale]], [[Style]], [[Type]], [[Fallback]], [[LanguageDisplay]], [[Fields]] »).
4. If options is undefined, throw a TypeError exception.
5. Set options to ? GetOptionsObject(options).
6. Let opt be a new Record.
7. Let localeData be %DisplayNames%.[[LocaleData]].
9. Set opt.[[localeMatcher]] to matcher.
10. Let r be ResolveLocale(%DisplayNames%.[[AvailableLocales]], requestedLocales, opt, %DisplayNames%. [[RelevantExtensionKeys]]).
12. Set displayNames.[[Style]] to style.
14. If type is undefined, throw a TypeError exception.
15. Set displayNames.[[Type]] to type.
17. Set displayNames.[[Fallback]] to fallback.
18. Set displayNames.[[Locale]] to r.[[locale]].
19. Let dataLocale be r.[[dataLocale]].
20. Let dataLocaleData be localeData.[[<dataLocale>]].
21. Let types be dataLocaleData.[[types]].
22. Assert: types is a Record (see 12.2.3).
24. Let typeFields be types.[[[type]]].
25. Assert: typeFields is a Record (see 12.2.3).
26. If \texttt{type} is "language", then
   a. Set \texttt{displayNames.[[LanguageDisplay]]} to \texttt{languageDisplay}.
   b. Let \texttt{typeFields} be \texttt{typeFields.[[\textless languageDisplay\textgreater ]]}.
   c. Assert: \texttt{typeFields} is a Record (see 12.2.3).
27. Let \texttt{styleFields} be \texttt{typeFields.[[\textless style\textgreater ]]}.
28. Assert: \texttt{styleFields} is a Record (see 12.2.3).
29. Set \texttt{displayNames.[[Fields]]} to \texttt{styleFields}.
30. Return \texttt{displayNames}.

12.2 Properties of the Intl.DisplayNames Constructor

The Intl.DisplayNames constructor has the following properties:

12.2.1 Intl.DisplayNames.prototype

The value of \texttt{Intl.DisplayNames.prototype} is \%DisplayNames.prototype\%
.
This property has the attributes \{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false \}.

12.2.2 Intl.DisplayNames.supportedLocalesOf (~locales [ , options ]~)

When the \texttt{supportedLocalesOf} method is called with arguments \texttt{locales} and \texttt{options}, the following steps are taken:

1. Let \texttt{availableLocales} be \%DisplayNames\%.[[AvailableLocales]]
2. Let \texttt{requestedLocales} be ? \texttt{CanonicalizeLocaleList(locales)}
3. Return ? \texttt{SupportedLocales(availableLocales, requestedLocales, options)}

12.2.3 Internal slots

The value of the [[AvailableLocales]] internal slot is implementation-defined within the constraints described in 9.1.
The value of the [[RelevantExtensionKeys]] internal slot is « ».
The value of the [[LocaleData]] internal slot is implementation-defined within the constraints described in 9.1 and the following additional constraints:

- [[LocaleData].[[\textless locale\textgreater ]]] must have a [[types]] field for all locale values \texttt{locale}. The value of this field must be a Record, which must have fields with the names of all display name types: "language", "region", "script", "currency", "calendar", and "dateTimeField".
- The value of the field "language" must be a Record which must have fields with the names of one of the valid language displays: "dialect" and "standard".
- The language display fields under display name type "language" should contain Records which must have fields with the names of one of the valid display name styles: "narrow", "short", and "long".
- The value of the fields "region", "script", "currency", "calendar", and "dateTimeField" must be Records, which must have fields with the names of all display name styles: "narrow", "short", and "long".
• The display name style fields under display name type "language" should contain Records with keys corresponding to language codes matching the `unicode_language_id` production. The value of these fields must be string values.
• The display name style fields under display name type "region" should contain Records with keys corresponding to region codes. The value of these fields must be string values.
• The display name style fields under display name type "script" should contain Records with keys corresponding to script codes. The value of these fields must be string values.
• The display name style fields under display name type "currency" should contain Records with keys corresponding to currency codes. The value of these fields must be string values.
• The display name style fields under display name type "calendar" should contain Records with keys corresponding to a String value with the `type` given in Unicode Technical Standard 35 for the calendar used for formatting. The value of these fields must be string values.
• The display name style fields under display name type "dateTimeField" should contain Records with keys corresponding to codes listed in Table 9. The value of these fields must be string values.

NOTE
It is recommended that implementations use the locale data provided by the Common Locale Data Repository (available at https://cldr.unicode.org/).

12.3  Properties of the Intl.DisplayNames Prototype Object

The Intl.DisplayNames prototype object is itself an ordinary object. `%DisplayNames.prototype%` is not an Intl.DisplayNames instance and does not have an `[[InitializedDisplayNames]]` internal slot or any of the other internal slots of Intl.DisplayNames instance objects.

12.3.1 Intl.DisplayNames.prototype.constructor

The initial value of `Intl.DisplayNames.prototype.constructor` is `%DisplayNames%`.

12.3.2 Intl.DisplayNames.prototype[@@toStringTag ]

The initial value of the @@toStringTag property is the String value "Intl.DisplayNames".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

12.3.3 Intl.DisplayNames.prototype.of ( code )

When the `Intl.DisplayNames.prototype.of` is called with an argument `code`, the following steps are taken:

1. Let `displayNames` be this value.
2. Perform ? `RequireInternalSlot`(`displayNames`, `[[InitializedDisplayNames]]`).
3. Let `code` be ? `ToString`(`code`).
4. Let `code` be ? `CanonicalCodeForDisplayNames`(`displayNames.[[Type]]`, `code`).
5. Let `fields` be `displayNames.[[Fields]]`.
6. If `fields` has a field `[[<code>]]`, return `fields.[[<code>]]`.
7. If `displayNames.[[Fallback]]` is "code", return `code`.
8. Return `undefined`.

© Ecma International
12.3.4 Intl.DisplayNames.prototype.resolvedOptions ( )

This function provides access to the locale and options computed during initialization of the object.

1. Let `displayNames` be `this` value.
2. Perform ? RequireInternalSlot(`displayNames`, `[[InitializedDisplayNames]]`).
3. Let `options` be ! OrdinaryObjectCreate( %Object.prototype% ).
4. For each row of Table 8, except the header row, in table order, do
   a. Let `p` be the Property value of the current row.
   b. Let `v` be the value of `displayNames`'s internal slot whose name is the Internal Slot value of the current row.
   c. Assert: `v` is not `undefined`.
   d. Perform ! CreateDataPropertyOrThrow(`options`, `p`, `v`).
5. Return `options`.

### Table 8: Resolved Options of DisplayNames Instances

<table>
<thead>
<tr>
<th>Internal Slot</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[[Locale]]</code></td>
<td>&quot;locale&quot;</td>
</tr>
<tr>
<td><code>[[Style]]</code></td>
<td>&quot;style&quot;</td>
</tr>
<tr>
<td><code>[[Type]]</code></td>
<td>&quot;type&quot;</td>
</tr>
<tr>
<td><code>[[Fallback]]</code></td>
<td>&quot;fallback&quot;</td>
</tr>
<tr>
<td><code>[[LanguageDisplay]]</code></td>
<td>&quot;languageDisplay&quot;</td>
</tr>
</tbody>
</table>

12.4 Properties of Intl.DisplayNames Instances

Intl.DisplayNames instances are ordinary objects that inherit properties from %DisplayNames.prototype%. Intl.DisplayNames instances have an `[[InitializedDisplayNames]]` internal slot.

Intl.DisplayNames instances also have several internal slots that are computed by the constructor:

- `[[Locale]]` is a String value with the language tag of the locale whose localization is used for formatting.
- `[[Style]]` is one of the String values "narrow", "short", or "long", identifying the display name style used.
- `[[Type]]` is one of the String values "language", "region", "script", "currency", "calendar", or "dateTimeField", identifying the type of the display names requested.
- `[[Fallback]]` is one of the String values "code" or "none", identifying the fallback return when the system does not have the requested display name.
- `[[LanguageDisplay]]` is one of the String values "dialect" or "standard", identifying the language display kind. It is only used when `[[Type]]` has the value "language".
- `[[Fields]]` is a Record (see 12.2.3) which must have fields with keys corresponding to codes according to `[[Style]]`, `[[Type]]`, and `[[LanguageDisplay]]`.

12.5 Abstract Operations for DisplayNames Objects
12.5.1 CanonicalCodeForDisplayNames (type, code)

The CanonicalCodeForDisplayNames abstract operation takes arguments type (a String) and code (a String). It verifies that the code argument represents a well-formed code according to the type argument and returns the case-regularized form of the code. The algorithm refers to UTS 35's Unicode Language and Locale Identifiers grammar. The following steps are taken:

1. If type is "language", then
   a. If code does not match the unicode_language_id production, throw a RangeError exception.
   b. If !IsStructurallyValidLanguageTag(code) is false, throw a RangeError exception.
   c. Return !CanonicalizeUnicodeLocaleId(code).
2. If type is "region", then
   a. If code does not match the unicode_region_subtag production, throw a RangeError exception.
   b. Return the ASCII-uppercase of code.
3. If type is "script", then
   a. If code does not match the unicode_script_subtag production, throw a RangeError exception.
   b. Assert: The length of code is 4, and every code unit of code represents an ASCII letter (0x0041 through 0x005A and 0x0061 through 0x007A, both inclusive).
   c. Let first be the ASCII-uppercase of the substring of code from 0 to 1.
   d. Let rest be the ASCII-lowercase of the substring of code from 1.
   e. Return the string-concatenation of first and rest.
4. If type is "calendar", then
   a. If code does not match the Unicode Locale Identifier type nonterminal, throw a RangeError exception.
   b. If code uses any of the backwards compatibility syntax described in Unicode Technical Standard #35 LDML § 3.3 BCP 47 Conformance, throw a RangeError exception.
   c. Return the ASCII-lowercase of code.
5. If type is "dateTimeField", then
   a. If the result of IsValidDateTimeFieldCode(code) is false, throw a RangeError exception.
   b. Return code.
6. Assert: type is "currency".
7. If !IsWellFormedCurrencyCode(code) is false, throw a RangeError exception.
8. Return the ASCII-uppercase of code.

12.5.2 IsValidDateTimeFieldCode (field)

The abstract operation IsValidDateTimeFieldCode takes argument field (a String). It verifies that the field argument represents a valid date time field code. It performs the following steps when called:

1. If field is listed in the Code column of Table 9, return true.
2. Return false.

Table 9: Codes For Date Time Field of DisplayNames

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;era&quot;</td>
<td>The field indicating the era, e.g. AD or BC in the Gregorian or Julian calendar.</td>
</tr>
<tr>
<td>&quot;year&quot;</td>
<td>The field indicating the year (within an era).</td>
</tr>
<tr>
<td>&quot;quarter&quot;</td>
<td>The field indicating the quarter, e.g. Q2, 2nd quarter, etc.</td>
</tr>
</tbody>
</table>
13 ListFormat Objects

13.1 The Intl.ListFormat Constructor

The ListFormat constructor is the %ListFormat% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

13.1.1 Intl.ListFormat ([ locales [, options ] ])

When the Intl.ListFormat function is called with optional arguments locales and options, the following steps are taken:

1. If NewTarget is undefined, throw a TypeError exception.
2. Let listFormat be ? OrdinaryCreateFromConstructor(NewTarget, "%ListFormat.prototype%, "
   [[InitializedListFormat]], [[Locale]], [[Type]], [[Style]], [[Templates]] »).
4. Set options to ? GetOptionsObject(options).
5. Let opt be a new Record.
7. Set opt.[[localeMatcher]] to matcher.
8. Let localeData be %ListFormat%.[[LocaleData]].
9. Let r be ResolveLocale(%ListFormat%.[[AvailableLocales]], requestedLocales, opt, %ListFormat%.
   [[RelevantExtensionKeys]], localeData).
10. Set listFormat.[[Locale]] to r.[[locale]].
11. Let type be ? GetOption(options, "type", "string", « "conjunction", "disjunction", "unit" », "conjunction").
12. Set listFormat.[[Type]] to type.
14. Set listFormat.[[Style]] to style.
15. Let `dataLocale` be \( r.[[dataLocale]] \).
16. Let `dataLocaleData` be `localeData.[[<dataLocale>]]`.
17. Let `dataLocaleTypes` be `dataLocaleData.[[<type>]]`.
18. Set `listFormat.[[Templates]]` to `dataLocaleTypes.[[<style>]]`.
19. Return `listFormat`.

### 13.2 Properties of the Intl.ListFormat Constructor

The Intl.ListFormat constructor has the following properties:

#### 13.2.1 Intl.ListFormat.prototype

The value of `Intl.ListFormat.prototype` is `%ListFormat.prototype%`.

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

#### 13.2.2 Intl.ListFormat.supportedLocalesOf ( locales [, options ] )

When the `supportedLocalesOf` method is called with arguments `locales` and `options`, the following steps are taken:

1. Let `availableLocales` be `%ListFormat%.[[AvailableLocales]]`.
2. Let `requestedLocales` be `? CanonicalizeLocaleList(locales)`.

### 13.2.3 Internal slots

The value of the [[AvailableLocales]] internal slot is implementation-defined within the constraints described in 9.1.

The value of the [[RelevantExtensionKeys]] internal slot is « ».

**NOTE 1** Intl.ListFormat does not have any relevant extension keys.

The value of the [[LocaleData]] internal slot is implementation-defined within the constraints described in 9.1 and the following additional constraints, for each locale value `locale` in `%ListFormat%.[[AvailableLocales]]`:

- `[[LocaleData]].[[<locale>]]` is a Record which has three fields `[[conjunction]]`, `[[disjunction]]`, and `[[unit]]`. Each of these is a Record which must have fields with the names of three formatting styles: `[[long]]`, `[[short]]`, and `[[narrow]]`.
- Each of those fields is considered a ListFormat template set, which must be a List of Records with fields named: `[[Pair]]`, `[[Start]]`, `[[Middle]]`, and `[[End]]`. Each of those fields must be a template string as specified in LDML List Format Rules. Each template string must contain the substrings "\(0\)" and "\(1\)" exactly once. The substring "\(0\)" should occur before the substring "\(1\)".

**NOTE 2** It is recommended that implementations use the locale data provided by the Common Locale Data Repository (available at https://cldr.unicode.org/). In LDML's listPattern, `conjunction` corresponds to "standard", `disjunction` corresponds to "or", and `unit` corresponds to "unit".

© Ecma International
NOTE 3  Among the list types, **conjunction** stands for "and"-based lists (e.g., "A, B, and C"), **disjunction** stands for "or"-based lists (e.g., "A, B, or C"), and **unit** stands for lists of values with units (e.g., "5 pounds, 12 ounces").

### 13.3 Properties of the Intl.ListFormat Prototype Object

The Intl.ListFormat prototype object is itself an ordinary object. `%ListFormat.prototype%` is not an Intl.ListFormat instance and does not have an `[[InitializedListFormat]]` internal slot or any of the other internal slots of Intl.ListFormat instance objects.

#### 13.3.1 Intl.ListFormat.prototype.constructor

The initial value of `Intl.ListFormat.prototype.constructor` is `%ListFormat%`.

#### 13.3.2 Intl.ListFormat.prototype[ @@toStringTag ]

The initial value of the `@@toStringTag` property is the String value "Intl.ListFormat".

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

#### 13.3.3 Intl.ListFormat.prototype.format ( list )

When the `format` method is called with an argument `list`, the following steps are taken:

1. Let `lf` be the `this` value.
3. Let `stringList` be ? StringListFromIterable(`list`).

#### 13.3.4 Intl.ListFormat.prototype.formatToParts ( list )

When the `formatToParts` method is called with an argument `list`, the following steps are taken:

1. Let `lf` be the `this` value.
3. Let `stringList` be ? StringListFromIterable(`list`).
4. Return ! FormatListToParts(`lf`, `stringList`).

#### 13.3.5 Intl.ListFormat.prototype.resolvedOptions ()

This function provides access to the locale and options computed during initialization of the object.

1. Let `lf` be the `this` value.
3. Let `options` be ! OrdinaryObjectCreate(%Object.prototype%).
4. For each row of Table 10, except the header row, in table order, do
a. Let \( p \) be the Property value of the current row.

b. Let \( v \) be the value of \( l \)'s internal slot whose name is the Internal Slot value of the current row.

c. Assert: \( v \) is not undefined.

d. Perform ! CreateDataPropertyOrThrow(\( options, p, v \)).

5. Return \( options \).

Table 10: Resolved Options of ListFormat Instances

<table>
<thead>
<tr>
<th>Internal Slot</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Locale]]</td>
<td>&quot;locale&quot;</td>
</tr>
<tr>
<td>[[Type]]</td>
<td>&quot;type&quot;</td>
</tr>
<tr>
<td>[[Style]]</td>
<td>&quot;style&quot;</td>
</tr>
</tbody>
</table>

13.4 Properties of Intl.ListFormat Instances

Intl.ListFormat instances inherit properties from %ListFormat.prototype%.

Intl.ListFormat instances have an [[InitializedListFormat]] internal slot.

Intl.ListFormat instances also have several internal slots that are computed by the constructor:

- [[Locale]] is a String value with the language tag of the locale whose localization is used by the list format styles.
- [[Type]] is one of the String values "conjunction", "disjunction", or "unit", identifying the list of types used.
- [[Style]] is one of the String values "long", "short", or "narrow", identifying the list formatting style used.
- [[Templates]] is a ListFormat template set.

13.5 Abstract Operations for ListFormat Objects

13.5.1 DeconstructPattern ( \( pattern, placeables \) )

The DeconstructPattern abstract operation is called with arguments \( pattern \) (which must be a String) and \( placeables \) (which must be a Record), and deconstructs the pattern string into a list of parts.

The placeables record is a record whose keys are placeables tokens used in the pattern string, and values are parts records which will be used in the result List to represent the token part. Example:

Input:

DeconstructPattern("AA{xx}BB{yy}CC", {
  [[xx]]: {{[Type]]: "hour", [[Value]]: "15"},
  [[yy]]: {{[Type]]: "minute", [[Value]]: "06"}
})

Output (List of parts records):

`{[[Type]]: "literal", [[Value]]: "AA"},`
1. Let $patternParts$ be $\text{PartitionPattern}(pattern)$.
2. Let $result$ be a new empty List.
3. For each Record $\{ \{\text{Type}\}, \{\text{Value}\} \} \, patternPart$ of $patternParts$, do
   a. Let $part$ be $patternPart.\{\text{Type}\}$.
   b. If $part$ is "literal", then
      i. Append Record $\{ \{\text{Type}\}: \text{"literal"}, \{\text{Value}\}: patternPart.\{\text{Value}\} \} \, \text{to} \, result$.
   c. Else,
      i. Assert: $placeables$ has a field $[<part>]$.
      ii. Let $subst$ be $placeables.[<part>]$.
      iii. If Type($subst$) is List, then
         1. For each element $s$ of $subst$, do
            a. Append $s$ to $result$.
      iv. Else,
         1. Append $subst$ to $result$.
4. Return $result$.

13.5.2 CreatePartsFromList ($listFormat$, $list$)

The CreatePartsFromList abstract operation is called with arguments $listFormat$ (which must be an object initialized as a ListFormat) and $list$ (which must be a List of String values), and creates the corresponding list of parts according to the effective locale and the formatting options of $listFormat$. Each part is a Record with two fields: $\{\text{Type}\}$, which must be a string with values "element" or "literal", and $\{\text{Value}\}$ which must be a string or a number. The following steps are taken:

1. Let $size$ be the number of elements of $list$.
2. If $size$ is 0, then
   a. Return a new empty List.
3. If $size$ is 2, then
   a. Let $n$ be an index into $listFormat.\{\text{Templates}\}$ based on $listFormat.\{\text{Locale}\}$, $list[0]$, and $list[1]$.
   b. Let $pattern$ be $listFormat.\{\text{Templates}\}[n].\{\text{Pair}\}$.
   c. Let $first$ be a new Record $\{ \{\text{Type}\}: \text{"element"}, \{\text{Value}\}: list[0] \} \,$.
   d. Let $second$ be a new Record $\{ \{\text{Type}\}: \text{"element"}, \{\text{Value}\}: list[1] \}$.
   e. Let $placeables$ be a new Record $\{ [0]: first, [1]: second \}$.
   f. Return $! \text{DeconstructPattern}(pattern, placeables)$.
4. Let $last$ be a new Record $\{ \{\text{Type}\}: \text{"element"}, \{\text{Value}\}: list[size - 1] \}$.
5. Let $parts$ be « $last$ ».
7. Repeat, while $i \geq 0$,
   a. Let $head$ be a new Record $\{ \{\text{Type}\}: \text{"element"}, \{\text{Value}\}: list[i] \}$.
   b. Let $n$ be an implementation-defined index into $listFormat.\{\text{Templates}\}$ based on $listFormat.\{\text{Locale}\}$, $head$, and $parts$. 
c. If \( i \) is 0, then
   i. Let \( \text{pattern} \) be \( \text{listFormat}[[\text{Templates}}][[n]].[[\text{Start}}].

d. Else if \( i \) is less than \( \text{size} - 2 \), then
   i. Let \( \text{pattern} \) be \( \text{listFormat}[[\text{Templates}}][[n]].[[\text{Middle}}].

e. Else,
   i. Let \( \text{pattern} \) be \( \text{listFormat}[[\text{Templates}}][[n]].[[\text{End}}].

f. Let \( \text{placeables} \) be a new Record \{ [[0]]: \text{head}, [[1]]: \text{parts} \}.

g. Set \( \text{parts} \) to ! \text{DeconstructPattern}(\text{pattern}, \text{placeables}).
h. Decrement \( i \) by 1.

8. Return \( \text{parts} \).

NOTE The index \( n \) to select across multiple templates permits the conjunction to be dependent on the context, as in Spanish, where either "y" or "e" may be selected, depending on the following word.

13.5.3 FormatList ( \( \text{listFormat}, \text{list} \) )

The FormatList abstract operation is called with arguments \( \text{listFormat} \) (which must be an object initialized as a ListFormat) and \( \text{list} \) (which must be a List of String values), and performs the following steps:

1. Let \( \text{parts} \) be ! \text{CreatePartsFromList}(\text{listFormat}, \text{list}).
2. Let \( \text{result} \) be an empty String.
3. For each Record \{ [[\text{Type}}], [[\text{Value}}] \} \text{part} in \text{parts}, do
   a. Set \( \text{result} \) to the string-concatenation of \( \text{result} \) and \( \text{part}[[\text{Value}}].
4. Return \( \text{result} \).

13.5.4 FormatListToParts ( \( \text{listFormat}, \text{list} \) )

The FormatListToParts abstract operation is called with arguments \( \text{listFormat} \) (which must be an object initialized as a ListFormat) and \( \text{list} \) (which must be a List of String values), and performs the following steps:

1. Let \( \text{parts} \) be ! \text{CreatePartsFromList}(\text{listFormat}, \text{list}).
2. Let \( \text{result} \) be ! \text{ArrayCreate}(0).
3. Let \( n \) be 0.
4. For each Record \{ [[\text{Type}}], [[\text{Value}}] \} \text{part} in \text{parts}, do
   a. Let \( O \) be ! \text{OrdinaryObjectCreate}(%\text{Object.prototype}%).
   b. Perform ! \text{CreateDataPropertyOrThrow}(O, "\text{type}", \text{part}[[\text{Type}}]).
   c. Perform ! \text{CreateDataPropertyOrThrow}(O, "\text{value}", \text{part}[[\text{Value}}]).
   d. Perform ! \text{CreateDataPropertyOrThrow}(\text{result}, ! \text{ToString}(n), O).
   e. Increment \( n \) by 1.
5. Return \( \text{result} \).

13.5.5 StringListFromIterable ( \( \text{iterable} \) )

The abstract operation StringListFromIterable performs the following steps:

1. If \( \text{iterable} \) is \text{undefined}, then
   a. Return a new empty List.
2. Let \( \text{iteratorRecord} \) be ? \text{GetIterator}(\text{iterable}).
3. Let list be a new empty List.
4. Let next be true.
5. Repeat, while next is not false,
   a. Set next to ? IteratorStep(iteratorRecord).
   b. If next is not false, then
      i. Let nextValue be ? IteratorValue(next).
      ii. If Type(nextValue) is not String, then
          1. Let error be ThrowCompletion(a newly created TypeError object).
      iii. Append nextValue to the end of the List list.
6. Return list.

NOTE This algorithm raises exceptions when it encounters values that are not Strings, because there is no obvious locale-aware coercion for arbitrary values.

14 Locale Objects

14.1 The Intl.Locale Constructor

The Locale constructor is the %Locale% intrinsic object and a standard built-in property of the Intl object.

14.1.1 Intl.Locale (tag [, options ])

The following algorithm refers to the type nonterminal from UTS 35’s Unicode Locale Identifier grammar. When the Intl.Locale function is called with an argument tag and an optional argument options, the following steps are taken:

1. If NewTarget is undefined, throw a TypeError exception.
2. Let relevantExtensionKeys be %Locale%.[[RelevantExtensionKeys]].
3. Let internalSlotsList be « [[InitializedLocale]], [[Locale]], [[Calendar]], [[Collation]], [[HourCycle]], [[NumberingSystem]] ».
4. If relevantExtensionKeys contains "kf", then
   a. Append [[CaseFirst]] as the last element of internalSlotsList.
5. If relevantExtensionKeys contains "kn", then
   a. Append [[Numeric]] as the last element of internalSlotsList.
7. If Type(tag) is not String or Object, throw a TypeError exception.
8. If Type(tag) is Object and tag has an [[InitializedLocale]] internal slot, then
   a. Let tag be tag.[[Locale]].
9. Else,
   a. Let tag be ? ToString(tag).
10. Set options to ? CoerceOptionsToObject(options).
11. Set tag to ? ApplyOptionsToTag(tag, options).
12. Let opt be a new Record.
14. If calendar is not undefined, then
   a. If calendar does not match the Unicode Locale Identifier type nonterminal, throw a RangeError exception.
15. Set opt.[[ca]] to calendar.
17. If collation is not undefined, then
   a. If collation does not match the Unicode Locale Identifier type nonterminal, throw a RangeError exception.
18. Set opt.[[co]] to collation.
20. Set opt.[[hc]] to hc.
22. Set opt.[[kf]] to kf.
24. If kn is not undefined, set kn to ! ToString(kn).
25. Set opt.[[kn]] to kn.
27. If numberingSystem is not undefined, then
   a. If numberingSystem does not match the Unicode Locale Identifier type nonterminal, throw a RangeError exception.
28. Set opt.[[nu]] to numberingSystem.
29. Let r be ! ApplyUnicodeExtensionToTag(tag, opt, relevantExtensionKeys).
30. Set locale.[[Locale]] to r.[[locale]].
31. Set locale.[[Calendar]] to r.[[ca]].
32. Set locale.[[Collation]] to r.[[co]].
33. Set locale.[[HourCycle]] to r.[[hc]].
34. If relevantExtensionKeys contains "kf", then
   a. Set locale.[[CaseFirst]] to r.[[kf]].
35. If relevantExtensionKeys contains "kn", then
   a. If ! SameValue(r.[[kn]], "true") is true or r.[[kn]] is the empty String, then
      i. Set locale.[[Numeric]] to true.
   b. Else,
      i. Set locale.[[Numeric]] to false.
36. Set locale.[[NumberingSystem]] to r.[[nu]].
37. Return locale.

14.1.2 ApplyOptionsToTag ( tag, options )

The following algorithm refers to UTS 35's Unicode Language and Locale Identifiers grammar.

1. Assert: Type(tag) is String.
2. Assert: Type(options) is Object.
3. If ! IsStructurallyValidLanguageTag(tag) is false, throw a RangeError exception.
5. If language is not undefined, then
   a. If language does not match the unicode_language_subtag production, throw a RangeError exception.

© Ecma International
7. If `script` is not `undefined`, then
   a. If `script` does not match the `unicode_script_subtag` production, throw a `RangeError` exception.
9. If `region` is not `undefined`, then
   a. If `region` does not match the `unicode_region_subtag` production, throw a `RangeError` exception.
10. Set `tag` to `! CanonicalizeUnicodeLocaleId(tag)`.
11. Assert: `tag` matches the `unicode_locale_id` production.
12. Let `languageId` be the substring of `tag` corresponding to the `unicode_language_id` production.
13. If `language` is not `undefined`, then
    a. Set `languageId` to `languageId` with the substring corresponding to the `unicode_language_subtag` production replaced by the string `language`.
14. If `script` is not `undefined`, then
    a. If `languageId` does not contain a `unicode_script_subtag` production, then
       i. Set `languageId` to the string-concatenation of the `unicode_language_subtag` production of `languageId`, `"-", script`, and the rest of `languageId`.
    b. Else,
       i. Set `languageId` to `languageId` with the substring corresponding to the `unicode_script_subtag` production replaced by the string `script`.
15. If `region` is not `undefined`, then
    a. If `languageId` does not contain a `unicode_region_subtag` production, then
       i. Set `languageId` to the string-concatenation of the `unicode_language_subtag` production of `languageId`, the substring corresponding to "-" and the `unicode_script_subtag` production if present, "-", `region`, and the rest of `languageId`.
    b. Else,
       i. Set `languageId` to `languageId` with the substring corresponding to the `unicode_region_subtag` production replaced by the string `region`.
16. Set `tag` to `tag` with the substring corresponding to the `unicode_language_id` production replaced by the string `languageId`.
17. Return `! CanonicalizeUnicodeLocaleId(tag)`.

### 14.1.3 ApplyUnicodeExtensionToTag (`tag, options, relevantExtensionKeys`)`

The following algorithm refers to UTS 35's Unicode Language and Locale Identifiers grammar.

1. Assert: `Type(tag)` is String.
2. Assert: `tag` matches the `unicode_locale_id` production.
3. If `tag` contains a substring that is a Unicode locale extension sequence, then
   a. Let `extension` be the String value consisting of the substring of the Unicode locale extension sequence within `tag`.
   b. Let `components` be `! UnicodeExtensionComponents(extension)`.
   c. Let `attributes` be `components`.[[Attributes]].
   d. Let `keywords` be `components`.[[Keywords]].
4. Else,
   a. Let `attributes` be a new empty List.
   b. Let `keywords` be a new empty List.
5. Let `result` be a new Record.
6. For each element `key` of `relevantExtensionKeys`, do
a. Let \textit{value} be \textit{undefined}.

b. If \textit{keywords} contains an element whose [[Key]] is the same as \textit{key}, then
   i. Let \textit{entry} be the element of \textit{keywords} whose [[Key]] is the same as \textit{key}.
   ii. Let \textit{value} be \textit{entry}.[[Value]].

c. Else,
   i. Let \textit{entry} be \textit{empty}.

d. \textbf{Assert: options} has a field \textit{[[<key>]]}.

e. Let \textit{optionsValue} be \textit{options}.[[<key>]].

f. If \textit{optionsValue} is not \textit{undefined}, then
   i. \textbf{Assert:} \textbf{Type} (\textit{optionsValue}) is \textbf{String}.
   ii. Let \textit{value} be \textit{optionsValue}.
   iii. If \textit{entry} is not \textit{empty}, then
       1. Set \textit{entry}.[[Value]] to \textit{value}.
   iv. Else,
       1. Append the Record \{ [[Key]]: \textit{key}, [[Value]]: \textit{value} \} to \textit{keywords}.

g. Set \textit{result}.[[<key>]] to \textit{value}.

7. Let \textit{locale} be the String value that is \textit{tag} with any Unicode locale extension sequences removed.

8. Let \textit{newExtension} be a Unicode BCP 47 U Extension based on \textit{attributes} and \textit{keywords}.

9. If \textit{newExtension} is not the empty String, then
   a. Let \textit{locale} be \textbf{InsertUnicodeExtensionAndCanonicalize} (\textit{locale}, \textit{newExtension}).

10. Set \textit{result}.[[locale]] to \textit{locale}.

11. Return \textit{result}.

\section*{14.2 Properties of the Intl.Locale Constructor}

The Intl.Locale \textit{constructor} has the following properties:

\subsection*{14.2.1 Intl.Locale.prototype}

The value of \texttt{Intl.Locale.prototype} is \texttt{%Locale.prototype\%}.

This property has the attributes \{ [[Writable]]: \textit{false}, [[Enumerable]]: \textit{false}, [[Configurable]]: \textit{false} \}.

\subsection*{14.2.2 Internal slots}

The value of the [[\textit{relevantExtensionKeys}]] internal slot is « "ca", "co", "hc", "kf", "kn", "nu" ». If \texttt{%Collator\%.[[\textit{relevantExtensionKeys}]]} does not contain "kf", then remove "kf" from \texttt{%Locale\%.[[\textit{relevantExtensionKeys}]]}.

If \texttt{%Collator\%.[[\textit{relevantExtensionKeys}]]} does not contain "kn", then remove "kn" from \texttt{%Locale\%.[[\textit{relevantExtensionKeys}]]}.

\section*{14.3 Properties of the Intl.Locale Prototype Object}

The Intl.Locale prototype object is itself an ordinary object. \texttt{%Locale.prototype\%} is not an Intl.Locale instance and does not have an [[\textit{initializedLocale}]] internal slot or any of the other internal slots of Intl.Locale instance objects.
14.3.1 Intl.Locale.prototype.constructor

The initial value of `Intl.Locale.prototype.constructor` is `%Locale%`.

14.3.2 Intl.Locale.prototype[ @@toStringTag ]

The initial value of the @@toStringTag property is the String value "Intl.Locale".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

14.3.3 Intl.Locale.prototype.maximize ()

1. Let loc be the this value.
2. Perform ? RequireInternalSlot(loc, [[InitializedLocale]]).
3. Let maximal be the result of the Add Likely Subtags algorithm applied to loc.[[Locale]]. If an error is signaled, set maximal to loc.[[Locale]].
4. Return ! Construct(%Locale%, maximal).

14.3.4 Intl.Locale.prototype.minimize ()

1. Let loc be the this value.
2. Perform ? RequireInternalSlot(loc, [[InitializedLocale]]).
3. Let minimal be the result of the Remove Likely Subtags algorithm applied to loc.[[Locale]]. If an error is signaled, set minimal to loc.[[Locale]].
4. Return ! Construct(%Locale%, minimal).

14.3.5 Intl.Locale.prototype.toString ()

1. Let loc be the this value.
2. Perform ? RequireInternalSlot(loc, [[InitializedLocale]]).
3. Return loc.[[Locale]].

14.3.6 get Intl.Locale.prototype.baseName

`Intl.Locale.prototype.baseName` is an accessor property whose set accessor function is undefined. The following algorithm refers to UTS 35’s Unicode Language and Locale Identifiers grammar. Its get accessor function performs the following steps:

1. Let loc be the this value.
2. Perform ? RequireInternalSlot(loc, [[InitializedLocale]]).
3. Let locale be loc.[[Locale]].
4. Return the substring of locale corresponding to the `unicode_language_id` production.

14.3.7 get Intl.Locale.prototype.calendar

`Intl.Locale.prototype.calendar` is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:
1. Let \( loc \) be the this value.
2. Perform \( \text{RequireInternalSlot}(loc, [[\text{InitializedLocale}]]) \).
3. Return \( loc.[[\text{Calendar}]] \).

### 14.3.8 get Intl.Locale.prototype.caseFirst

This property only exists if \( \%\text{Locale}\%.[[\text{RelevantExtensionKeys}]] \) contains "kf".

\( \text{Intl.Locale.prototype.caseFirst} \) is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let \( loc \) be the this value.
2. Perform \( \text{RequireInternalSlot}(loc, [[\text{InitializedLocale}]]) \).
3. Return \( loc.[[\text{CaseFirst}]] \).

### 14.3.9 get Intl.Locale.prototype.collation

\( \text{Intl.Locale.prototype.collation} \) is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let \( loc \) be the this value.
2. Perform \( \text{RequireInternalSlot}(loc, [[\text{InitializedLocale}]]) \).
3. Return \( loc.[[\text{Collation}]] \).

### 14.3.10 get Intl.Locale.prototype.hourCycle

\( \text{Intl.Locale.prototype.hourCycle} \) is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let \( loc \) be the this value.
2. Perform \( \text{RequireInternalSlot}(loc, [[\text{InitializedLocale}]]) \).
3. Return \( loc.[[\text{HourCycle}]] \).

### 14.3.11 get Intl.Locale.prototype.numeric

This property only exists if \( \%\text{Locale}\%.[[\text{RelevantExtensionKeys}]] \) contains "kn".

\( \text{Intl.Locale.prototype.numeric} \) is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let \( loc \) be the this value.
2. Perform \( \text{RequireInternalSlot}(loc, [[\text{InitializedLocale}]]) \).
3. Return \( loc.[[\text{Numeric}]] \).

### 14.3.12 get Intl.Locale.prototype.numberingSystem

\( \text{Intl.Locale.prototype.numberingSystem} \) is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:
1. Let `loc` be the this value.
2. Perform ? `RequireInternalSlot(loc, [[InitializedLocale]])`.
3. Return `loc.([NumberingSystem])`.

14.3.13  get Intl.Locale.prototype.language

`Intl.Locale.prototype.language` is an accessor property whose set accessor function is `undefined`. The following algorithm refers to UTS 35's Unicode Language and Locale Identifiers grammar. Its get accessor function performs the following steps:

1. Let `loc` be the this value.
2. Perform ? `RequireInternalSlot(loc, [[InitializedLocale]])`.
3. Let `locale` be `loc.([Locale])`.
4. Assert: `locale` matches the `unicode_locale_id` production.
5. Return the substring of `locale` corresponding to the `unicode_language_subtag` production of the `unicode_language_id`.

14.3.14  get Intl.Locale.prototype.script

`Intl.Locale.prototype.script` is an accessor property whose set accessor function is `undefined`. The following algorithm refers to UTS 35's Unicode Language and Locale Identifiers grammar. Its get accessor function performs the following steps:

1. Let `loc` be the this value.
2. Perform ? `RequireInternalSlot(loc, [[InitializedLocale]])`.
3. Let `locale` be `loc.([Locale])`.
4. Assert: `locale` matches the `unicode_locale_id` production.
5. If the `unicode_language_id` production of `locale` does not contain the `"-" unicode_script_subtag` sequence, return `undefined`.
6. Return the substring of `locale` corresponding to the `unicode_script_subtag` production of the `unicode_language_id`.

14.3.15  get Intl.Locale.prototype.region

`Intl.Locale.prototype.region` is an accessor property whose set accessor function is `undefined`. The following algorithm refers to UTS 35's Unicode Language and Locale Identifiers grammar. Its get accessor function performs the following steps:

1. Let `loc` be the this value.
2. Perform ? `RequireInternalSlot(loc, [[InitializedLocale]])`.
3. Let `locale` be `loc.([Locale])`.
4. Assert: `locale` matches the `unicode_locale_id` production.
5. If the `unicode_language_id` production of `locale` does not contain the `"-" unicode_region_subtag` sequence, return `undefined`.
6. Return the substring of `locale` corresponding to the `unicode_region_subtag` production of the `unicode_language_id`.
15 NumberFormat Objects

15.1 The Intl.NumberFormat Constructor

The NumberFormat constructor is the %NumberFormat% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

15.1.1 Intl.NumberFormat ([ locales [, options ] ])

When the Intl.NumberFormat function is called with optional arguments locales and options, the following steps are taken:

1. If NewTarget is undefined, let newTarget be the active function object, else let newTarget be NewTarget.
2. Let numberFormat be ? OrdinaryCreateFromConstructor(newTarget, "%NumberFormat.prototype%", « [InitializedNumberFormat], [Locale], [DataLocale], [NumberingSystem], [Style], [Unit], [UnitDisplay], [Currency], [CurrencyDisplay], [CurrencySign], [MinimumIntegerDigits], [MinimumFractionDigits], [MaximumFractionDigits], [MinimumSignificantDigits], [MaximumSignificantDigits], [RoundingType], [Notation], [CompactDisplay], [UseGrouping], [SignDisplay], [BoundFormat] »).
4. If the implementation supports the normative optional constructor mode of 4.3 Note 1, then
   a. Let this be the this value.
   b. Return ? ChainNumberFormat(numberFormat, NewTarget, this).
5. Return numberFormat.

NORMATIVE OPTIONAL

15.1.1.1 ChainNumberFormat ( numberFormat, newTarget, this )

1. If newTarget is undefined and ? OrdinaryHasInstance(%NumberFormat%, this) is true, then
   a. Perform ? DefinePropertyOrThrow(this, %Intl%.[FallbackSymbol]), PropertyDescriptor{ [[Value]: numberFormat, [[Writable]: false, [[Enumerable]: false, [[Configurable]: false]}.)
   b. Return this.
2. Return numberFormat.

15.1.2 InitializeNumberFormat ( numberFormat, locales, options )

The abstract operation InitializeNumberFormat accepts the arguments numberFormat (which must be an object), locales, and options. It initializes numberFormat as a NumberFormat object. The following steps are taken:

The following algorithm refers to the type nonterminal from UTS 35’s Unicode Locale Identifier grammar.

1. Let requestedLocales be ? CanonicalizeLocaleList(locales).
2. Set options to ? CoerceOptionsToObject(options).
3. Let opt be a new Record.
5. Set `opt.[localeMatcher]` to `matcher`.
7. If `numberingSystem` is not `undefined`, then
   a. If `numberingSystem` does not match the Unicode Locale Identifier type nonterminal, throw a `RangeError` exception.
8. Let `options.[null]` to `numberingSystem`.
9. Let `localeData` be `%NumberFormat%.[LocaleData]`.
10. Let `r` be `ResolveLocale(%NumberFormat%.[AvailableLocales], requestedLocales, opt, %NumberFormat%.[RelevantExtensionKeys], localeData).
14. Perform ? `SetNumberFormatUnitOptions(numberFormat, options)`.
15. Let `style` be `numberFormat.[Style]`.
16. If `style` is "currency", then
   a. Let `currency` be `numberFormat.[Currency]`.
   b. Let `cDigits` be `CurrencyDigits(currency)`.
   c. Let `mnfdDefault` be `cDigits`.
   d. Let `mxfdDefault` be `cDigits`.
17. Else,
   a. Let `mnfdDefault` be 0.
   b. If `style` is "percent", then
      i. Let `mxfdDefault` be 0.
   c. Else,
      i. Let `mxfdDefault` be 3.
19. Set `numberFormat.[Notation]` to `notation`.
20. Perform ? `SetNumberFormatDigitOptions(numberFormat, options, mnfdDefault, mxfdDefault, notation)`.
22. If `notation` is "compact", then
   a. Set `numberFormat.[CompactDisplay]` to `compactDisplay`.
27. Return `numberFormat`.

15.1.3 SetNumberFormatDigitOptions ( `intlObj`, `options`, `mnfdDefault`, `mxfdDefault`, `notation` )

The abstract operation SetNumberFormatDigitOptions takes arguments `intlObj` (an Object), `options` (an Object), `mnfdDefault` (a Number), `mxfdDefault` (a Number), and `notation` (a String). It populates the internal slots of `intlObj` that affect locale-independent number rounding (see 15.5.3). It performs the following steps when called:

1. Let `mnid` be ? `GetNumberOption(options, "minimumIntegerDigits", 1, 21, 1)`.
2. Let $mnfd$ be ? $\text{Get}(\text{options}, "\text{minimumFractionDigits}").$
3. Let $mxfd$ be ? $\text{Get}(\text{options}, "\text{maximumFractionDigits}").$
4. Let $mnsd$ be ? $\text{Get}(\text{options}, "\text{minimumSignificantDigits}").$
5. Let $mxsd$ be ? $\text{Get}(\text{options}, "\text{maximumSignificantDigits}").$
6. Set $\text{intlObj}.[[\text{MinimumIntegerDigits}]]$ to $mnid$.
7. If $mnsd$ is not $\text{undefined}$ or $mxsd$ is not $\text{undefined}$, then
   a. Let $hasSd$ be $\text{true}$.
8. Else,
   a. Let $hasSd$ be $\text{false}$.
9. If $mnfd$ is not $\text{undefined}$ or $mxfd$ is not $\text{undefined}$, then
   a. Let $hasFd$ be $\text{true}$.
10. Else,
    a. Let $hasFd$ be $\text{false}$.
11. Let $needSd$ be $\text{hasSd}$.
12. If $hasSd$ is $\text{true}$, or $hasFd$ is $\text{false}$ and $\text{notation}$ is "compact", then
    a. Let $needFd$ be $\text{false}$.
13. Else,
    a. Let $needFd$ be $\text{true}$.
14. If $needSd$ is $\text{true}$, then
    a. Assert: $hasSd$ is $\text{true}$.
    b. Set $mnsd$ to ? $\text{DefaultNumberOption}(mnsd, 1, 21, 1)$.
    c. Set $mxsd$ to ? $\text{DefaultNumberOption}(mxsd, mnsd, 21, 21)$.
    d. Set $\text{intlObj}.[[\text{MinimumSignificantDigits}]]$ to $mnsd$.
    e. Set $\text{intlObj}.[[\text{MaximumSignificantDigits}]]$ to $mxsd$.
15. If $needFd$ is $\text{true}$, then
    a. If $hasFd$ is $\text{true}$, then
       i. Set $mnfd$ to ? $\text{DefaultNumberOption}(mnfd, 0, 20, \text{undefined})$.
       ii. Set $mxfd$ to ? $\text{DefaultNumberOption}(mxfd, 0, 20, \text{undefined})$.
       iii. If $mnfd$ is $\text{undefined}$, set $mnfd$ to $\text{min}(mnfd\text{Default}, mxfd)$.
       iv. Else if $mxfd$ is $\text{undefined}$, set $mxfd$ to $\text{max}(mxfd\text{Default}, mnfd)$.
       v. Else if $mnfd$ is greater than $mxfd$, throw a $\text{RangeError}$ exception.
       vi. Set $\text{intlObj}.[[\text{MinimumFractionDigits}]]$ to $mnfd$.
       vii. Set $\text{intlObj}.[[\text{MaximumFractionDigits}]]$ to $mxfd$.
    b. Else,
       i. Set $\text{intlObj}.[[\text{MinimumFractionDigits}]]$ to $mnfd\text{Default}$.
       ii. Set $\text{intlObj}.[[\text{MaximumFractionDigits}]]$ to $mxfd\text{Default}$.
16. If $needSd$ is $\text{false}$ and $needFd$ is $\text{false}$, then
    a. Set $\text{intlObj}.[[\text{RoundingType}]]$ to $\text{compactRounding}$.
17. Else if $hasSd$ is $\text{true}$, then
    a. Set $\text{intlObj}.[[\text{RoundingType}]]$ to $\text{significantDigits}$.
18. Else,
    a. Set $\text{intlObj}.[[\text{RoundingType}]]$ to $\text{fractionDigits}$.

15.1.4 SetNumberFormatUnitOptions ($\text{intlObj, options}$)

The abstract operation SetNumberFormatUnitOptions resolves the user-specified options relating to units onto the intl object.
1. Assert: Type(intlObj) is Object.
2. Assert: Type(options) is Object.
4. Set intlObj.[[Style]] to style.
6. If currency is undefined, then
   a. If style is "currency", throw a TypeError exception.
7. Else,
   a. If ! IsWellFormedCurrencyCode(currency) is false, throw a RangeError exception.
11. If unit is undefined, then
    a. If style is "unit", throw a TypeError exception.
12. Else,
    a. If ! IsWellFormedUnitIdentifier(unit) is false, throw a RangeError exception.
14. If style is "currency", then
    a. Set intlObj.[[Currency]] to the ASCII-uppercase of currency.
    b. Set intlObj.[[CurrencyDisplay]] to currencyDisplay.
    c. Set intlObj.[[CurrencySign]] to currencySign.
15. If style is "unit", then
    a. Set intlObj.[[Unit]] to unit.
    b. Set intlObj.[[UnitDisplay]] to unitDisplay.

15.2 Properties of the Intl.NumberFormat Constructor

The Intl.NumberFormat constructor has the following properties:

15.2.1 Intl.NumberFormat.prototype

The value of Intl.NumberFormat.prototype is %NumberFormat.prototype%. This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

15.2.2 Intl.NumberFormat.supportedLocalesOf ( locales [, options ] )

When the supportedLocalesOf method is called with arguments locales and options, the following steps are taken:

1. Let availableLocales be %NumberFormat%.[[AvailableLocales]].
2. Let requestedLocales be ? CanonicalizeLocaleList(locales).

15.2.3 Internal slots

© Ecma International
The value of the [[AvailableLocales]] internal slot is implementation-defined within the constraints described in 9.1.

The value of the [[RelevantExtensionKeys]] internal slot is « "nu" ».

NOTE 1  Unicode Technical Standard 35 describes three locale extension keys that are relevant to number formatting: "cu" for currency, "cf" for currency format style, and "nu" for numbering system. Intl.NumberFormat, however, requires that the currency of a currency format is specified through the currency property in the options objects, and the currency format style of a currency format is specified through the currencySign property in the options objects.

The value of the [[LocaleData]] internal slot is implementation-defined within the constraints described in 9.1 and the following additional constraints:

- The list that is the value of the "nu" field of any locale field of [[LocaleData]] must not include the values "native", "tradition", or "finance".
- [[LocaleData]].[[locale]] must have a [[patterns]] field for all locale values locale. The value of this field must be a Record, which must have fields with the names of the four number format styles: "decimal", "percent", "currency", and "unit".
- The two fields "currency" and "unit" noted above must be Records with at least one field, "fallback". The "currency" may have additional fields with keys corresponding to currency codes according to 6.3. Each field of "currency" must be a Record with fields corresponding to the possible currencyDisplay values: "code", "symbol", "narrowSymbol", and "name". Each of those fields must contain a Record with fields corresponding to the possible currencySign values: "standard" or "accounting". The "unit" field (of [[LocaleData]].[[locale]]) may have additional fields beyond the required field "fallback" with keys corresponding to core measurement unit identifiers corresponding to 6.5. Each field of "unit" must be a Record with fields corresponding to the possible unitDisplay values: "narrow", "short", and "long".
- All of the leaf fields so far described for the patterns tree ("decimal", "percent", great-grandchildren of "currency", and grandchildren of "unit") must be Records with the keys "positivePattern", "zeroPattern", and "negativePattern".
- The value of the aforementioned fields (the sign-dependent pattern fields) must be string values that must contain the substring "[number]", "positivePattern" must contain the substring "[plusSign]" but not "minusSign"; "negativePattern" must contain the substring "[plusSign]" but not "plusSign"; and "zeroPattern" must not contain either "plusSign" or "minusSign". Additionally, the values within the "percent" field must also contain the substring "[percentSign]"; the values within the "currency" field must also contain one or more of the following substrings: "[currencyCode]", "[currencyPrefix]", or "[currencySuffix]"; and the values within the "unit" field must also contain one or more of the following substrings: "[unitPrefix]" or "[unitSuffix]". The pattern strings must not contain any characters in the General Category "Number, decimal digit" as specified by the Unicode Standard.
- [[LocaleData]].[[locale]] must also have a [[notationSubPatterns]] field for all locale values locale. The value of this field must be a Record, which must have two fields: [[scientific]] and [[compact]]. The [[scientific]] field must be a string value containing the substrings "[number]", "[scientificSeparator]", and "[scientificExponent]". The [[compact]] field must be a Record with two fields: "short" and "long". Each of these fields must be a Record with integer keys corresponding to all discrete magnitudes the implementation supports for compact notation. Each of these fields must be a string value which may contain the substring "[number]". Strings descended from "short" must contain the substring "compactSymbol", and strings descended from "long" must contain the substring "compactName".

NOTE 2  It is recommended that implementations use the locale data provided by the Common Locale.
15.3 Properties of the Intl.NumberFormat Prototype Object

The Intl.NumberFormat prototype object is itself an ordinary object. `NumberFormat.prototype` is not an Intl.NumberFormat instance and does not have an `[[InitializedNumberFormat]]` internal slot or any of the other internal slots of Intl.NumberFormat instance objects.

15.3.1 Intl.NumberFormat.prototype.constructor

The initial value of `Intl.NumberFormat.prototype.constructor` is `%NumberFormat%`.

15.3.2 Intl.NumberFormat.prototype[@@toStringTag]

The initial value of the `@@toStringTag` property is the String value "Intl.NumberFormat".

This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

15.3.3 get Intl.NumberFormat.prototype.format

Intl.NumberFormat.prototype.format is an accessor property whose set accessor function is undefined. Its get accessor function performs the following steps:

1. Let `nf` be the this value.
2. If the implementation supports the normative optional constructor mode of 4.3 Note 1, then
   a. Set `nf` to ? UnwrapNumberFormat(`nf`).
4. If `nf. [[BoundFormat]]` is undefined, then
   a. Let `F` be a new built-in function object as defined in Number Format Functions (15.5.2).
   b. Set `F. [[NumberFormat]]` to `nf`.
   c. Set `nf. [[BoundFormat]]` to `F`.
5. Return `nf. [[BoundFormat]]`.

NOTE The returned function is bound to `nf` so that it can be passed directly to `Array.prototype.map` or other functions. This is considered a historical artefact, as part of a convention which is no longer followed for new features, but is preserved to maintain compatibility with existing programs.

15.3.4 Intl.NumberFormat.prototype.formatToParts( value )

When the `formatToParts` method is called with an optional argument `value`, the following steps are taken:

1. Let `nf` be the this value.
2. Perform ? RequireInternalSlot(`nf`, `[[InitializedNumberFormat]]`).
3. Let `x` be ? ToNumeric(`value`).
4. Return ? FormatNumericToParts(`nf`, `x`).
15.3.5 Intl.NumberFormat.prototype.resolvedOptions ( )

This function provides access to the locale and options computed during initialization of the object.

1. Let \( nf \) be the this value.
2. If the implementation supports the normative optional constructor mode of 4.3 Note 1, then
   a. Set \( nf \) to ? UnwrapNumberFormat(\( nf \)).
3. Perform ? RequireInternalSlot(\( nf \), [[InitializedNumberFormat]]).
4. Let \( options \) be ! OrdinaryObjectCreate(%Object.prototype%).
5. For each row of Table 11, except the header row, in table order, do
   a. Let \( p \) be the Property value of the current row.
   b. Let \( v \) be the value of \( nf \)'s internal slot whose name is the Internal Slot value of the current row.
   c. If \( v \) is not undefined, then
      i. Perform ! CreateDataPropertyOrThrow(\( options \), \( p \), \( v \)).
6. Return \( options \).

15.4 Properties of Intl.NumberFormat Instances
Intl.NumberFormat instances are ordinary objects that inherit properties from %NumberFormat.prototype%.

Intl.NumberFormat instances have an [[InitializedNumberFormat]] internal slot.

Intl.NumberFormat instances also have several internal slots that are computed by the constructor:

- [[Locale]] is a String value with the language tag of the locale whose localization is used for formatting.
- [[DataLocale]] is a String value with the language tag of the nearest locale for which the implementation has data to perform the formatting operation. It will be a parent locale of [[Locale]].
- [[NumberingSystem]] is a String value with the “type” given in Unicode Technical Standard 35 for the numbering system used for formatting.
- [[Style]] is one of the String values "decimal", "currency", "percent", or "unit", identifying the type of quantity being measured.
- [[Currency]] is a String value with the currency code identifying the currency to be used if formatting with the "currency" unit type. It is only used when [[Style]] has the value "currency".
- [[CurrencyDisplay]] is one of the String values "code", "symbol", "narrowSymbol", or "name", specifying whether to display the currency as an ISO 4217 alphabetic currency code, a localized currency symbol, or a localized currency name if formatting with the "currency" style. It is only used when [[Style]] has the value "currency".
- [[CurrencySign]] is one of the String values "standard" or "accounting", specifying whether to render negative numbers in accounting format, often signified by parenthesis. It is only used when [[Style]] has the value "currency" and when [[SignDisplay]] is not "never".
- [[Unit]] is a core unit identifier, as defined by Unicode Technical Standard #35, Part 2, Section 6. It is only used when [[Style]] has the value "unit".
- [[UnitDisplay]] is one of the String values "short", "narrow", or "long", specifying whether to display the unit as a symbol, narrow symbol, or localized long name if formatting with the "unit" style. It is only used when [[Style]] has the value "unit".
- [[MinimumIntegerDigits]] is a non-negative integer Number value indicating the minimum integer digits to be used. Numbers will be padded with leading zeroes if necessary.
- [[MinimumFractionDigits]] and [[MaximumFractionDigits]] are non-negative integer Number values indicating the minimum and maximum fraction digits to be used. Numbers will be rounded or padded with trailing zeroes if necessary. These properties are only used when [[RoundingType]] is fractionDigits.
- [[MinimumSignificantDigits]] and [[MaximumSignificantDigits]] are positive integer Number values indicating the minimum and maximum fraction digits to be shown. If present, the formatter uses however many fraction digits are required to display the specified number of significant digits. These properties are only used when [[RoundingType]] is significantDigits.
- [[UseGrouping]] is a Boolean value indicating whether a grouping separator should be used.
- [[RoundingType]] is one of the values fractionDigits, significantDigits, or compactRounding, indicating which rounding strategy to use. If fractionDigits, the number is rounded according to [[MinimumFractionDigits]] and [[MaximumFractionDigits]], as described above. If significantDigits, the number is rounded according to [[MinimumSignificantDigits]] and [[MaximumSignificantDigits]] as described above. If compactRounding, the number is rounded to 1 maximum fraction digit if there is 1 digit before the decimal separator, and otherwise round to 0 fraction digits.
- [[Notation]] is one of the String values "standard", "scientific", "engineering", or "compact", specifying whether the number should be displayed without scaling, scaled to the units place with the power of ten in scientific notation, scaled to the nearest thousand with the power of ten in scientific notation, or scaled to the nearest locale-dependent compact decimal notation power of ten with the corresponding compact decimal notation affix.
• [[CompactDisplay]] is one of the String values "short" or "long", specifying whether to display compact notation affixes in short form ("5K") or long form ("5 thousand") if formatting with the "compact" notation. It is only used when [[Notation]] has the value "compact".

• [[SignDisplay]] is one of the String values "auto", "always", "never", or "exceptZero", specifying whether to show the sign on negative numbers only, positive and negative numbers including zero, neither positive nor negative numbers, or positive and negative numbers but not zero. In scientific notation, this slot affects the sign display of the mantissa but not the exponent.

Finally, Intl.NumberFormat instances have a [[BoundFormat]] internal slot that caches the function returned by the format accessor (15.3.3).

### 15.5 Abstract Operations for NumberFormat Objects

#### 15.5.1 CurrencyDigits (currency)

When the CurrencyDigits abstract operation is called with an argument currency (which must be an uppercase String value), the following steps are taken:

1. If the ISO 4217 currency and funds code list contains currency as an alphabetic code, return the minor unit value corresponding to the currency from the list; otherwise, return 2.

#### 15.5.2 Number Format Functions

A Number format function is an anonymous built-in function that has a [[NumberFormat]] internal slot.

When a Number format function \( F \) is called with optional argument value, the following steps are taken:

1. Let \( nf \) be \( F.[[NumberFormat]] \).
2. Assert: Type(\( nf \)) is Object and \( nf \) has an [[InitializedNumberFormat]] internal slot.
3. If value is not provided, let value be undefined.
4. Let \( x \) be ? ToNumeric(value).
5. Return ? FormatNumeric(\( nf \), \( x \)).

The "length" property of a Number format function is 1.

#### 15.5.3 FormatNumericToString (intlObject, x)

The FormatNumericToString abstract operation is called with arguments intlObject (which must be an object with [[RoundingType]], [[MinimumSignificantDigits]], [[MaximumSignificantDigits]], [[MinimumIntegerDigits]], [[MinimumFractionDigits]], and [[MaximumFractionDigits]] internal slots), and \( x \) (which must be a Number or BigInt value), and returns a Record containing two values: \( x \) as a String value with digits formatted according to the five formatting parameters in the field [[FormattedString]], and the final floating decimal value of \( x \) after rounding has been performed in the field [[RoundedNumber]].

1. If \( \mathbb{R}(x) < 0 \) or \( x \) is -0, let isNegative be true; else let isNegative be false.
2. If isNegative, then
   a. Let \( x \) be -\( x \).
3. If intlObject.[[RoundingType]] is significantDigits, then
The abstract operation PartitionNumberPattern takes arguments numberFormat (an object initialized as a NumberFormat) and x (a Number or a BigInt). It creates the parts representing the mathematical value of x according to the effective locale and the formatting options of numberFormat. It performs the following steps when called:

1. Let exponent be 0.
2. If x is NaN, then
   a. Let n be an implementation- and locale-dependent (ILD) String value indicating the NaN value.
3. Else if x is +∞, then
   a. Let n be an ILD String value indicating positive infinity.
4. Else if x is -∞, then
   a. Let n be an ILD String value indicating negative infinity.
5. Else,
   a. Set x to \( \mathbb{R}(x) \).
   b. If numberFormat.[[Style]] is "percent", set x to 100 \( \times \) x.
   c. Let exponent be ComputeExponent(numberFormat, x).
   d. Set x to \( x \times 10^{-\text{exponent}} \).
   e. Let formatNumberResult be FormatNumericToString(numberFormat, x).
   f. Let n be formatNumberResult.[[FormattedString]].
   g. Set x to formatNumberResult.[[RoundedNumber]].
6. Let pattern be GetNumberFormatPattern(numberFormat, x).
7. Let result be a new empty List.
8. Let patternParts be PartitionPattern(pattern).
9. For each Record { [[Type]], [[Value]] } patternPart of patternParts, do
   a. Let p be patternPart.[[Type]].
b. If \( p \) is "literal", then
   i. Append a new Record \{ [[Type]]: "literal", [[Value]]: \( \text{patternPart}.[[\text{Value}]] \) \} as the last element of result.

c. Else if \( p \) is equal to "number", then
   i. Let notationSubParts be PartitionNotationSubPattern\( (numberFormat, x, n, \text{exponent}) \).
   ii. Append all elements of notationSubParts to result.

d. Else if \( p \) is equal to "plusSign", then
   i. Let plusSignSymbol be the ILND String representing the plus sign.
   ii. Append a new Record \{ [[Type]]: "plusSign", [[Value]]: plusSignSymbol \} as the last element of result.

e. Else if \( p \) is equal to "minusSign", then
   i. Let minusSignSymbol be the ILND String representing the minus sign.
   ii. Append a new Record \{ [[Type]]: "minusSign", [[Value]]: minusSignSymbol \} as the last element of result.

f. Else if \( p \) is equal to "percentSign" and \( numberFormat.[[\text{Style}]] \) is "percent", then
   i. Let percentSignSymbol be the ILND String representing the percent sign.
   ii. Append a new Record \{ [[Type]]: "percentSign", [[Value]]: percentSignSymbol \} as the last element of result.

g. Else if \( p \) is equal to "unitPrefix" and \( numberFormat.[[\text{Style}]] \) is "unit", then
   i. Let \( \text{unit} \) be \( numberFormat.[[\text{Unit}]] \).
   ii. Let \( \text{unitDisplay} \) be \( numberFormat.[[\text{UnitDisplay}]] \).
   iii. Let \( \mu \) be an ILD String value representing \( \text{unit} \) before \( x \) in \( \text{unitDisplay} \) form, which may depend on \( x \) in languages having different plural forms.
   iv. Append a new Record \{ [[Type]]: "unit", [[Value]]: \( \mu \) \} as the last element of result.

h. Else if \( p \) is equal to "unitSuffix" and \( numberFormat.[[\text{Style}]] \) is "unit", then
   i. Let \( \text{unit} \) be \( numberFormat.[[\text{Unit}]] \).
   ii. Let \( \text{unitDisplay} \) be \( numberFormat.[[\text{UnitDisplay}]] \).
   iii. Let \( \mu \) be an ILD String value representing \( \text{unit} \) after \( x \) in \( \text{unitDisplay} \) form, which may depend on \( x \) in languages having different plural forms.
   iv. Append a new Record \{ [[Type]]: "unit", [[Value]]: \( \mu \) \} as the last element of result.

i. Else if \( p \) is equal to "currencyCode" and \( numberFormat.[[\text{Style}]] \) is "currency", then
   i. Let \( \text{currency} \) be \( numberFormat.[[\text{Currency}]] \).
   ii. Let \( \text{cd} \) be \( \text{currency} \).
   iii. Append a new Record \{ [[Type]]: "currency", [[Value]]: \( \text{cd} \) \} as the last element of result.

j. Else if \( p \) is equal to "currencyPrefix" and \( numberFormat.[[\text{Style}]] \) is "currency", then
   i. Let \( \text{currency} \) be \( numberFormat.[[\text{Currency}]] \).
   ii. Let \( \text{currencyDisplay} \) be \( numberFormat.[[\text{CurrencyDisplay}]] \).
   iii. Let \( \text{cd} \) be an ILD String value representing \( \text{currency} \) before \( x \) in \( \text{currencyDisplay} \) form, which may depend on \( x \) in languages having different plural forms.
   iv. Append a new Record \{ [[Type]]: "currency", [[Value]]: \( \text{cd} \) \} as the last element of result.

k. Else if \( p \) is equal to "currencySuffix" and \( numberFormat.[[\text{Style}]] \) is "currency", then
   i. Let \( \text{currency} \) be \( numberFormat.[[\text{Currency}]] \).
   ii. Let \( \text{currencyDisplay} \) be \( numberFormat.[[\text{CurrencyDisplay}]] \).
   iii. Let \( \text{cd} \) be an ILD String value representing \( \text{currency} \) after \( x \) in \( \text{currencyDisplay} \) form, which may depend on \( x \) in languages having different plural forms. If the implementation does not have such a representation of \( \text{currency} \), use \( \text{currency} \) itself.
   iv. Append a new Record \{ [[Type]]: "currency", [[Value]]: \( \text{cd} \) \} as the last element of result.

l. Else,
i. Let unknown be an ILND String based on \( x \) and \( p \).

ii. Append a new Record \{ [[Type]]: "unknown", [[Value]]: unknown \} as the last element of result.

10. Return result.

### 15.5.5 PartitionNotationSubPattern (numberFormat, \( x \), \( n \), exponent)

The PartitionNotationSubPattern abstract operation is called with arguments numberFormat (which must be an object initialized as a NumberFormat), \( x \) (which is a numeric value after rounding is applied), \( n \) (which is an intermediate formatted string), and exponent (an integer), and creates the corresponding parts for the number and notation according to the effective locale and the formatting options of numberFormat. The following steps are taken:

1. Let result be a new empty List.
2. If \( x \) is NaN, then
   a. Append a new Record \{ [[Type]]: "nan", [[Value]]: \( n \) \} as the last element of result.
3. Else if \( x \) is a non-finite Number, then
   a. Append a new Record \{ [[Type]]: "infinity", [[Value]]: \( n \) \} as the last element of result.
4. Else,
   a. Let notationSubPattern be GetNotationSubPattern(numberFormat, exponent).
   b. Let patternParts be PartitionPattern(notationSubPattern).
   c. For each Record \{ [[Type]], [[Value]] \} patternPart of patternParts, do
      i. Let \( p \) be patternPart.[[Type]].
      ii. If \( p \) is "literal", then
          1. Append a new Record \{ [[Type]]: "literal", [[Value]]: patternPart.[[Value]] \} as the last element of result.
      iii. Else if \( p \) is equal to "number", then
          1. If the numberFormat.[[NumberingSystem]] matches one of the values in the "Numbering System" column of Table 12 below, then
              a. Let digits be a List whose 10 String valued elements are the UTF-16 string representations of the 10 digits specified in the "Digits" column of the matching row in Table 12.
              b. Replace each digit in \( n \) with the value of digits[digit].
          2. Else use an implementation dependent algorithm to map \( n \) to the appropriate representation of \( n \) in the given numbering system.
        3. Let decimalSepIndex be ! StringIndexOf(n, ".", 0).
    4. If decimalSepIndex > 0, then
       a. Let integer be the substring of \( n \) from position 0, inclusive, to position decimalSepIndex, exclusive.
       b. Let fraction be the substring of \( n \) from position decimalSepIndex, exclusive, to the end of \( n \).
    5. Else,
       a. Let integer be \( n \).
       b. Let fraction be undefined.
   6. If the numberFormat.[[UseGrouping]] is true, then
      a. Let groupSepSymbol be the implementation-, locale-, and numbering system-dependent (ILND) String representing the grouping separator.
      b. Let groups be a List whose elements are, in left to right order, the substrings defined by ILND set of locations within the integer.
c. **Assert**: The number of elements in `groups` List is greater than 0.
d. **Repeat**, while `groups` List is not empty,
   i. Remove the first element from `groups` and let `integerGroup` be the value of that element.
   ii. Append a new Record { [[Type]]: "integer", [[Value]]: `integerGroup` } as the last element of `result`.
   iii. If `groups` List is not empty, then
      i. Append a new Record { [[Type]]: "group", [[Value]]: `groupSepSymbol` } as the last element of `result`.
7. **Else,**
   a. Append a new Record { [[Type]]: "integer", [[Value]]: `integer` } as the last element of `result`.
8. If `fraction` is **not** undefined, then
   a. Let `decimalSepSymbol` be the ILND String representing the decimal separator.
   b. Append a new Record { [[Type]]: "decimal", [[Value]]: `decimalSepSymbol` } as the last element of `result`.
   c. Append a new Record { [[Type]]: "fraction", [[Value]]: `fraction` } as the last element of `result`.
iv. Else if `p` is equal to "compactSymbol", then
   1. Let `compactSymbol` be an ILD string representing `exponent` in short form, which may depend on `x` in languages having different plural forms. The implementation must be able to provide this string, or else the pattern would not have a "`compactSymbol`" placeholder.
   2. Append a new Record { [[Type]]: "compact", [[Value]]: `compactSymbol` } as the last element of `result`.
   v. Else if `p` is equal to "compactName", then
   1. Let `compactName` be an ILD string representing `exponent` in long form, which may depend on `x` in languages having different plural forms. The implementation must be able to provide this string, or else the pattern would not have a "`compactName`" placeholder.
   2. Append a new Record { [[Type]]: "compact", [[Value]]: `compactName` } as the last element of `result`.
   vi. Else if `p` is equal to "scientificSeparator", then
   1. Let `scientificSeparator` be the ILND String representing the exponent separator.
   2. Append a new Record { [[Type]]: "exponentSeparator", [[Value]]: `scientificSeparator` } as the last element of `result`.
   vii. Else if `p` is equal to "scientificExponent", then
   1. If `exponent` < 0, then
      a. Let `minusSignSymbol` be the ILND String representing the minus sign.
      b. Append a new Record { [[Type]]: "exponentMinusSign", [[Value]]: `minusSignSymbol` } as the last element of `result`.
      c. Let `exponent` be -`exponent`.
   2. Let `exponentResult` be ToRawFixed(`exponent`, 1, 0, 0).
   3. Append a new Record { [[Type]]: "exponentInteger", [[Value]]: `exponentResult` } as the last element of `result`.
   viii. Else,
   1. Let `unknown` be an ILND String based on `x` and `p`.
   2. Append a new Record { [[Type]]: "unknown", [[Value]]: `unknown` } as the last element of `result`.
5. Return `result`.

</table>

**NOTE 1** The computations rely on String values and locations within numeric strings that are dependent upon the implementation and the effective locale of `numberFormat` ("ILD") or upon the implementation, the effective locale, and the numbering system of `numberFormat` ("ILND"). The ILD and ILND Strings mentioned, other than those for currency names, must not contain any characters in the General Category "Number, decimal digit" as specified by the Unicode Standard.

**NOTE 2** It is recommended that implementations use the locale provided by the Common Locale Data Repository (available at https://cldr.unicode.org/).

### 15.5.6 FormatNumeric ( `numberFormat`, `x` )

The FormatNumeric abstract operation is called with arguments `numberFormat` (which must be an object initialized as a NumberFormat) and `x` (which must be a Number or BigInt value), and performs the following steps:

1. Let `parts` be `PartitionNumberPattern(numberFormat, x)`.
2. Let `result` be the empty String.
3. For each `Record { [[Type]], [[Value]] } part` in `parts`, do
   a. Set `result` to the string-concatenation of `result` and `part.[[Value]]`.
4. Return `result`.

### 15.5.7 FormatNumericToParts ( `numberFormat`, `x` )

The FormatNumericToParts abstract operation is called with arguments `numberFormat` (which must be an object initialized as a NumberFormat) and `x` (which must be a Number or BigInt value), and performs the following...
1. Let \( \text{parts} \) be \( \text{PartitionNumberPattern}(\text{numberFormat}, x) \).
2. Let \( \text{result} \) be \( \text{ArrayCreate}(0) \).
3. Let \( n \) be 0.
4. For each Record \([[[\text{Type}]],[[\text{Value}]}} \) \( \text{part} \) in \( \text{parts} \), do
   a. Let \( O \) be \( \text{ OrdinaryObjectCreate}(%\text{Object.prototype}%) \).
   b. Perform \( \text{CreateDataPropertyOrThrow} (O, "\text{type}", \text{part}[[\text{Type}]]). \)
   c. Perform \( \text{CreateDataPropertyOrThrow} (O, "\text{value}", \text{part}[[\text{Value}]]). \)
   d. Perform \( \text{CreateDataPropertyOrThrow} (\text{result}, !\text{ToString}(n), O) \).
   e. Increment \( n \) by 1.
5. Return \( \text{result} \).

When the \( \text{ToRawPrecision} \) abstract operation is called with arguments \( x \) (which must be a finite non-negative Number or BigInt), \( \text{minPrecision} \), and \( \text{maxPrecision} \) (both must be integers between 1 and 21), the following steps are taken:

1. Set \( x \) to \( \mathbb{R}(x) \).
2. Let \( p \) be \( \text{maxPrecision} \).
3. If \( x = 0 \), then
   a. Let \( m \) be the String consisting of \( p \) occurrences of the character "0".
   b. Let \( e \) be 0.
   c. Let \( x\text{Final} \) be 0.
4. Else,
   a. Let \( e \) and \( n \) be integers such that \( 10^p - 1 \leq n < 10^p \) and for which \( n \times 10^e \cdot p + 1 - x \) is as close to zero as possible. If there are two such sets of \( e \) and \( n \), pick the \( e \) and \( n \) for which \( n \times 10^e \cdot p + 1 \) is larger.
   b. Let \( m \) be the String consisting of the digits of the decimal representation of \( n \) (in order, with no leading zeroes).
   c. Let \( x\text{Final} \) be \( n \times 10^e \cdot p + 1 \).
5. If \( e \geq p - 1 \), then
   a. Let \( m \) be the string-concatenation of \( m \) and \( e - p + 1 \) occurrences of the character "0".
   b. Let \( \text{int} \) be \( e + 1 \).
6. Else if \( e \geq 0 \), then
   a. Let \( m \) be the string-concatenation of the first \( e+1 \) characters of \( m \), the character ".", and the remaining \( p-(e+1) \) characters of \( m \).
   b. Let \( \text{int} \) be \( e + 1 \).
7. Else,
   a. Assert: \( e < 0 \).
   b. Let \( m \) be the string-concatenation of "0.", \(-(e+1)\) occurrences of the character "0", and \( m \).
   c. Let \( \text{int} \) be 1.
8. If \( m \) contains the character ",", and \( \text{maxPrecision} > \text{minPrecision} \), then
   a. Let \( \text{cut} \) be \( \text{maxPrecision} - \text{minPrecision} \).
   b. Repeat, while \( \text{cut} > 0 \) and the last character of \( m \) is "0",
      i. Remove the last character from \( m \).
      ii. Decrease \( \text{cut} \) by 1.
   c. If the last character of \( m \) is ",", then
i. Remove the last character from \( m \).

9. Return the Record \{ [[FormattedString]]: \( m \), [[RoundedNumber]]: \( x_{\text{Final}} \), [[IntegerDigitsCount]]: \( \text{int} \) \}.

15.5.9 ToRawFixed ( \( x, \text{minInteger}, \text{minFraction}, \text{maxFraction} \) )

When the ToRawFixed abstract operation is called with arguments \( x \) (which must be a finite non-negative Number or BigInt), \( \text{minInteger} \) (which must be an integer between 1 and 21), \( \text{minFraction} \), and \( \text{maxFraction} \) (which must be integers between 0 and 20), the following steps are taken:

1. Set \( x \) to \( \mathbb{R}(x) \).
2. Let \( f \) be \( \text{maxFraction} \).
3. Let \( n \) be an integer for which the exact mathematical value of \( n / 10^f - x \) is as close to zero as possible. If there are two such \( n \), pick the larger \( n \).
4. Let \( x_{\text{Final}} \) be \( n / 10^f \).
5. If \( n = 0 \), let \( m \) be "0". Otherwise, let \( m \) be the String consisting of the digits of the decimal representation of \( n \) (in order, with no leading zeroes).
6. If \( f \neq 0 \), then
   a. Let \( k \) be the number of characters in \( m \).
   b. If \( k \leq f \), then
      i. Let \( z \) be the String value consisting of \( f+1-k \) occurrences of the character "0".
      ii. Let \( m \) be the string-concatenation of \( z \) and \( m \).
      iii. Let \( k \) be \( f+1 \).
   c. Let \( a \) be the first \( k-f \) characters of \( m \), and let \( b \) be the remaining \( f \) characters of \( m \).
   d. Let \( m \) be the string-concatenation of \( a \), ".", and \( b \).
   e. Let \( \text{int} \) be the number of characters in \( a \).
7. Else, let \( \text{int} \) be the number of characters in \( m \).
8. Let \( \text{cut} \) be \( \text{maxFraction} - \text{minFraction} \).
9. Repeat, while \( \text{cut} > 0 \) and the last character of \( m \) is "0",
   a. Remove the last character from \( m \).
   b. Decrease \( \text{cut} \) by 1.
10. If the last character of \( m \) is ".", then
    a. Remove the last character from \( m \).
11. Return the Record \{ [[FormattedString]]: \( m \), [[RoundedNumber]]: \( x_{\text{Final}} \), [[IntegerDigitsCount]]: \( \text{int} \) \}.

NORMATIVE OPTIONAL

15.5.10 UnwrapNumberFormat ( \( nf \) )

The UnwrapNumberFormat abstract operation returns the NumberFormat instance of its input object, which is either the value itself or a value associated with it by \%NumberFormat\% according to the normative optional constructor mode of 4.3 Note 1.

1. If Type(\( nf \)) is not Object, throw a TypeError exception.
2. If \( nf \) does not have an [[InitializedNumberFormat]] internal slot and
   \[ \text{OrdinaryHasInstance}(%\text{NumberFormat}%, \( nf \)) \] is true, then
   a. Return \( \text{Get}(nf, %\text{Intl}.[[\text{FallbackSymbol}]]) \).
3. Return \( nf \).
The abstract operation GetNumberFormatPattern considers the resolved unit-related options in the number format object along with the final scaled and rounded number being formatted and returns a pattern, a String value as described in 15.2.3.

1. Let `localeData` be `%NumberFormat%.[[LocaleData]].
2. Let `dataLocale` be `numberFormat`.[[DataLocale]].
3. Let `dataLocaleData` be `localeData`.[[<dataLocale>]].
4. Let `patterns` be `dataLocaleData`.[[patterns]].
5. Assert: `patterns` is a Record (see 15.2.3).
6. Let `style` be `numberFormat`.[[Style]].
7. If `style` is "percent", then
   a. Let `patterns` be `patterns`.[[percent]].
8. Else if `style` is "unit", then
   a. Let `unit` be `numberFormat`.[[Unit]].
   b. Let `unitDisplay` be `numberFormat`.[[UnitDisplay]].
   c. Let `patterns` be `patterns`.[[unit]].
   d. If `patterns` doesn't have a field [[<unit>]], then
      i. Let `unit` be "fallback".
   e. Let `patterns` be `patterns`.[[<unit>]].
   f. Let `patterns` be `patterns`.[[<unitDisplay>]].
9. Else if `style` is "currency", then
   a. Let `currency` be `numberFormat`.[[Currency]].
   b. Let `currencyDisplay` be `numberFormat`.[[CurrencyDisplay]].
   c. Let `currencySign` be `numberFormat`.[[CurrencySign]].
   d. Let `patterns` be `patterns`.[[currency]].
   e. If `patterns` doesn't have a field [[<currency>]], then
      i. Let `currency` be "fallback".
   f. Let `patterns` be `patterns`.[[<currency>]].
   g. Let `patterns` be `patterns`.[[<currencyDisplay>]].
   h. Let `patterns` be `patterns`.[[<currencySign>]].
10. Else,
    a. Assert: `style` is "decimal".
    b. Let `patterns` be `patterns`.[[decimal]].
11. Let `signDisplay` be `numberFormat`.[[SignDisplay]].
12. If `signDisplay` is "never", then
    a. Let `pattern` be `patterns`.[[zeroPattern]].
13. Else if `signDisplay` is "auto", then
    a. If `x` is 0 or `x > 0` or `x` is NaN, then
       i. Let `pattern` be `patterns`.[[zeroPattern]].
    b. Else,
       i. Let `pattern` be `patterns`.[[negativePattern]].
14. Else if `signDisplay` is "always", then
    a. If `x` is 0 or `x > 0` or `x` is NaN, then
       i. Let `pattern` be `patterns`.[[positivePattern]].
    b. Else,
       i. Let `pattern` be `patterns`.[[negativePattern]].
15. Else,
a. Assert: \( \text{signDisplay} \) is "exceptZero".
b. If \( x \) is \( \text{NaN} \), or if \( x \) is finite and \( x \equiv 0 \), then
   i. Let \( \text{pattern} \) be \( \text{patterns}.[[\text{zeroPattern}]] \).
c. Else if \( x > 0 \), then
   i. Let \( \text{pattern} \) be \( \text{patterns}.[[\text{positivePattern}]] \).
d. Else,
   i. Let \( \text{pattern} \) be \( \text{patterns}.[[\text{negativePattern}]] \).
16. Return \( \text{pattern} \).

15.5.12 GetNotationSubPattern ( \( \text{numberFormat} \), \( \text{exponent} \) )

The abstract operation GetNotationSubPattern considers the resolved notation and \( \text{exponent} \), and returns a String value for the notation sub pattern as described in 15.2.3.

1. Let \( \text{localeData} \) be \( \%\text{NumberFormat}\%.[[\text{LocaleData}]] \).
2. Let \( \text{dataLocale} \) be \( \text{numberFormat}.[[\text{DataLocale}]] \).
3. Let \( \text{dataLocaleData} \) be \( \text{localeData}[[<\text{dataLocale}>]] \).
4. Let \( \text{notationSubPatterns} \) be \( \text{dataLocaleData}.[[\text{notationSubPatterns}]] \).
5. Assert: \( \text{notationSubPatterns} \) is a Record (see 15.2.3).
6. Let \( \text{notation} \) be \( \text{numberFormat}.[[\text{Notation}]] \).
7. If \( \text{notation} \) is "scientific" or \( \text{notation} \) is "engineering", then
   a. Return \( \text{notationSubPatterns}.[[\text{scientific}]] \).
8. Else if \( \text{exponent} \) is not 0, then
   a. Assert: \( \text{notation} \) is "compact".
   b. Let \( \text{compactDisplay} \) be \( \text{numberFormat}.[[\text{CompactDisplay}]] \).
   c. Let \( \text{compactPatterns} \) be \( \text{notationSubPatterns}.[[\text{compact}]].[[<\text{compactDisplay}>]] \).
   d. Return \( \text{compactPatterns}.[[<\text{exponent}>]] \).
9. Else,
   a. Return "[number]".

15.5.13 ComputeExponent ( \( \text{numberFormat} \), \( x \) )

The abstract operation ComputeExponent computes an exponent (power of ten) by which to scale \( x \) according to the number formatting settings. It handles cases such as 999 rounding up to 1000, requiring a different exponent.

1. If \( x = 0 \), then
   a. Return 0.
2. If \( x < 0 \), then
   a. Let \( x = -x \).
3. Let \( \text{magnitude} \) be the base 10 logarithm of \( x \) rounded down to the nearest integer.
4. Let \( \text{exponent} \) be \( \text{ComputeExponentForMagnitude}(\text{numberFormat}, \text{magnitude}) \).
5. Let \( x \) be \( x \times 10^{\text{exponent}} \).
6. Let \( \text{formatNumberResult} \) be \( \text{FormatNumericToString}(\text{numberFormat}, x) \).
7. If \( \text{formatNumberResult}.[[\text{RoundedNumber}]] = 0 \), then
   a. Return \( \text{exponent} \).
8. Let \( \text{newMagnitude} \) be the base 10 logarithm of \( \text{formatNumberResult}.[[\text{RoundedNumber}]] \) rounded down to the nearest integer.
9. If newMagnitude is magnitude – exponent, then
   a. Return exponent.
10. Return ComputeExponentForMagnitude(numberFormat, magnitude + 1).

15.5.14 ComputeExponentForMagnitude ( numberFormat, magnitude )

The abstract operation ComputeExponentHelper computes an exponent by which to scale a number of the
given magnitude (power of ten of the most significant digit) according to the locale and the desired notation
(scientific, engineering, or compact).

1. Let notation be numberFormat.[[Notation]].
2. If notation is "standard", then
   a. Return 0.
3. Else if notation is "scientific", then
   a. Return magnitude.
4. Else if notation is "engineering", then
   a. Let thousands be the greatest integer that is not greater than magnitude / 3.
   b. Return thousands × 3.
5. Else,
   a. Assert: notation is "compact".
   b. Let exponent be an implementation- and locale-dependent (ILD) integer by which to scale a number of
      the given magnitude in compact notation for the current locale.
   c. Return exponent.

16 PluralRules Objects

16.1 The Intl.PluralRules Constructor

The PluralRules constructor is the %PluralRules% intrinsic object and a standard built-in property of the Intl
object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

16.1.1 Intl.PluralRules ([ locales [ , options ] ])

When the Intl.PluralRules function is called with optional arguments locales and options, the following
steps are taken:

1. If NewTarget is undefined, throw a TypeError exception.
2. Let pluralRules be ? OrdinaryCreateFromConstructor(NewTarget, "%PluralRules.prototype%", «
   [[InitializedPluralRules]], [[Locale]], [[Type]], [[MinimumIntegerDigits]], [[MinimumFractionDigits]],
   [[MaximumFractionDigits]], [[MinimumSignificantDigits]], [[MaximumSignificantDigits]],
   [[RoundingType]] »).

16.1.2 InitializePluralRules ( pluralRules, locales, options )
The abstract operation `InitializePluralRules` accepts the arguments `pluralRules` (which must be an object), `locales`, and `options`. It initializes `pluralRules` as a PluralRules object. The following steps are taken:

1. Let `requestedLocales` be `CanonicalizeLocaleList(locales)`.
2. Set `options` to `CoerceOptionsToObject(options)`.
3. Let `opt` be a new Record.
5. Set `opt.[[localeMatcher]]` to `matcher`.
7. Set `pluralRules.[[Type]]` to `t`.
8. Perform `SetNumberFormatDigitOptions(pluralRules, options, +0\textsubscript{p}, 3\textsubscript{p}, "standard")`.
9. Let `localeData` be `%PluralRules%.[[LocaleData]]`.
10. Let `r` be `ResolveLocale(%PluralRules%.[[AvailableLocales]], requestedLocales, opt, %PluralRules%. [[relevantExtensionKeys]], localeData)`.
11. Set `pluralRules.[[Locale]]` to `r.[[locale]]`.
12. Return `pluralRules`.

### 16.2 Properties of the Intl.PluralRules Constructor

The Intl.PluralRules constructor has the following properties:

#### 16.2.1 Intl.PluralRules.prototype

The value of `Intl.PluralRules.prototype` is `%PluralRules.prototype%`. This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }.

#### 16.2.2 Intl.PluralRules.supportedLocalesOf ( locales [ , options ] )

When the `supportedLocalesOf` method is called with arguments `locales` and `options`, the following steps are taken:

1. Let `availableLocales` be `%PluralRules%.[[AvailableLocales]]`.
2. Let `requestedLocales` be `CanonicalizeLocaleList(locales)`.
3. Return `SupportedLocales(availableLocales, requestedLocales, options)`.

### 16.2.3 Internal slots

The value of the `[[AvailableLocales]]` internal slot is implementation-defined within the constraints described in 9.1.

The value of the `[[relevantExtensionKeys]]` internal slot is « ».

**NOTE 1** Unicode Technical Standard 35 describes no locale extension keys that are relevant to the pluralization process.

The value of the `[[LocaleData]]` internal slot is implementation-defined within the constraints described in 9.1.
16.3 Properties of the Intl.PluralRules Prototype Object

The Intl.PluralRules prototype object is itself an ordinary object. \%PluralRules.prototype\% is not an Intl.PluralRules instance and does not have an [[InitializedPluralRules]] internal slot or any of the other internal slots of Intl.PluralRules instance objects.

16.3.1 Intl.PluralRules.prototype.constructor

The initial value of Intl.PluralRules.prototype.constructor is \%PluralRules\%.

16.3.2 Intl.PluralRules.prototype [ @@toStringTag ]

The initial value of the @@toStringTag property is the String value "Intl.PluralRules".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

16.3.3 Intl.PluralRules.prototype.select ( value )

When the select method is called with an argument value, the following steps are taken:

1. Let pr be the this value.
2. Perform ? RequireInternalSlot(pr, [[InitializedPluralRules]]).
3. Let n be ? ToNumber(value).

16.3.4 Intl.PluralRules.prototype.resolvedOptions ( )

This function provides access to the locale and options computed during initialization of the object.

1. Let pr be the this value.
2. Perform ? RequireInternalSlot(pr, [[InitializedPluralRules]]).
3. Let options be ! OrdinaryObjectCreate(%Object.prototype%).
4. For each row of Table 13, except the header row, in table order, do
   a. Let p be the Property value of the current row.
   b. Let v be the value of pr’s internal slot whose name is the Internal Slot value of the current row.
   c. If v is not undefined, then
      i. Perform ! CreateDataPropertyOrThrow(options, p, v).
5. Let pluralCategories be a List of Strings containing all possible results of PluralRuleSelect for the selected locale pr.[[Locale]].
6. Perform ! CreateDataProperty(options, "pluralCategories", ! CreateArrayFromList(pluralCategories)).
7. Return options.

Table 13: Resolved Options of PluralRules Instances

<table>

</tr>
</thead>
</table>

© Ecma International
### 16.4 Properties of Intl.PluralRules Instances

Intl.PluralRules instances are ordinary objects that inherit properties from %PluralRules.prototype%. Intl.PluralRules instances have an [[InitializedPluralRules]] internal slot.

Intl.PluralRules instances also have several internal slots that are computed by the constructor:

- [[Locale]] is a String value with the language tag of the locale whose localization is used by the plural rules.
- [[Type]] is one of the String values "cardinal" or "ordinal", identifying the plural rules used.
- [[MinimumIntegerDigits]] is a non-negative integer Number value indicating the minimum integer digits to be used.
- [[MinimumFractionDigits]] and [[MaximumFractionDigits]] are non-negative integer Number values indicating the minimum and maximum fraction digits to be used. Numbers will be rounded or padded with trailing zeroes if necessary.
- [[MinimumSignificantDigits]] and [[MaximumSignificantDigits]] are positive integer Number values indicating the minimum and maximum fraction digits to be used. Either none or both of these properties are present; if they are, they override minimum and maximum integer and fraction digits.
- [[RoundingType]] is one of the values fractionDigits or significantDigits, indicating which rounding strategy to use, as discussed in 15.4.

### 16.5 Abstract Operations for PluralRules Objects

#### 16.5.1 GetOperands ( s )

The abstract operation GetOperands takes argument s (a decimal String). It extracts numeric features from s that correspond with the operands of Unicode Technical Standard #35, Part 3, Section 5.1.1. It performs the following steps when called:

1. Let \( n \) be ! ToNumber(s).
2. Assert: \( n \) is finite.
3. Let \( dp \) be ! StringIndexOf(s, ".", 0).
4. If \( dp = -1 \), then
   a. Let \( intPart \) be \( n \).
   b. Let \( fracSlice \) be "".
5. Else,
   a. Let \( intPart \) be the substring of \( s \) from 0 to \( dp \).
   b. Let \( fracSlice \) be the substring of \( s \) from \( dp + 1 \).
6. Let \( i \) be abs(! ToNumber(intPart)).
7. Let \( fracDigitCount \) be the length of \( fracSlice \).
8. Let \( f \) be ! ToNumber(fracSlice).
9. Let \( significantFracSlice \) be the value of \( fracSlice \) stripped of trailing "0".
10. Let \( significantFracDigitCount \) be the length of \( significantFracSlice \).
11. Let \( significantFrac \) be ! ToNumber(significantFracSlice).
12. Return a new Record { 
    [[Number]]: abs(n), 
    [[IntegerDigits]]: \( i \), 
    [[FractionDigits]]: \( f \), 
    [[NumberOfFractionDigits]]: \( fracDigitCount \), 
    [[FractionDigitsWithoutTrailing]]: \( significantFrac \), 
    [[NumberOfFractionDigitsWithoutTrailing]]: \( significantFracDigitCount \) 
  }.

</tbody>
</table>

16.5.2 PluralRuleSelect ( locale, type, n, operands )

The implementation-defined abstract operation PluralRuleSelect takes arguments locale (a String), type (a String), \( n \) (a finite Number), and operands (a Plural Rules Operands Record derived from formatting \( n \)). It returns the String from « "zero", "one", "two", "few", "many", "other" » that best categorizes the operands representation of \( n \) according to the rules for locale and type.

16.5.3 ResolvePlural ( pluralRules, n )

When the ResolvePlural abstract operation is called with arguments pluralRules (which must be an object initialized as a PluralRules) and \( n \) (which must be a Number value), it returns a String value representing the
plural form of \( n \) according to the effective locale and the options of \textit{pluralRules}. The following steps are taken:

1. Assert: Type(\textit{pluralRules}) is Object.
2. Assert: \textit{pluralRules} has an [[InitializedPluralRules]] internal slot.
3. Assert: Type(\( n \)) is Number.
4. If \( n \) is not a finite Number, then
   a. Return "other".
5. Let \textit{locale} be \textit{pluralRules}.[[Locale]].
6. Let \textit{type} be \textit{pluralRules}.[[Type]].
7. Let \textit{res} be ! FormatNumericToString(\textit{pluralRules}, \( n \)).
8. Let \( s \) be \textit{res}.[[FormattedString]].
9. Let \textit{operands} be ! GetOperands(\( s \)).
10. Return ! PluralRuleSelect(\textit{locale}, \textit{type}, \( n \), \textit{operands}).

17 RelativeTimeFormat Objects

17.1 The Intl.RelativeTimeFormat Constructor

The RelativeTimeFormat constructor is the %RelativeTimeFormat% intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

17.1.1 Intl.RelativeTimeFormat ([ locales [ , options ] ])

When the Intl.RelativeTimeFormat function is called with optional arguments \textit{locales} and \textit{options}, the following steps are taken:

1. If NewTarget is \texttt{undefined}, throw a TypeError exception.

17.1.2 InitializeRelativeTimeFormat ( relativeTimeFormat, locales, options )

The abstract operation InitializeRelativeTimeFormat accepts the arguments \textit{relativeTimeFormat} (which must be an object), \textit{locales}, and \textit{options}. It initializes \textit{relativeTimeFormat} as a RelativeTimeFormat object.

The following algorithm refers to the \textit{type} nonterminal from UTS 35's Unicode Locale Identifier grammar. The following steps are taken:

1. Let \textit{requestedLocales} be ? CanonicalizeLocaleList(locales).
2. Set \textit{options} to ? CoerceOptionsToObject(options).
3. Let \textit{opt} be a new Record.
5. Set \textit{opt}.[[LocaleMatcher]] to \textit{matcher}.
7. If `numberingSystem` is not `undefined`, then
   a. If `numberingSystem` does not match the Unicode Locale Identifier type nonterminal, throw a `RangeError` exception.
8. Set `opt.[[nu]]` to `numberingSystem`.
9. Let `localeData` be `%RelativeTimeFormat%.[[LocaleData]].
10. Let `r` be `ResolveLocale(%RelativeTimeFormat%.[[AvailableLocales]], requestedLocales, opt, %RelativeTimeFormat%.[[RelevantExtensionKeys]], localeData).
11. Let `locale` be `r.[[locale]]`.
12. Set `relativeTimeFormat.[[Locale]]` to `locale`.
13. Set `relativeTimeFormat.[[DataLocale]]` to `r.[[dataLocale]]`.
14. Set `relativeTimeFormat.[[NumberingSystem]]` to `r.[[nu]]`.
16. Set `relativeTimeFormat.[[Style]]` to `style`.
18. Set `relativeTimeFormat.[[Numeric]]` to `numeric`.
19. Let `relativeTimeFormat.[[NumberFormat]]` be ! `Construct(%NumberFormat%, « locale »)`.

### 17.2 Properties of the Intl.RelativeTimeFormat Constructor

The Intl.RelativeTimeFormat constructor has the following properties:

#### 17.2.1 Intl.RelativeTimeFormat.prototype

The value of `Intl.RelativeTimeFormat.prototype` is `%RelativeTimeFormat.prototype%`.

This property has the attributes `[[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false`.

#### 17.2.2 Intl.RelativeTimeFormat.supportedLocalesOf ( locales [ , options ] )

When the `supported LocalesOf` method is called with arguments `locales` and `options`, the following steps are taken:

1. Let `availableLocales` be `%RelativeTimeFormat%.[[AvailableLocales]].
2. Let `requestedLocales` be ? `CanonicalizeLocaleList(locales)`.

#### 17.2.3 Internal slots

The value of the `[[AvailableLocales]]` internal slot is implementation-defined within the constraints described in 9.1.

The value of the `[[RelevantExtensionKeys]]` internal slot is « "nu" ».

NOTE 1 Unicode Technical Standard 35 describes one locale extension key that is relevant to relative time formatting: "nu" for numbering system (of formatted numbers).
The value of the [[LocaleData]] internal slot is implementation-defined within the constraints described in 9.1 and the following additional constraints, for all locale values `locale`:

- `[[LocaleData]][[locale]]` has fields "second", "minute", "hour", "day", "week", "month", "quarter", and "year". Additional fields may exist with the previous names concatenated with the strings "-narrow" or "-short". The values corresponding to these fields are Records which contain these two categories of fields:
  - "future" and "past" fields, which are Records with a field for each of the plural categories relevant for `locale`. The value corresponding to those fields is a pattern which may contain "{0}" to be replaced by a formatted number.
  - Optionally, additional fields whose key is the result of `ToString` of a Number, and whose values are literal Strings which are not treated as templates.
- The list that is the value of the "nu" field of any locale field of `[[LocaleData]]` must not include the values "native", "traditio", or "finance".

**NOTE 2**
It is recommended that implementations use the locale data provided by the Common Locale Data Repository (available at https://cldr.unicode.org/).

### 17.3 Properties of the Intl.RelativeTimeFormat Prototype Object

The Intl.RelativeTimeFormat prototype object is itself an ordinary object. `%RelativeTimeFormat.prototype%` is not an Intl.RelativeTimeFormat instance and does not have an `[[InitializedRelativeTimeFormat]]` internal slot or any of the other internal slots of Intl.RelativeTimeFormat instance objects.

#### 17.3.1 Intl.RelativeTimeFormat.prototype.constructor

The initial value of `Intl.RelativeTimeFormat.prototype.constructor` is `%RelativeTimeFormat%`.

#### 17.3.2 Intl.RelativeTimeFormat.prototype[ @@toStringTag ]

The initial value of the `@@toStringTag` property is the String value "Intl.RelativeTimeFormat". This property has the attributes `{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

#### 17.3.3 Intl.RelativeTimeFormat.prototype.format ( value, unit )

When the `format` method is called with arguments `value` and `unit`, the following steps are taken:

1. Let `relativeTimeFormat` be the this value.
3. Let `value` be ? `ToNumber`(`value`).
4. Let `unit` be ? `ToString`(`unit`).

#### 17.3.4 Intl.RelativeTimeFormat.prototype.formatToParts ( value, unit )

When the `formatToParts` method is called with arguments `value` and `unit`, the following steps are taken:
1. Let `relativeTimeFormat` be the this value.
3. Let `value` be ? `ToNumber(value)`.
4. Let `unit` be ? `ToString(unit)`.
5. Return ? `FormatRelativeTimeToParts(relativeTimeFormat, value, unit)`.

**17.3.5 Intl.RelativeTimeFormat.prototype.resolvedOptions()**

This function provides access to the locale and options computed during initialization of the object.

1. Let `relativeTimeFormat` be the this value.
3. Let `options` be ! `OrdinaryObjectCreate(%Object.prototype%)`.
4. For each row of Table 15, except the header row, in table order, do
   a. Let `p` be the Property value of the current row.
   b. Let `v` be the value of `relativeTimeFormat`'s internal slot whose name is the Internal Slot value of the current row.
   c. Assert: `v` is not undefined.
   d. Perform ! `CreateDataPropertyOrThrow(options, p, v)`.
5. Return `options`.

<table>
<thead>
<tr>

<td>&quot;numberingSystem&quot;</td>
</tr>
</tbody>
</table>

**17.4 Properties of Intl.RelativeTimeFormat Instances**

Intl.RelativeTimeFormat instances are ordinary objects that inherit properties from `%RelativeTimeFormat.prototype%`.

Intl.RelativeTimeFormat instances have an `[[InitializedRelativeTimeFormat]]` internal slot.

Intl.RelativeTimeFormat instances also have several internal slots that are computed by the constructor:

- `[[Locale]]` is a String value with the language tag of the locale whose localization is used for formatting.
- `[[DataLocale]]` is a String value with the language tag of the nearest locale for which the implementation has data to perform the formatting operation. It will be a parent locale of `[[Locale]]`.
- `[[Style]]` is one of the String values "long", "short", or "narrow", identifying the relative time format style used.
- `[[Numeric]]` is one of the String values "always" or "auto", identifying whether numerical descriptions are always used, or used only when no more specific version is available (e.g., “1 day ago” vs “yesterday”).
- `[[NumberFormat]]` is an Intl.NumberFormat object used for formatting.
• [[NumberingSystem]] is a String value with the "type" given in Unicode Technical Standard 35 for the numbering system used for formatting.

• [[PluralRules]] is an Intl.PluralRules object used for formatting.

17.5 Abstract Operations for RelativeTimeFormat Objects

17.5.1 SingularRelativeTimeUnit (unit)

1. Assert: Type(unit) is String.
2. If unit is "seconds", return "second".
3. If unit is "minutes", return "minute".
4. If unit is "hours", return "hour".
5. If unit is "days", return "day".
6. If unit is "weeks", return "week".
7. If unit is "months", return "month".
8. If unit is "quarters", return "quarter".
9. If unit is "years", return "year".
10. If unit is not one of "second", "minute", "hour", "day", "week", "month", "quarter", or "year", throw a RangeError exception.
11. Return unit.

17.5.2 PartitionRelativeTimePattern (relativeTimeFormat, value, unit)

When the PartitionRelativeTimePattern abstract operation is called with arguments relativeTimeFormat, value, and unit it returns a String value representing value (which must be a Number value) according to the effective locale and the formatting options of relativeTimeFormat.

1. Assert: relativeTimeFormat has an [InitializedRelativeTimeFormat] internal slot.
2. Assert: Type(value) is Number.
3. Assert: Type(unit) is String.
4. If value is NaN, +∞𝔽, or -∞𝔽, throw a RangeError exception.
5. Let unit be ? SingularRelativeTimeUnit(unit).
6. Let localeData be %RelativeTimeFormat%.[[LocaleData]].
7. Let dataLocale be relativeTimeFormat.[[DataLocale]].
8. Let fields be localeData.[[dataLocale]].
9. Let style be relativeTimeFormat.[[Style]].
10. If style is equal to "short", then
    a. Let entry be the string-concatenation of unit and "-short".
11. Else if style is equal to "narrow", then
    a. Let entry be the string-concatenation of unit and "-narrow".
12. Else,
    a. Let entry be unit.
13. If fields doesn't have a field [[<entry>]], then
    a. Let entry be unit.
14. Let patterns be fields.[[<entry>]].
15. Let numeric be relativeTimeFormat.[[Numeric]].
16. If numeric is equal to "auto", then
a. Let `valueString` be `ToString(value)`.
b. If `patterns` has a field `[[valueString>]]`, then
   i. Let `result` be `patterns.[[<valueString>]]`.
   ii. Return a List containing the Record `[[Type]]: "literal", [[Value]]: `result` `}`.
17. If `value` is `-0𝔽` or if `value` is less than 0, then
   a. Let `tl` be "past".
18. Else,
   a. Let `tl` be "future".
19. Let `po` be `patterns.[[<tl>]]`.
20. Let `fc` be ! `PartitionNumberPattern(relativeTimeFormat.[[NumberFormat]], value)`.
22. Let `pattern` be `po.[[<pr>]]`.
23. Return ! `MakePartsList(pattern, unit, fc)`.

17.5.3 MakePartsList ( `pattern, unit, parts` )

The MakePartsList abstract operation is called with arguments `pattern`, a pattern String, `unit`, a String, and `parts`, a List of Records representing a formatted Number.

NOTE  Example:

1. Return ! `MakePartsList("AA{0}BB", "hour", « Record { [[Type]]: "integer", [[Value]]: "15" } »)`.

will return a List of Records like

```
«
  { [[Type]]: "literal", [[Value]]: "AA", [[Unit]]: empty },
  { [[Type]]: "integer", [[Value]]: "15", [[Unit]]: "hour" },
  { [[Type]]: "literal", [[Value]]: "BB", [[Unit]]: empty }
»
```

1. Let `patternParts` be `PartitionPattern(pattern)`.
2. Let `result` be a new empty `List`.
3. For each Record `[[Type]], [[Value]]` `patternPart` in `patternParts`, do
   a. If `patternPart.[[Type]]` is "literal", then
      i. Append Record `[[Type]]: "literal", [[Value]]: `patternPart.[[Value]], [[Unit]]: empty` `}` to `result`.
   b. Else,
      i. `Assert: patternPart.[[Type]]` is "0".
      ii. For each Record `[[Type]], [[Value]]` `part` in `parts`, do
          1. Append Record `[[Type]]: part.[[Type]], [[Value]]: part.[[Value]], [[Unit]]: `unit` `}` to `result`.
4. Return `result`.

17.5.4 FormatRelativeTime ( `relativeTimeFormat`, `value`, `unit` )

The FormatRelativeTime abstract operation is called with arguments `relativeTimeFormat` (which must be an object initialized as a RelativeTimeFormat), `value` (which must be a Number value), and `unit` (which must be a String denoting the value unit) and performs the following steps:
1. Let parts be \( \text{PartitionRelativeTimePattern}(relative\text{-}TimeFormat, \text{value}, \text{unit}) \).
2. Let result be an empty String.
3. For each Record \([[[\text{Type}}], [[[\text{Value}}], [[[\text{Unit}}]]] \) part in parts, do
   a. Set result to the string-concatenation of result and part.\([[[\text{Value}}]]].
4. Return result.

### 17.5.5 FormatRelativeTimeToParts (relative\text{-}TimeFormat, \text{value}, \text{unit})

The FormatRelativeTimeToParts abstract operation is called with arguments relative\text{-}TimeFormat (which must be an object initialized as a RelativeTimeFormat), \text{value} (which must be a Number value), and \text{unit} (which must be a String denoting the value unit) and performs the following steps:

1. Let parts be \( \text{PartitionRelativeTimePattern}(relative\text{-}TimeFormat, \text{value}, \text{unit}) \).
2. Let result be \! ArrayCreate(0).
3. Let \( n \) be 0.
4. For each Record \([[[\text{Type}}], [[[\text{Value}}], [[[\text{Unit}}]]] \) part in parts, do
   a. Let \( O \) be \! OrdinaryObjectCreate(%Object.prototype\%).
   b. Perform \! CreateDataPropertyOrThrow\( (O, "type", part.\[[[\text{Type}}]]) \).
   c. Perform \! CreateDataPropertyOrThrow\( (O, "value", part.\[[[\text{Value}}]]) \).
   d. If part.\[[[\text{Unit}}]] is not empty, then
      i. Perform \! CreateDataPropertyOrThrow\( (O, "unit", part.\[[[\text{Unit}}]]) \).
   e. Perform \! CreateDataPropertyOrThrow\( (result, ! \text{ToString}(n), O) \).
   f. Increment \( n \) by 1.
5. Return result.

## 18 Segmenter Objects

### 18.1 The Intl.Segmenter Constructor

The Segmenter constructor is the \( \%\text{Segmenter}\% \) intrinsic object and a standard built-in property of the Intl object. Behaviour common to all service constructor properties of the Intl object is specified in 9.1.

#### 18.1.1 Intl.Segmenter ([ locales [, options ] ])

When the Intl.Segmenter function is called with optional arguments locales and options, the following steps are taken:

1. If NewTarget is \text{undefined}, throw a TypeError exception.
2. Let internalSlotsList be \([[[\text{InitializedSegmenter}}], [[\text{Locale}}], [[\text{SegmenterGranularity}}]] \) ».
3. Let segmenter be \? OrdinaryCreateFromConstructor(NewTarget, \ "%\text{Segmenter.prototype}\%", internalSlotsList).
4. Let requestedLocales be \? CanonicalizeLocaleList(locales).
5. Set options to \? GetOptionsObject(options).
6. Let opt be a new Record.
7. Let matcher be \? GetOption(options, "localeMatcher", "string", « "lookup", "best fit" », "best fit").
8. Set \texttt{opt.[localeMatcher]} to \textit{matcher}.
9. Let \texttt{localeData} be \texttt{%Segmenter%.[[LocaleData]]}.
10. Let \texttt{r} be \texttt{ResolveLocale(%Segmenter%.[[AvailableLocales]], requestedLocales, opt, %Segmenter%.[[AvailableLocales]], localeData)}.
11. Set \texttt{segmenter.[[Locale]]} to \texttt{r.[[locale]]}.
12. Let \texttt{granularity} be \texttt{? GetOption(options, "granularity", "string", "grapheme", "word", "sentence", "grapheme")}.
13. Set \texttt{segmenter.[[SegmenterGranularity]]} to \texttt{granularity}.
14. Return \texttt{segmenter}.

18.2 Properties of the Intl.Segmenter Constructor

The Intl.Segmenter constructor has the following properties:

18.2.1 Intl.Segmenter.prototype

The value of \texttt{Intl.Segmenter.prototype} is \texttt{%Segmenter.prototype%}.

This property has the attributes \{ [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false \}.

18.2.2 Intl.Segmenter.supportedLocalesOf ( locales [, options ] )

When the \texttt{supportedLocalesOf} method is called with arguments \texttt{locales} and \texttt{options}, the following steps are taken:

1. Let \texttt{availableLocales} be \texttt{%Segmenter%.[[AvailableLocales]]}.
2. Let \texttt{requestedLocales} be \texttt{? CanonicalizeLocaleList(locales)}.
3. Return \texttt{? SupportedLocales(availableLocales, requestedLocales, options)}.

18.2.3 Internal slots

The value of the [[AvailableLocales]] internal slot is implementation-defined within the constraints described in 9.1.

The value of the [[RelevantExtensionKeys]] internal slot is « ».

\begin{quote}
\textbf{NOTE} \hspace{1em} Intl.Segmenter does not have any relevant extension keys.
\end{quote}

The value of the [[LocaleData]] internal slot is implementation-defined within the constraints described in 9.1.

18.3 Properties of the Intl.Segmenter Prototype Object

The Intl.Segmenter prototype object is itself an ordinary object. \texttt{%Segmenter.prototype%} is not an Intl.Segmenter instance and does not have an [[InitializedSegmenter]] internal slot or any of the other internal slots of Intl.Segmenter instance objects.
18.3.1 Intl.Segmenter.prototype.constructor

The initial value of `Intl.Segmenter.prototype.constructor` is `%Segmenter%`.

18.3.2 Intl.Segmenter.prototype [ @@toStringTag ]

The initial value of the @@toStringTag property is the String value "Intl.Segmenter".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

18.3.3 Intl.Segmenter.prototype.segment ( `string` )

The `Intl.Segmenter.prototype.segment` method is called on an Intl.Segmenter instance with argument `string` to create a Segments instance for the string using the locale and options of the Intl.Segmenter instance. The following steps are taken:

1. Let `segmenter` be the this value.
2. Perform ? RequireInternalSlot(`segmenter`, [[InitializedSegmenter]]).
3. Let `string` be ? ToString(`string`).
4. Return ! CreateSegmentsObject(`segmenter`, `string`).

18.3.4 Intl.Segmenter.prototype.resolvedOptions ( )

This function provides access to the locale and options computed during initialization of the object.

1. Let `segmenter` be the this value.
2. Perform ? RequireInternalSlot(`segmenter`, [[InitializedSegmenter]]).
3. Let `options` be ! OrdinaryObjectCreate(%Object.prototype%).
4. For each row of Table 16, except the header row, in table order, do
   a. Let `p` be the Property value of the current row.
   b. Let `v` be the value of `segmenter`'s internal slot whose name is the Internal Slot value of the current row.
   c. Assert: `v` is not undefined.
   d. Perform ! CreateDataPropertyOrThrow(`options`, `p`, `v`).
5. Return `options`.

Table 16: Resolved Options of Segmenter Instances

<table>
<thead>
<tr>
<th>Internal Slot</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[Locale]]</td>
<td>&quot;locale&quot;</td>
</tr>
<tr>
<td>[[SegmenterGranularity]]</td>
<td>&quot;granularity&quot;</td>
</tr>
</tbody>
</table>

18.4 Properties of Intl.Segmenter Instances

Intl.Segmenter instances are ordinary objects that inherit properties from `%Segmenter.prototype%`.

Intl.Segmenter instances have an [[InitializedSegmenter]] internal slot.

Intl.Segmenter instances also have internal slots that are computed by the constructor:
• [[Locale]] is a String value with the language tag of the locale whose localization is used for segmentation.
• [[SegmenterGranularity]] is one of the String values "grapheme", "word", or "sentence", identifying the kind of text element to segment.

18.5 Segments Objects

A Segments instance is an object that represents the segments of a specific string, subject to the locale and options of its constructing Intl.Segmenter instance.

18.5.1 CreateSegmentsObject (segmenter, string)

The CreateSegmentsObject abstract operation is called with arguments Intl.Segmenter instance `segmenter` and String value `string` to create a Segments instance referencing both. The following steps are taken:

1. Let `internalSlotsList` be « [[SegmentsSegmenter]], [[SegmentsString]] ».
2. Let `segments` be ! OrdinaryObjectCreate(%SegmentsPrototype%, `internalSlotsList`).
3. Set `segments`.[[SegmentsSegmenter]] to `segmenter`.
4. Set `segments`.[[SegmentsString]] to `string`.
5. Return `segments`.

18.5.2 The %SegmentsPrototype% Object

The `%SegmentsPrototype%` object:

• is the prototype of all Segments objects.
• is an ordinary object.
• has the following properties:

18.5.2.1 %SegmentsPrototype%.containing (index)

The `containing` method is called on a Segments instance with argument `index` to return a Segment Data object describing the segment in the string including the code unit at the specified index according to the locale and options of the Segments instance's constructing Intl.Segmenter instance. The following steps are taken:

1. Let `segments` be the this value.
2. Perform ? RequireInternalSlot(`segments`, [[SegmentsSegmenter]]).
3. Let `segmenter` be `segments`.[[SegmentsSegmenter]].
4. Let `string` be `segments`.[[SegmentsString]].
5. Let `len` be the length of `string`.
6. Let `n` be ? ToIntegerOrInfinity(`index`).
7. If `n < 0` or `n ≥ len`, return undefined.
8. Let `startIndex` be ! FindBoundary(`segmenter`, `string`, `n`, before).
9. Let `endIndex` be ! FindBoundary(`segmenter`, `string`, `n`, after).
10. Return ! CreateSegmentDataObject(`segmenter`, `string`, `startIndex`, `endIndex`).

18.5.2.2 %SegmentsPrototype% [ @@iterator ] ()
The `@@iterator` method is called on a `Segments` instance to create a Segment Iterator over its string using the locale and options of its constructing `Intl.Segmenter` instance. The following steps are taken:

1. Let `segments` be the `this` value.
2. Perform `? RequireInternalSlot(segments, [[SegmentsSegmenter]])`.
3. Let `segmenter` be `segments`.[[SegmentsSegmenter]].
4. Let `string` be `segments`.[[SegmentsString]].
5. Return `! CreateSegmentIterator(segmenter, string)`.

18.5.3 Properties of Segments Instances

Segments instances are ordinary objects that inherit properties from `%SegmentsPrototype%`.

Segments instances have a `[[SegmentsSegmenter]]` internal slot that references the constructing `Intl.Segmenter` instance.

Segments instances have a `[[SegmentsString]]` internal slot that references the String value whose segments they expose.

18.6 Segment Iterator Objects

A Segment Iterator is an object that represents a particular iteration over the segments of a specific string.

18.6.1 CreateSegmentIterator ( `segmenter, string` )

The `CreateSegmentIterator` abstract operation is called with arguments `Intl.Segmenter` instance `segmenter` and String value `string` to create a Segment Iterator over `string` using the locale and options of `segmenter`. The following steps are taken:

1. Let `internalSlotsList` be « `[[IteratingSegmenter]], [[IteratedString]],
   [[IteratedStringNextSegmentCodeUnitIndex]] ».
2. Let `iterator` be `! OrdinaryObjectCreate(%SegmentIteratorPrototype%, internalSlotsList)`.
3. Set `iterator`.[[IteratingSegmenter]] to `segmenter`.
4. Set `iterator`.[[IteratedString]] to `string`.
5. Set `iterator`.[[IteratedStringNextSegmentCodeUnitIndex]] to 0.
6. Return `iterator`.

18.6.2 The `%SegmentIteratorPrototype% Object`

The `%SegmentIteratorPrototype%` object:

- is the prototype of all Segment Iterator objects.
- is an ordinary object.
- has a `[[Prototype]]` internal slot whose value is the intrinsic object `%Iterator.prototype%`.
- has the following properties:

18.6.2.1 `%SegmentIteratorPrototype%.next ( )`
The **next** method is called on a Segment Iterator instance to advance it forward one segment and return an *IteratorResult* object either describing the new segment or declaring iteration done. The following steps are taken:

1. Let `iterator` be the `this` value.
2. Perform `? RequireInternalSlot(iterator, [[IteratingSegmenter]])`.
3. Let `segmenter` be `iterator`.[[IteratingSegmenter]].
4. Let `string` be `iterator`.[[IteratedString]].
5. Let `startIndex` be `iterator`.[[IteratedStringNextSegmentCodeUnitIndex]].
6. Let `endIndex` be `! FindBoundary(segmenter, string, startIndex, after)`.
7. If `endIndex` is not finite, then
   a. Return `! CreateIterResultObject(undefined, true)`.
8. Set `iterator`.[[IteratedStringNextSegmentCodeUnitIndex]] to `endIndex`.
9. Let `segmentData` be `! CreateSegmentDataObject(segmenter, string, startIndex, endIndex)`.
10. Return `! CreateIterResultObject(segmentData, false)`.

### 18.6.2.2 `%SegmentIteratorPrototype%` [ @@toStringTag ]

The initial value of the @@toStringTag property is the String value "Segmenter String Iterator".

This property has the attributes { [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

### 18.6.3 Properties of Segment Iterator Instances

Segment Iterator instances are ordinary objects that inherit properties from `%SegmentIteratorPrototype%`. Segment Iterator instances are initially created with the internal slots described in **Table 17**.

<table>
<thead>
<tr>
<th>Internal Slot</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[IteratingSegmenter]]</td>
<td>The Intl.Segmenter instance used for iteration.</td>
</tr>
<tr>
<td>[[IteratedString]]</td>
<td>The String value being iterated upon.</td>
</tr>
<tr>
<td>[[IteratedStringNextSegmentCodeUnitIndex]]</td>
<td>The code unit index in the String value being iterated upon at the start of the next segment.</td>
</tr>
</tbody>
</table>

### 18.7 Segment Data Objects

A Segment Data object is an object that represents a particular segment from a string.

#### 18.7.1 CreateSegmentDataObject ( `segmenter, string, startIndex, endIndex` )

The CreateSegmentDataObject abstract operation is called with arguments Intl.Segmenter instance `segmenter`, String value `string`, and indices `startIndex` and `endIndex` within `string` to create a Segment Data object describing the segment within `string` from `segmenter` that is bounded by the indices. The following steps are taken:

1. Let `len` be the length of `string`.
2. Assert: `startIndex` ≥ 0.
3. Assert: `endIndex <= len`.
4. Assert: `startIndex < endIndex`.
5. Let `result` be `! OrdinaryObjectCreate(%Object.prototype%)`.
6. Let `segment` be the substring of `string` from `startIndex` to `endIndex`.
7. Perform `! CreateDataPropertyOrThrow(result, "segment", segment)`.
8. Perform `! CreateDataPropertyOrThrow(result, "index", F(startIndex))`.
9. Perform `! CreateDataPropertyOrThrow(result, "input", string)`.
10. Let `granularity` be `segmenter.[[SegmenterGranularity]]`.
11. If `granularity` is "word", then
   a. Let `isWordLike` be a Boolean value indicating whether the `segment` in `string` is "word-like" according to locale `segmenter.[[Locale]]`.
   b. Perform `! CreateDataPropertyOrThrow(result, "isWordLike", isWordLike)`.
12. Return `result`.

NOTE Whether a segment is "word-like" is implementation-dependent, and implementations are recommended to use locale-sensitive tailorings. In general, segments consisting solely of spaces and/or punctuation (such as those terminated with "WORD_NONE" boundaries by ICU [International Components for Unicode, documented at https://unicode-org.github.io/icu-docs/]) are not considered to be "word-like".

18.8 Abstract Operations for Segmenter Objects

18.8.1 FindBoundary ( `segmenter`, `string`, `startIndex`, `direction` )

The FindBoundary abstract operation is called with arguments Intl.Segmenter instance `segmenter`, String `string`, integer `startIndex`, and `direction` (which must be before or after) to find a segmentation boundary between two code units in `string` in the specified `direction` from the code unit at index `startIndex` according to the locale and options of `segmenter` and return the immediately following code unit index (which will be infinite if no such boundary exists). The following steps are taken:

NOTE Boundary determination is implementation-dependent, but general default algorithms are specified in Unicode Standard Annex 29 (available at https://www.unicode.org/reports/tr29/). It is recommended that implementations use locale-sensitive tailorings such as those provided by the Common Locale Data Repository (available at http://cldr.unicode.org).

1. Let `locale` be `segmenter.[[Locale]]`.
2. Let `granularity` be `segmenter.[[SegmenterGranularity]]`.
3. Let `len` be the length of `string`.
4. If `direction` is before, then
   a. Assert: `startIndex >= 0`.
   b. Assert: `startIndex < len`.
   c. Search `string` for the last segmentation boundary that is preceded by at most `startIndex` code units from the beginning, using locale `locale` and text element granularity `granularity`.
   d. If a boundary is found, return the count of code units in `string` preceding it.
   e. Return 0.
5. Assert: `direction` is after.
6. If \( \text{len} \) is 0 or \( \text{startIndex} \geq \text{len} \), return \(+\infty\).
7. Search \text{string} for the first segmentation boundary that follows the code unit at index \( \text{startIndex} \), using locale \text{locale} and text element granularity \text{granularity}.
8. If a boundary is found, return the count of code units in \text{string} preceding it.
9. Return \text{len}.

19 Locale Sensitive Functions of the ECMAScript Language Specification

The ECMAScript Language Specification, edition 10 or successor, describes several locale-sensitive functions. An ECMAScript implementation that implements this Internationalization API Specification shall implement these functions as described here.

NOTE The Collator, NumberFormat, or DateTimeFormat objects created in the algorithms in this clause are only used within these algorithms. They are never directly accessed by ECMAScript code and need not actually exist within an implementation.

19.1 Properties of the String Prototype Object

19.1.1 \text{String.prototype.localeCompare} ( \( \text{that} \[, \text{locales} \[, \text{options} \]\] )

This definition supersedes the definition provided in es2022, 21.1.3.10.

When the \text{localeCompare} method is called with argument \text{that} and optional arguments \text{locales}, and \text{options}, the following steps are taken:

1. Let \text{O} be \text{RequireObjectCoercible(this value)}.
2. Let \text{S} be \text{ToString(O)}.
3. Let \text{thatValue} be \text{ToString(that)}.
4. Let \text{collator} be \text{Construct(%Collator%, « locales, options »)}.
5. Return \text{CompareStrings(collator, S, thatValue)}.

The value of the "length" property of the \text{localeCompare} method is 1.

NOTE 1 The \text{localeCompare} method itself is not directly suitable as an argument to \text{Array.prototype.sort} because the latter requires a function of two arguments.

NOTE 2 The \text{localeCompare} function is intentionally generic; it does not require that its \text{this} value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

19.1.2 \text{String.prototype.toLocaleLowerCase} ( [ \text{locales} ] )

This definition supersedes the definition provided in es2022, 21.1.3.23.
This function interprets a String value as a sequence of code points, as described in es2022, 6.1.4. The following steps are taken:

1. Let \( O \) be ? RequireObjectCoercible(\( this \) value).
2. Let \( S \) be ? ToString(\( O \)).
3. Return ? TransformCase(\( S, \text{locales}, \text{lower} \)).

**NOTE**  The `toLocaleLowerCase` function is intentionally generic; it does not require that its `this` value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

**19.1.2.1 TransformCase ( \( S, \text{locales}, \text{targetCase} \))**

The abstract operation TransformCase takes arguments \( S \) (a String), `locales` (an ECMAScript language value), and `targetCase` (lower or upper). It interprets \( S \) as a sequence of UTF-16 encoded code points, as described in 6.1.4, and returns the result of implementation- and locale-dependent (ILD) transformation into `targetCase` as a new String value. It performs the following steps when called:

1. Let `requestedLocales` be ? CanonicalizeLocaleList(`locales`).
2. If `requestedLocales` is not an empty List, then
   a. Let `requestedLocale` be `requestedLocales`[0].
3. Else,
   a. Let `requestedLocale` be ! DefaultLocale().
4. Let `noExtensionsLocale` be the String value that is `requestedLocale` with any Unicode locale extension sequences (6.2.1) removed.
5. Let `availableLocales` be a List with language tags that includes the languages for which the Unicode Character Database contains language sensitive case mappings. Implementations may add additional language tags if they support case mapping for additional locales.
7. If `locale` is undefined, set `locale` to "und".
8. Let `codePoints` be ! StringToCodePoints(`S`).
9. If `targetCase` is lower, then
   a. Let `newCodePoints` be a List whose elements are the result of a lowercase transformation of `codePoints` according to an implementation-derived algorithm using `locale` or the Unicode Default Case Conversion algorithm.
10. Else,
    a. Assert: `targetCase` is upper.
    b. Let `newCodePoints` be a List whose elements are the result of an uppercase transformation of `codePoints` according to an implementation-derived algorithm using `locale` or the Unicode Default Case Conversion algorithm.

Code point mappings may be derived according to a tailored version of the Default Case Conversion Algorithms of the Unicode Standard. Implementations may use locale-sensitive tailoring defined in the file `SpecialCasing.txt` of the Unicode Character Database and/or CLDR and/or any other custom tailoring. Regardless of tailoring, a conforming implementation’s case transformation algorithm must always yield the same result given the same input code points, locale, and target case.
NOTE  
result may not be the same length as the input. Because both `toLocaleUpperCase` and `toLocaleLowerCase` have context-sensitive behaviour, the functions are not symmetrical. In other words, `s.toLocaleUpperCase().toLocaleLowerCase()` is not necessarily equal to `s.toLocaleLowerCase()` and `s.toLocaleLowerCase().toLocaleUpperCase()` is not necessarily equal to `s.toLocaleUpperCase()`.

19.1.3 String.prototype.toLocaleUpperCase ([ `locales` ])

This definition supersedes the definition provided in es2022, 21.1.3.24.

This function interprets a String value as a sequence of code points, as described in es2022, 6.1.4. The following steps are taken:

1. Let `O` be ? RequireObjectCoercible(this value).
2. Let `S` be ? ToString(O).

NOTE  
The `toLocaleUpperCase` function is intentionally generic; it does not require that its this value be a String object. Therefore, it can be transferred to other kinds of objects for use as a method.

19.2 Properties of the Number Prototype Object

The following definition(s) refer to the abstract operation `thisNumberValue` as defined in es2022, 20.1.3.

19.2.1 Number.prototype.toLocaleString ([ `locales` [, `options` ] ])

This definition supersedes the definition provided in es2022, 20.1.3.4.

When the `toLocaleString` method is called with optional arguments `locales` and `options`, the following steps are taken:

1. Let `x` be ? `thisNumberValue`(this value).
2. Let `numberFormat` be ? Construct(%NumberFormat%, « locales, options »).

19.3 Properties of the BigInt Prototype Object

The following definition(s) refer to the abstract operation `thisBigIntValue` as defined in es2022, 20.2.3.

19.3.1 BigInt.prototype.toLocaleString ([ `locales` [, `options` ] ])

This definition supersedes the definition provided in es2022, 20.2.3.2.

When the `toLocaleString` method is called with optional arguments `locales` and `options`, the following steps are taken:
1. Let \( x \) be \( \text{thisBigIntValue(this value)} \).
2. Let \( \text{numberFormat} \) be \( \text{Construct(\%NumberFormat\%, \"locales, options \")} \).
3. Return \( \text{FormatNumeric(numberFormat, x)} \).

19.4 Properties of the Date Prototype Object

The following definition(s) refer to the abstract operation \( \text{thisTimeValue} \) as defined in es2022, 20.4.4.

19.4.1 Date.prototype.toLocaleString ([ locales [, options ] ])

This definition supersedes the definition provided in es2022, 20.4.4.39.

When the \( \text{toLocaleString} \) method is called with optional arguments \( \text{locales} \) and \( \text{options} \), the following steps are taken:

1. Let \( x \) be \( \text{thisTimeValue(this value)} \).
2. If \( x \) is \( \text{NaN} \), return "Invalid Date".
3. Let \( \text{options} \) be \( \text{ToDateTimeOptions(options, "any", "all")} \).
4. Let \( \text{dateFormat} \) be \( \text{Construct(\%DateTimeFormat\%, \"locales, options \")} \).
5. Return \( \text{FormatDateTime(dateFormat, x)} \).

19.4.2 Date.prototype.toLocaleDateString ([ locales [, options ] ])

This definition supersedes the definition provided in es2022, 20.4.4.38.

When the \( \text{toLocaleDateString} \) method is called with optional arguments \( \text{locales} \) and \( \text{options} \), the following steps are taken:

1. Let \( x \) be \( \text{thisTimeValue(this value)} \).
2. If \( x \) is \( \text{NaN} \), return "Invalid Date".
3. Let \( \text{options} \) be \( \text{ToDateTimeOptions(options, "date", "date")} \).
4. Let \( \text{dateFormat} \) be \( \text{Construct(\%DateTimeFormat\%, \"locales, options \")} \).
5. Return \( \text{FormatDateTime(dateFormat, x)} \).

19.4.3 Date.prototype.toLocaleTimeString ([ locales [, options ] ])

This definition supersedes the definition provided in es2022, 20.4.4.40.

When the \( \text{toLocaleTimeString} \) method is called with optional arguments \( \text{locales} \) and \( \text{options} \), the following steps are taken:

1. Let \( x \) be \( \text{thisTimeValue(this value)} \).
2. If \( x \) is \( \text{NaN} \), return "Invalid Date".
3. Let \( \text{options} \) be \( \text{ToDateTimeOptions(options, "time", "time")} \).
4. Let \( \text{timeFormat} \) be \( \text{Construct(\%DateTimeFormat\%, \"locales, options \")} \).
5. Return \( \text{FormatDateTime(timeFormat, x)} \).
19.5 Properties of the Array Prototype Object

19.5.1 Array.prototype.toLocaleString ([ locales [, options ] ])

This definition supersedes the definition provided in es2022, 22.1.3.29.

When the `toLocaleString` method is called with optional arguments `locales` and `options`, the following steps are taken:

1. Let `array` be ? ToObject(this value).
2. Let `len` be ? ToLength(? Get(array, "length")).
3. Let `separator` be the implementation-defined list-separator String value appropriate for the host environment’s current locale (such as ", ").
4. Let `R` be the empty String.
5. Let `k` be 0.
6. Repeat, while `k < len`,
   a. If `k > 0`, then
      i. Set `R` to the string-concatenation of `R` and `separator`.
   b. Let `nextElement` be ? Get(array, ! ToString(k)).
   c. If `nextElement` is not undefined or null, then
      i. Let `S` be ? ToString(? Invoke(nextElement, "toLocaleString", « locales, options »)).
      ii. Set `R` to the string-concatenation of `R` and `S`.
   d. Increase `k` by 1.
7. Return `R`.

**NOTE 1** This algorithm’s steps mirror the steps taken in 22.1.3.29, with the exception that `Invoke(nextElement, "toLocaleString")` now takes `locales` and `options` as arguments.

**NOTE 2** The elements of the array are converted to Strings using their `toLocaleString` methods, and these Strings are then concatenated, separated by occurrences of an implementation-defined locale-sensitive separator String. This function is analogous to `toString` except that it is intended to yield a locale-sensitive result corresponding with conventions of the host environment’s current locale.

**NOTE 3** The `toLocaleString` function is intentionally generic; it does not require that its this value be an Array object. Therefore it can be transferred to other kinds of objects for use as a method.

A Implementation Dependent Behaviour

The following aspects of the ECMAScript 2022 Internationalization API Specification are implementation dependent:

- In all functionality:
  - Additional values for some properties of `options` arguments (2)
  - The default locale (6.2.4)
  - The default time zone (6.4.3)
The set of available locales for each constructor (9.1)
The BestFitMatcher algorithm (9.2.4)
The BestFitSupportedLocales algorithm (9.2.9)

In Collator:
- Support for the Unicode extensions keys "kf", "kn" and the parallel options properties "caseFirst", "numeric" (10.1.2)
- The set of supported "co" key values (collations) per locale beyond a default collation (10.2.3)
- The set of supported "kf" key values (case order) per locale (10.2.3)
- The set of supported "kn" key values (numeric collation) per locale (10.2.3)
- The default search sensitivity per locale (10.2.3)
- The sort order for each supported locale and options combination (10.3.3.1)

In DateTimeFormat:
- The BestFitFormatMatcher algorithm (11.1.2)
- The set of supported "ca" key values (calendars) per locale (11.2.3)
- The set of supported "nu" key values (numbering systems) per locale (11.2.3)
- The default hourCycle setting per locale (11.2.3)
- The set of supported date-time formats per locale beyond a core set, including the representations used for each component and the associated patterns (11.2.3)
- Localized weekday names, era names, month names, day period names, am/pm indicators, and time zone names (11.5.8)
- The calendric calculations used for calendars other than "gregory", and adjustments for local time zones and daylight saving time (11.5.8)
- The set of all known registered Zone and Link names of the IANA Time Zone Database and the information about their offsets from UTC and their daylight saving time rules (6.4)

In DisplayNames:
- The localized names (12.2.3)

In ListFormat:
- The patterns used for formatting values (13.2.3)

In Locale:
- Support for the Unicode extensions keys "kf", "kn" and the parallel options properties "caseFirst", "numeric" (14.1.1)

In NumberFormat:
- The set of supported "nu" key values (numbering systems) per locale (15.2.3)
- The patterns used for formatting values as decimal, percent, currency, or unit values per locale, with or without the sign, with or without accounting format for currencies, and in standard, compact, or scientific notation (15.5.6)
- Localized representations of NaN and Infinity (15.5.6)
- The implementation of numbering systems not listed in Table 12 (15.5.6)
- Localized decimal and grouping separators (15.5.6)
- Localized plus and minus signs (15.5.6)
- Localized digit grouping schemata (15.5.6)
- Localized magnitude thresholds for compact notation (15.5.6)
- Localized symbols for compact and scientific notation (15.5.6)
- Localized narrow, short, and long currency symbols and names (15.5.6)
- Localized narrow, short, and long unit symbols (15.5.6)

In PluralRules:
- List of Strings representing the possible results of plural selection and their corresponding order per locale. (16.1.2)
In RelativeTimeFormat:
- The set of supported "nu" key values (numbering systems) per locale (17.2.3)
- The patterns used for formatting values (17.2.3)

In Segmenter:
- Boundary determination algorithms (18.8.1)
- Classification of segments as "word-like" (18.7.1)

B Additions and Changes That Introduce Incompatibilities with Prior Editions

10.1, 15.1, 11.1 In ECMA-402, 1st Edition, constructors could be used to create Intl objects from arbitrary objects. This is no longer possible in 2nd Edition.

11.3.3 In ECMA-402, 1st Edition, the "length" property of the function object \( F \) was set to \(+0_F\). In 2nd Edition, "length" is set to \( 1_F \).

10.3.2 In ECMA-402, 7th Edition, the @@toStringTag property of Intl.Collator.prototype was set to "Object". In 8th Edition, @@toStringTag is set to "Intl.Collator".

11.3.2 In ECMA-402, 7th Edition, the @@toStringTag property of Intl.DateTimeFormat.prototype was set to "Object". In 8th Edition, @@toStringTag is set to "Intl.DateTimeFormat".

15.3.2 In ECMA-402, 7th Edition, the @@toStringTag property of Intl.NumberFormat.prototype was set to "Object". In 8th Edition, @@toStringTag is set to "Intl.NumberFormat".

16.3.2 In ECMA-402, 7th Edition, the @@toStringTag property of Intl.PluralRules.prototype was set to "Object". In 8th Edition, @@toStringTag is set to "Intl.PluralRules".

8.1.1 In ECMA-402, 7th Edition, the @@toStringTag property of Intl was not defined. In 8th Edition, @@toStringTag is set to "Intl".

15.1 In ECMA-402, 8th Edition, the NumberFormat constructor used to throw an error when style is "currency" and maximumFractionDigits was set to a value lower than the default fractional digits for that currency. This behaviour was corrected in the 9th edition, and it no longer throws an error.

C Colophon

This specification is authored on GitHub in a plaintext source format called Ecm markup. Ecm markup is an HTML and Markdown dialect that provides a framework and toolset for authoring ECMAScript specifications in plaintext and processing the specification into a full-featured HTML rendering that follows the editorial conventions for this document. Ecm markup builds on and integrates a number of other formats and technologies including Grammarkdown for defining syntax and Ecm markdown for authoring algorithm steps. PDF renderings of this specification are produced by printing the HTML rendering to a PDF.

Prior editions of this specification were authored using Word—the Ecm markup source text that formed the basis of this edition was produced by converting the ECMAScript 2015 Word document to Ecm markup using an automated conversion tool.
